`LogoutEvent`, `LoginEvent`	`CheckoutSupportedDeliveryModesQueryResetEvent`	feature-libs/checkout/base/root/events/checkout-delivery-mode-event.listener.ts:L142-L154
`CheckoutPaymentDetailsCreatedEvent`	`LoadUserPaymentMethodsEvent` (non anonimi), messaggio, reset query	feature-libs/checkout/base/root/events/checkout-payment-event.listener.ts:L44-L60
`CheckoutPaymentDetailsSetEvent`	reset query	feature-libs/checkout/base/root/events/checkout-payment-event.listener.ts:L62-L68
`LanguageSetEvent`, `CurrencySetEvent`	`CheckoutPaymentCardTypesQueryReloadEvent`	feature-libs/checkout/base/root/events/checkout-payment-event.listener.ts:L70-L82
`OrderPlacedEvent`	`RemoveCartEvent` + reset query	feature-libs/checkout/base/root/events/checkout-place-order-event.listener.ts:L24-L41
`LoadUserAddressesEvent` / `LoadUserPaymentMethodsEvent`	azioni NgRx legacy `UserActions.*`	feature-libs/checkout/base/root/events/checkout-legacy-store-event.listener.ts:L17-L70

La gerarchia degli eventi (`CheckoutEvent` astratto con `userId`, `cartId`, `cartCode`; sottofamiglie delivery address / delivery mode / payment; `CheckoutQueryReloadEvent` e `CheckoutQueryResetEvent` che estendono direttamente `CxEvent`) è in feature-libs/checkout/base/root/events/checkout.events.ts:L12-L203.

3.4 Gli step: configurazione, flow e `CheckoutStepService`

1. `CheckoutConfig` è una classe astratta `providedIn: 'root', useExisting: Config` con chiave `checkout` (`steps`, `express`, `defaultDeliveryMode`, `guest`, `guestUseSavedAddress`, `flows`), e augmenta `Config` di `@spartacus/core` (feature-libs/checkout/base/root/config/checkout-config.ts:L18-L55).
2. I default base sono 4 step — `deliveryAddress`, `deliveryMode`, `paymentDetails`, `reviewOrder` — con `express: false`, `defaultDeliveryMode: [FREE]`, `guest: false` (feature-libs/checkout/base/root/config/

default-checkout-config.ts:L10-L42). Ogni step punta a una rotta semantica; le rotte default sono checkoutLogin (checkout-login, authFlow: true), checkout, checkoutDeliveryAddress, checkoutDeliveryMode, checkoutPaymentDetails, checkoutReviewOrder (feature-libs/checkout/base/root/config/default-checkout-routing-config.ts:L9-L20).

3. CheckoutFlowOrchestratorService (root) legge baseSite.baseStore.paymentProvider una volta (subscribe nel costruttore) e getCheckoutFlow() restituisce checkout.flows[provider] se esiste, altrimenti l'intero oggetto checkout (feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L20-L44). CheckoutFlow ripete le stesse chiavi di checkout tranne flows (feature-libs/checkout/base/root/model/checkout-flow.model.ts:L10-L31).
4. CheckoutStepService (root) nel costruttore chiama resetSteps(): prende gli step dal flow dell'orchestratore, scarta quelli disabled, li clona con Object.assign ed emette su steps$ (feature-libs/checkout/base/components/services/checkout-step.service.ts:L57-L63, feature-libs/checkout/base/components/services/checkout-step.service.ts:L88-L100).
5. activeStepIndex$ confronta router.state.context.id con /${paths[0]} di ogni step (feature-libs/checkout/base/components/services/checkout-step.service.ts:L34-L55). next()/back() usano invece l'ActivatedRoute del componente; back() dal primo step torna a 'cart' (feature-libs/checkout/base/components/services/checkout-step.service.ts:L65-L73), e il testo del bottone è checkout.backToCart o common.back (feature-libs/checkout/base/components/services/checkout-step.service.ts:L81-L86).
6. disableEnableStep(type, disabled) muta lo step in allSteps e riemette su steps$ solo quelli abilitati (feature-libs/checkout/base/components/services/checkout-step.service.ts:L102-L113); getNextCheckoutStepUrl/getPreviousCheckoutStepUrl saltano gli step disabilitati (feature-libs/checkout/base/components/services/checkout-step.service.ts:L130-L166).
7. CheckoutConfigService legge express, guest e defaultDeliveryMode dal flow (calcolato una volta alla costruzione) (feature-libs/checkout/base/components/services/checkout-config.service.ts:L19-L37). getPreferredDeliveryMode() ordina in place per costo e applica le preferenze in cascata con findMatchingDeliveryMode ricorsivo, con fallback deliveryModes[0].code (feature-libs/checkout/base/components/services/checkout-config.service.ts:L58-L104).

3.5 Navigazione a /checkout: i guard

I guard non sono sulle rotte Angular: sono dichiarati nei cmsComponents e applicati da CmsGuardsService, che li istanzia con getLastValueSync(unifiedInjector.get(guardClass)), cioè dall'ultimo injector (anche lazy) che fornisce quel token (core-libs/storefront/cms-structure/services/cms-guards.service.ts:L36-L48, core-libs/core/src/lazy-loading/unified-injector.ts:L52-L67). Il mapping è (feature-libs/checkout/base/components/checkout-orchestrator/checkout-orchestrator.module.ts:L18-L25, feature-libs/checkout/base/components/checkout-delivery-address/checkout-delivery-address.module.ts:L35-L42, feature-libs/checkout/base/components/checkout-login/checkout-login.module.ts:L37-L44, feature-libs/checkout/base/components/checkout-order-summary/checkout-order-summary.module.ts:L16-L22, feature-libs/checkout/base/components/checkout-progress/checkout-progress.module.ts:L33-L40):

COMPONENTE CMS	GUARD
CheckoutOrchestrator	CheckoutAuthGuard, CartNotEmptyGuard, CheckoutGuard
CheckoutDeliveryAddress	CheckoutAuthGuard, CartNotEmptyGuard, CartValidationGuard
CheckoutDeliveryMode, CheckoutPaymentDetails, CheckoutPlaceOrder, CheckoutReviewOrder, review overview/payment/shipping	CheckoutAuthGuard, CartNotEmptyGuard
CheckoutProgress (+ mobile top/bottom)	CheckoutAuthGuard, CartNotEmptyGuard, CheckoutStepsSetGuard

COMPONENTE CMS	GUARD
GuestCheckoutLoginComponent	NotCheckoutAuthGuard
CheckoutOrderSummary	nessuno

1. CheckoutAuthGuard attende activeCartFacade.isStable(); utente loggato → true; anonimo con guest cart → true; altrimenti handleAnonymousUser() (feature-libs/checkout/base/components/guards/checkout-auth.guard.ts:L38-L57). Questo salva l'URL corrente e, con il toggle authorizationCodeFlowByDefault, scrive IS_GUEST_USER_CHECKOUT_KEY in localStorage (se guest abilitato) e redirige a login; senza toggle, se il guest è abilitato redirige a login?forced=true (feature-libs/checkout/base/components/guards/checkout-auth.guard.ts:L59-L77).
2. CartNotEmptyGuard redirige a home se totalItems è falsy (feature-libs/checkout/base/components/guards/cart-not-empty.guard.ts:L24-L39).
3. CheckoutGuard (solo sull'orchestrator) redirige alla prima rotta degli step; se express è attivo e il carrello non è guest, prova ExpressCheckoutService.trySetDefaultCheckoutDetails() e, se riesce, redirige al review order (feature-libs/checkout/base/components/guards/checkout.guard.ts:L22-L30, feature-libs/checkout/base/components/guards/checkout.guard.ts:L41-L70). Il componente CheckoutOrchestratorComponent ha template vuoto: esiste solo per agganciare questi guard alla pagina /checkout (feature-libs/checkout/base/components/checkout-orchestrator/checkout-orchestrator.component.ts:L9-L18).
4. ExpressCheckoutService costruisce nel costruttore una catena: indirizzo di default (o primo) → delivery mode preferita → pagamento di default (o primo); ogni anello invoca la facade e poi verifica lo stato dalla query (feature-libs/checkout/base/components/services/express-checkout.service.ts:L35-L46, feature-libs/checkout/base/components/services/express-checkout.service.ts:L48-L169).
5. NotCheckoutAuthGuard (pagina checkout-login) redirige a home se loggato e al carrello se c'è già un guest cart (feature-libs/checkout/base/components/guards/not-checkout-auth.guard.ts:L29-L44).

3.6 Ingresso in uno step: CheckoutStepsSetGuard

1. Nel costruttore (servizio root) sottoscrive hasDeliveryItems(): se il carrello non ha articoli da spedire disabilita DELIVERY_ADDRESS e DELIVERY_MODE e regola nameMultiLine di PAYMENT_DETAILS/REVIEW_ORDER (feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L49-L70, feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L174-L182).
2. canActivate(route) cerca in steps$ (take(1)) lo step la cui rotta coincide con l'URL; se non lo trova, in dev mode logga Missing step with route ... e redirige a checkout (feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L73-L104).
3. Se lo trova, verifica **solo lo step immediatamente precedente** con isStepSet(steps[currentIndex - 1]) (feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L92-L93).
4. isStepSet dispatcha per step.type[0]; per PAYMENT_DETAILS, se lo step DELIVERY_MODE è disabilitato, chiama setDeliveryMode('pickup') prima di verificare il pagamento (feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L106-L132).
5. Le verifiche filtrano !state.loading e, se il dato manca, restituiscono un UrlTree verso la rotta dello step mancante (feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L134-L172).

3.7 Gli step nei componenti

- **Indirizzo.** ngOnInit carica gli indirizzi utente (se non guest) (feature-libs/checkout/base/components/checkout-delivery-address/checkout-delivery-address.component.ts:L114-L119); selectDefaultAddress

auto-seleziona una sola volta il `defaultAddress` (feature-libs/checkout/base/components/checkout-delivery-address/checkout-delivery-address.component.ts:L313-L330). `setAddress = setDeliveryAddress` seguito (switchMap) da `clearCheckoutDeliveryMode()` (feature-libs/checkout/base/components/checkout-delivery-address/checkout-delivery-address.component.ts:L357-L374); `addAddress = createAndSetAddress` → clear delivery mode → `next()` (feature-libs/checkout/base/components/checkout-delivery-address/checkout-delivery-address.component.ts:L213-L246).

- **Delivery mode.** `supportedDeliveryModes$` in un `tap` imposta sempre una modalità (quella selezionata se ancora nella lista, altrimenti la preferita) chiamando `changeMode`, e nasconde dalla lista il codice `pickup` (feature-libs/checkout/base/components/checkout-delivery-mode/checkout-delivery-mode.component.ts:L79-L100). Il componente ha `composition.inner: ['PickupInStoreDeliveryModeComponent']` (feature-libs/checkout/base/components/checkout-delivery-mode/checkout-delivery-mode.module.ts:L37-L49).
- **Pagamento.** `CheckoutPaymentMethodComponent.ngOnInit` carica i metodi di pagamento utente (se non guest) e memorizza l'indirizzo di consegna come fallback del billing (feature-libs/checkout/base/components/checkout-payment-method/checkout-payment-method.component.ts:L131-L147); `setPaymentDetails` usa `billingAddress ?? this.deliveryAddress`, chiama `createPaymentDetails` e al complete `next()` (feature-libs/checkout/base/components/checkout-payment-method/checkout-payment-method.component.ts:L278-L301). Il form carta emette `billingAddress: null` se "same as delivery" (feature-libs/checkout/base/components/checkout-payment-method/checkout-payment-form/checkout-payment-form.component.ts:L273-L312).
- **SOP (Silent Order Post).** `OccCheckoutPaymentAdapter.createPaymentDetails` fa GET `payment/sop/request`, POST form-urlencoded al `postUrl` del provider, parsing dell'HTML di risposta (primo `<form>`, i suoi `input`), POST `payment/sop/response`, normalizzazione con `PAYMENT_DETAILS_NORMALIZER`; forza `savePaymentInfo = true` (feature-libs/checkout/base/occ/adapters/occ-checkout-payment.adapter.ts:L46-L95, feature-libs/checkout/base/occ/adapters/occ-checkout-payment.adapter.ts:L312-L330). I parametri sono rimappati con le `mappingLabels` (`hybris_card_number`, `hybris_billTo_*`) (feature-libs/checkout/base/occ/adapters/occ-checkout-payment.adapter.ts:L265-L310).
- **Review.** `CheckoutReviewSubmitComponent` raggruppa gli step in "delivery" e "payment" tramite metodi protetti sovrascrivibili (feature-libs/checkout/base/components/checkout-review-submit/checkout-review-submit.component.ts:L101-L110).
- **Place order.** Form `termsAndConditions: [false, Validators.requiredTrue]` (feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L76-L78). `submitForm()` con il toggle `enableCartSlowNetworkResilience` piazza l'ordine solo se `isStable()` è true (feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L124-L142); `launchPlaceOrder()` apre lo spinner `LAUNCH_CALLER.PLACE_ORDER_SPINNER`, chiama `orderFacade.placeOrder(valid)`, al successo naviga a `orderConfirmation`, in errore chiude lo spinner (feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L144-L170). Lato order, `placeOrderCommand` dispatcha `OrderPlacedEvent` con `cartCode: cartId` (feature-libs/order/core/facade/order.service.ts:L26-L54).
- **Guest login.** `CheckoutLoginComponent.onSubmit` chiama `activeCartFacade.addEmail(email)` e, quando il carrello diventa guest, `authRedirectService.redirect()` (feature-libs/checkout/base/components/checkout-login/checkout-login.component.ts:L58-L73).
- **Progress.** Stato step: `DISABLED` se indice > attivo, `SELECTED` se attivo, altrimenti `COMPLETED` (feature-libs/checkout/base/components/checkout-progress/checkout-progress.component.ts:L67-L87).

3.8 Interceptor "Cart not found"

`CheckoutCartInterceptor` legge una sola volta lo stato router e osserva solo gli errori della richiesta; se la rotta semantica inizia (case-insensitive) con `checkout` e l'errore è 400 con `errors[0].type === 'CartError'` e `reason === 'notFound'`, naviga a `cart` e ricarica il carrello indicato in `errors[0].subject` (feature-libs/

checkout/base/root/http-interceptors/checkout-cart.interceptor.ts:L37-L94). È l'unico interceptor del checkout ed è registrato via useExisting (feature-libs/checkout/base/root/http-interceptors/index.ts:L11-L17).

3.9 B2B

1. CheckoutB2BRootModule importa per primo ./model/augmented-types ("Import augmented types first") e ridefinisce i cmsComponents della **stessa** feature checkout (base + CheckoutCostCenterComponent, CheckoutPaymentType) (feature-libs/checkout/b2b/root/checkout-b2b-root.module.ts:L8-L52).
2. L'augmentation aggiunge CheckoutStepType.PAYMENT_TYPE = 'paymentType' sia come tipo (declare module) sia a runtime (assegnazione sull'enum), più costCenter, purchaseOrderNumber, paymentType a CheckoutState (feature-libs/checkout/b2b/root/model/augmented-types.ts:L11-L23). È possibile perché il public_api root esporta CheckoutStepType e CheckoutState nel blocco delimitato dal commento AUGMENTABLE_TYPES_START/END (feature-libs/checkout/base/root/public_api.ts:L14-L17).
3. I default B2B sono 5 step con paymentType (rotta checkout/payment-type) per primo (feature-libs/checkout/b2b/root/config/default-b2b-checkout-config.ts:L13-L51, feature-libs/checkout/b2b/root/config/default-checkout-b2b-routing-config.ts:L9-L15). Poiché deepMerge sostituisce gli array, gli step B2B **rimpiazzano** quelli base, mentre gli oggetti vengono fusi (la dependencies della feature base resta) (core-libs/core/src/config/utils/deep-merge.ts:L7-L9, core-libs/core/src/config/utils/deep-merge.ts:L31-L46).
4. CheckoutB2BComponentsModule (nel chunk lazy) sostituisce CheckoutAuthGuard → CheckoutB2BAuthGuard e CheckoutStepsSetGuard → CheckoutB2BStepsSetGuard con useExisting (feature-libs/checkout/b2b/components/checkout-b2b-components.module.ts:L28-L37); l'override ha effetto grazie a getLastValueSync sull'UnifiedInjector (§3.5).
5. CheckoutB2BAuthGuard richiede inoltre, per utenti con roles, il ruolo B2BUserRole.CUSTOMER, altrimenti warning checkoutB2B.invalid.accountType e redirect home (feature-libs/checkout/b2b/components/guards/checkout-b2b-auth.guard.ts:L51-L88).
6. CheckoutB2BStepsSetGuard disabilita PAYMENT_DETAILS quando il pagamento è ACCOUNT, poi verifica lo step precedente; per DELIVERY_ADDRESS con ACCOUNT richiede indirizzo + cost center, senza ACCOUNT richiede indirizzo e costCenter === undefined (feature-libs/checkout/b2b/components/guards/checkout-b2b-steps-set.guard.ts:L57-L97, feature-libs/checkout/b2b/components/guards/checkout-b2b-steps-set.guard.ts:L139-L177).
7. Componenti: CheckoutPaymentTypeComponent auto-imposta il primo tipo se il selezionato non è disponibile e abilita/disabilita PAYMENT_DETAILS (feature-libs/checkout/b2b/components/checkout-payment-type/checkout-payment-type.component.ts:L85-L130); CheckoutCostCenterComponent è nascosto se non ACCOUNT e imposta il primo cost center attivo se il carrello non ne ha (feature-libs/checkout/b2b/components/checkout-cost-center/checkout-cost-center.component.ts:L44-L88); B2BCheckoutDeliveryAddressComponent con ACCOUNT mostra gli indirizzi del cost center (feature-libs/checkout/b2b/components/checkout-delivery-address/checkout-delivery-address.component.ts:L74-L93).
8. Set di cost center o payment type → reset delivery modes + reset query (feature-libs/checkout/b2b/root/events/checkout-cost-center-event.listener.ts:L26-L38, feature-libs/checkout/b2b/root/events/checkout-payment-type-event.listener.ts:L39-L51). BadCostCenterRequestHandler (registrato come HttpErrorHandler multi) mostra checkoutB2B.invalidCostCenter su 400 con almeno un errore EntityValidationError (scartati prima i NO_LONGER_VALID) e URL il cui path termina con costcenter **e** che contiene il query param costCenterId (feature-libs/checkout/b2b/core/http-interceptors/bad-request/bad-cost-center-request.handler.ts:L50-L63, feature-libs/checkout/b2b/core/http-interceptors/bad-request/bad-cost-center-request.model.ts:L9-L9, feature-libs/checkout/b2b/core/

checkout-b2b-core.module.ts:L14-L26, feature-libs/checkout/b2b/core/http-interceptors/bad-request/bad-cost-center-request.handler.ts:L22-L71).

3.10 Scheduled replenishment

1. `CheckoutScheduledReplenishmentRootModule` ridefinisce ancora i `cmsComponents` di `checkout` = B2B + `CheckoutScheduleReplenishmentOrder` (feature-libs/checkout/scheduled-replenishment/root/checkout-scheduled-replenishment-root.module.ts:L13-L37).
2. `CheckoutReplenishmentFormService` (root) tiene i dati del form (default: daily, 14 giorni, lunedì, data odierna ISO) e `orderType$` (default `PLACE_ORDER`) (feature-libs/checkout/scheduled-replenishment/components/services/checkout-replenishment-form.service.ts:L39-L52), che torna a `PLACE_ORDER` su `CheckoutDeliveryAddressSetEvent`, `CheckoutDeliveryAddressClearedEvent`, `CheckoutDeliveryModeSetEvent`, `CheckoutDeliveryModeClearedEvent`, `CheckoutPaymentDetailsCreatedEvent`, `CheckoutPaymentDetailsSetEvent`, login/logout e save/restore/merge cart; non su `CheckoutDeliveryAddressCreatedEvent`, e non esiste un evento di clear del pagamento (feature-libs/checkout/scheduled-replenishment/components/services/checkout-replenishment-form.service.ts:L58-L78).
3. `CheckoutScheduledReplenishmentPlaceOrderComponent` estende il componente base e sceglie tra `orderFacade.placeOrder` e `scheduledReplenishmentOrderFacade.scheduleReplenishmentOrder(formData, termsChecked)`, navigando a `orderConfirmation` o `replenishmentConfirmation` (feature-libs/checkout/scheduled-replenishment/components/checkout-place-order/checkout-place-order.component.ts:L105-L170); ridefinisce `CheckoutPlaceOrder` nel CMS config (feature-libs/checkout/scheduled-replenishment/components/checkout-place-order/checkout-place-order.module.ts:L35-L42).
4. `ReplenishmentOrderScheduledEvent` → `RemoveCartEvent` + `CheckoutQueryResetEvent` (feature-libs/checkout/scheduled-replenishment/root/events/checkout-scheduled-replenishment-event.listener.ts:L24-L41).

---

5. Estratti di codice reale

5.1 Mapping lazy e root module

feature-libs/checkout/base/root/checkout-root.module.ts:L37-L60

TS

```ts
export function defaultCheckoutComponentsConfig() {
  const config: CmsConfig = {
    featureModules: {
      [CHECKOUT_FEATURE]: {
        cmsComponents: CHECKOUT_BASE_CMS_COMPONENTS,
        dependencies: [CART_BASE_FEATURE],
      },
      // by default core is bundled together with components
      [CHECKOUT_CORE_FEATURE]: CHECKOUT_FEATURE,
    },
  };
  return config;
}

@NgModule({
  imports: [CheckoutEventModule],
  providers: [
    ...interceptors,
    provideDefaultConfig(defaultCheckoutRoutingConfig),
    provideDefaultConfig(defaultCheckoutConfig),
    provideDefaultConfigFactory(defaultCheckoutComponentsConfig),
  ],
})
export class CheckoutRootModule {}
```

5.2 Una facade lazy

feature-libs/checkout/base/root/facade/checkout-delivery-address.facade.ts:L12-L28

TS

```ts
@Injectable({
  providedIn: 'root',
  useFactory: () =>
    facadeFactory({
      facade: CheckoutDeliveryAddressFacade,
      feature: CHECKOUT_CORE_FEATURE,
      methods: [
        'getDeliveryAddressState',
```

```
        'createAndSetAddress',
        'setDeliveryAddress',
        'clearCheckoutDeliveryAddress',
      ],
      // TODO:#deprecation-checkout - remove once we remove ngrx
      async: true,
    }),
})
export abstract class CheckoutDeliveryAddressFacade {
```

5.3 La query centrale e le precondizioni

feature-libs/checkout/base/core/facade/checkout-query.service.ts:L32-L54

```ts
  protected getCheckoutQueryReloadEvents(): QueryNotifier[] {
    return [CheckoutQueryReloadEvent];
  }
  /**
   * Returns the reset events for the checkout query.
   */
  protected getCheckoutQueryResetEvents(): QueryNotifier[] {
    return [CheckoutQueryResetEvent];
  }

  protected checkoutQuery$: Query<CheckoutState | undefined> =
    this.queryService.create<CheckoutState | undefined>(
      () =>
        this.checkoutPreconditions().pipe(
          switchMap(([userId, cartId]) =>
            this.checkoutConnector.getCheckoutDetails(userId, cartId)
          )
        ),
      {
        reloadOn: this.getCheckoutQueryReloadEvents(),
        resetOn: this.getCheckoutQueryResetEvents(),
      }
    );
```

feature-libs/checkout/base/core/facade/checkout-query.service.ts:L66-L84

```ts
  protected checkoutPreconditions(): Observable<[string, string]> {
    return combineLatest([
      this.userIdService.takeUserId(),
      this.activeCartFacade.takeActiveCartId(),
      this.activeCartFacade.isGuestCart(),
    ]).pipe(
      take(1),
      map(([userId, cartId, isGuestCart]) => {
```

```
      if (
        !userId ||
        !cartId ||
        (userId === OCC_USER_ID_ANONYMOUS && !isGuestCart)
      ) {
        throw new Error('Checkout conditions not met');
      }
      return [userId, cartId];
    })
  );
}
```

5.4 Un command con evento e una proiezione

feature-libs/checkout/base/core/facade/checkout-delivery-address.service.ts:L66-L94

```ts
protected setDeliveryAddressCommand: Command<Address, unknown> =
  this.commandService.create<Address>(
    (address) =>
      this.checkoutPreconditions().pipe(
        switchMap(([userId, cartId]) => {
          const addressId = address.id;
          if (!addressId) {
            throw new Error('Checkout conditions not met');
          }
          return this.checkoutDeliveryAddressConnector
            .setAddress(userId, cartId, addressId)
            .pipe(
              tap(() => {
                this.eventService.dispatch(
                  {
                    userId,
                    cartId,
                    address,
                  },
                  CheckoutDeliveryAddressSetEvent
                );
              })
            );
        })
      ),
    {
      strategy: CommandStrategy.CancelPrevious,
    }
  );
```

feature-libs/checkout/base/core/facade/checkout-delivery-address.service.ts:L153-L160

```ts
getDeliveryAddressState(): Observable<QueryState<Address | undefined>> {
  return this.checkoutQueryFacade.getCheckoutDetailsState().pipe(
    map((state) => ({
      ...state,
      data: state.data?.deliveryAddress,
    }))
  );
}
```

5.5 Listener che invalida la query

feature-libs/checkout/base/root/events/checkout-delivery-address-event.listener.ts:L109-L122

```ts
protected onDeliveryAddressSet(): void {
  this.subscriptions.add(
    this.eventService
      .get(CheckoutDeliveryAddressSetEvent)
      .subscribe(({ userId, cartId }) => {
        this.eventService.dispatch(
          { userId, cartId },
          CheckoutSupportedDeliveryModesQueryResetEvent
        );

        this.eventService.dispatch({}, CheckoutQueryResetEvent);
      })
  );
}
```

5.6 Step e flow

feature-libs/checkout/base/components/services/checkout-step.service.ts:L88-L100

```ts
resetSteps(): void {
  let steps = this.checkoutConfig.checkout?.steps ?? [];

  if (this.checkoutFlowOrchestratorService) {
    steps =
      this.checkoutFlowOrchestratorService.getCheckoutFlow()?.steps ?? [];
  }

  this.allSteps = steps
    .filter((step) => !step.disabled)
    .map((checkoutStep) => Object.assign({}, checkoutStep));
  this.steps$.next(this.allSteps);
}
```

feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L20-L44

```ts
constructor() {
  this.getPaymentProvider().subscribe((paymentProvider) => {
    this.paymentProviderName = paymentProvider;
  });
}

protected paymentProviderName: string | undefined = undefined;

getPaymentProvider(): Observable<string | undefined> {
  return this.baseSiteService.get().pipe(
    take(1),
    map((baseSite) => baseSite?.baseStore?.paymentProvider)
  );
}

getCheckoutFlow(): CheckoutFlow | undefined {
  if (this.paymentProviderName) {
    const flow =
      this.checkoutConfig.checkout?.flows?.[this.paymentProviderName];
    if (flow) {
      return flow;
    }
  }
  return this.checkoutConfig.checkout;
}
```

5.7 `CheckoutGuard` ed express checkout

feature-libs/checkout/base/components/guards/checkout.guard.ts:L41-L70

```ts
canActivate(): Observable<GuardResult> {
  const expressCheckout$ = this.expressCheckoutService
    .trySetDefaultCheckoutDetails()
    .pipe(
      switchMap((expressCheckoutPossible) => {
        const reviewOrderRoute =
          this.checkoutStepService.getCheckoutStepRoute(
            CheckoutStepType.REVIEW_ORDER
          );
        return expressCheckoutPossible && reviewOrderRoute
          ? of(
              this.router.parseUrl(
                this.routingConfigService.getRouteConfig(reviewOrderRoute)
                  ?.paths?.[0] as string
              )
            )
          : this.firstStep$;
      })
```

```
    );

  return this.activeCartFacade
    .isGuestCart()
    .pipe(
      switchMap((isGuestCart) =>
        this.checkoutConfigService.isExpressCheckout() && !isGuestCart
          ? expressCheckout$
          : this.firstStep$
      )
    );
}
```

5.8 Il guard degli step (cuore)

feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L106-L132

```ts
protected isStepSet(step: CheckoutStep): Observable<GuardResult> {
  if (step && !step.disabled) {
    switch (step.type[0]) {
      case CheckoutStepType.DELIVERY_ADDRESS: {
        return this.isDeliveryAddress(step);
      }
      case CheckoutStepType.DELIVERY_MODE: {
        return this.isDeliveryModeSet(step);
      }
      case CheckoutStepType.PAYMENT_DETAILS: {
        if (
          this.checkoutStepService.getCheckoutStep(
            CheckoutStepType.DELIVERY_MODE
          )?.disabled
        ) {
          this.checkoutDeliveryModesFacade.setDeliveryMode('pickup');
        }

        return this.isPaymentDetailsSet(step);
      }
      case CheckoutStepType.REVIEW_ORDER: {
        break;
      }
    }
  }
  return of(true);
}
```

5.9 Interceptor

feature-libs/checkout/base/root/http-interceptors/checkout-cart.interceptor.ts:L37-L61

```ts
    return this.routingService.getRouterState().pipe(
      take(1),
      switchMap((state: RouterState) => {
        return next.handle(request).pipe(
          tap({
            error: (response) => {
              if (
                response instanceof HttpErrorResponse &&
                this.isUserInCheckoutRoute(state.state?.semanticRoute)
              ) {
                if (this.isCartNotFoundError(response)) {
                  this.routingService.go({ cxRoute: 'cart' });

                  const cartCode = this.getCartIdFromError(response);
                  if (cartCode) {
                    this.multiCartFacade.reloadCart(cartCode);
                  }
                }
              }
            },
          })
        );
      })
    );
  }
```

5.10 SOP nell'adapter OCC

feature-libs/checkout/base/occ/adapters/occ-checkout-payment.adapter.ts:L55-L94

```ts
    return this.getProviderSubInfo(userId, cartId).pipe(
      map((data) => {
        const labelsMap = this.convertToMap(data.mappingLabels.entry) as {
          [key: string]: string;
        };
        return {
          url: data.postUrl,
          parameters: this.getParamsForPaymentProvider(
            paymentDetails,
            data.parameters.entry,
            labelsMap
          ),
          mappingLabels: labelsMap,
        };
      }),
      mergeMap((sub) =>
        // create a subscription directly with payment provider
        this.createSubWithProvider(sub.url, sub.parameters).pipe(
```

```
        map((response) => this.extractPaymentDetailsFromHtml(response)),
        mergeMap((fromPaymentProvider) => {
          fromPaymentProvider['defaultPayment'] =
            paymentDetails.defaultPayment ?? false;
          fromPaymentProvider['savePaymentInfo'] = true;
          return this.createDetailsWithParameters(
            userId,
            cartId,
            fromPaymentProvider
          ).pipe(
            catchError((error) => {
              throw tryNormalizeHttpError(error, this.logger);
            }),
            backOff({
              shouldRetry: isJaloError,
            }),
            this.converter.pipeable(PAYMENT_DETAILS_NORMALIZER)
          );
        })
      )
    )
  );
```

5.11 Place order con gate di stabilità

feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L124-L142

```ts
  submitForm(): void {
    if (!this.checkoutSubmitForm.valid) {
      this.checkoutSubmitForm.markAllAsTouched();
      return;
    }
    if (!this.featureToggles.enableCartSlowNetworkResilience) {
      this.launchPlaceOrder();
      return;
    }
    this.activeCartFacade
      .isStable()
      .pipe(take(1))
      .subscribe((isStable) => {
        if (!isStable) {
          return;
        }
        this.launchPlaceOrder();
      });
  }
```

5.12 B2B: augmentation e override dei guard

feature-libs/checkout/b2b/root/model/augmented-types.ts:L11-L23

```ts
declare module '@spartacus/checkout/base/root' {
  enum CheckoutStepType {
    PAYMENT_TYPE = 'paymentType',
  }

  interface CheckoutState {
    costCenter?: CostCenter;
    purchaseOrderNumber?: string;
    paymentType?: PaymentType;
  }
}

(CheckoutStepType as any)['PAYMENT_TYPE'] = 'paymentType';
```

feature-libs/checkout/b2b/components/checkout-b2b-components.module.ts:L28-L37

```ts
  providers: [
    {
      provide: CheckoutAuthGuard,
      useExisting: CheckoutB2BAuthGuard,
    },
    {
      provide: CheckoutStepsSetGuard,
      useExisting: CheckoutB2BStepsSetGuard,
    },
  ],
```

getCheckoutDetails	users/${userId}/carts/${cartId}?fields=deliveryAddress(FULL),deliveryMode(FULL),paymentInfo(FULL)	OccCheckoutAdapter
setBillingAddress	.../addresses/billing	PUT con indirizzo nel body (feature-libs/checkout/base/occ/adapters/occ-checkout-billing-address.adapter.ts:L22-L55)

Esempio di configurazione applicativa (il frammento `provideConfig({ checkout: { guest: true } })` è quello reale dell'app demo, projects/storefrontapp/src/app/spartacus/features/checkout/checkout-feature.module.ts:L99-L103). Per un flow per payment provider la forma attesa è `checkout.flows['<nome provider>'] = { steps: [...], express, guest, ... }` secondo l'interfaccia `CheckoutFlow` (feature-libs/checkout/base/root/model/checkout-flow.model.ts:L10-L31); nessun default ne definisce uno in questa lib.

---

7. Commenti e note notevoli dal sorgente

- `// TODO:#deprecation-checkout - remove once we remove ngrx` sull'`async: true` delle facade: il `delay(0)` è un residuo dell'era NgRx (feature-libs/checkout/base/root/facade/checkout-delivery-address.facade.ts:L24-L25).
- `// by default core is bundled together with components`: spiega l'alias `checkoutCore → checkout`; separare core e componenti in chunk diversi richiede di ridefinire quella chiave (feature-libs/checkout/base/root/checkout-root.module.ts:L44-L45).
- JSDoc dell'interceptor: "he is redirected to checkout and the cart is reloaded" — ma il codice naviga a `cart` (feature-libs/checkout/base/root/http-interceptors/checkout-cart.interceptor.ts:L20-L25 vs feature-libs/checkout/base/root/http-interceptors/checkout-cart.interceptor.ts:L48-L48).
- "we want to LL the checkout (if not already loaded), in order to clear the checkout data that's potentially set on the back-end": il listener usa la facade proprio per forzare il lazy loading (feature-libs/checkout/base/root/events/checkout-delivery-address-event.listener.ts:L74-L74).
- "As we know the cart is not anonymous (precondition checked), we can safely use the cartId, which is actually the cart.code." (feature-libs/checkout/base/core/facade/checkout-delivery-modes.service.ts:L104-L107; stesso commento in feature-libs/order/core/facade/order.service.ts:L38-L41).
- JSDoc di `PLACE_ORDER_GATE_SAFETY_VALVE_MS` e `isCartUpdating$`: il bottone è disabilitato finché il carrello non è stabile, per evitare il "phantom cart" (CXSPA-10582), con valvola di sicurezza di 10 secondi (feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L47-L53, feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L83-L100). Attenzione: la promessa del JSDoc ("cannot lock the user out of placing the order") vale solo per il bottone. La valvola agisce su `isCartUpdating$`, cioè sul `[disabled]`; `submitForm()` ricontrolla `isStable()` con `take(1)` ed esce in silenzio se è `false` (feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L133-L141, feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.html:L36-L40). Inoltre il `timer` è nell'inizializzatore del campo: i 10 s partono dalla sottoscrizione di `isCartUpdating$` (render del componente), non dal click.
- `TODO:#9574 - we should be able to remove the spread of CHECKOUT_BASE_CMS_COMPONENTS` in B2B e replenishment: conseguenza della sostituzione degli array nel merge (feature-libs/checkout/b2b/root/

checkout-b2b-root.module.ts:L24-L28, feature-libs/checkout/scheduled-replenishment/root/checkout-scheduled-replenishment-root.module.ts:L14-L18).

- `// Import augmented types first` nel root B2B: l'assegnazione runtime su `CheckoutStepType` deve avvenire prima che le config B2B usino `PAYMENT_TYPE` (feature-libs/checkout/b2b/root/checkout-b2b-root.module.ts:L8-L9).
- `// TODO:#checkout - handle breaking changes in schematics` sul parametro `UnifiedInjector` di `CmsGuardsService`, introdotto proprio per gli override lazy dei guard (core-libs/storefront/cms-structure/services/cms-guards.service.ts:L25-L26).
- TODO CXSPA-1276: `verifyAddress()` del billing form non è usato (feature-libs/checkout/base/components/checkout-billing-address/checkout-billing-address-form.component.ts:L165-L178).
- Deprecazioni: `getCardRole()` `@deprecated since 221121.8` (feature-libs/checkout/base/components/checkout-delivery-address/checkout-delivery-address.component.ts:L388-L398); `useExtractedBillingAddressComponent` obsoleto dal 2211.42 (feature-libs/checkout/base/components/checkout-payment-method/checkout-payment-form/checkout-payment-form.component.ts:L172-L175).

8. Extension point

EXTENSION POINT	COME	RIFERIMENTO	RICETTA
Ordine/insieme degli step	`provideConfig({ checkout: { steps: [...] } })` ridefinendo **l'intero** array	feature-libs/checkout/base/root/config/default-checkout-config.ts:L10-L42, core-libs/core/src/config/utils/deep-merge.ts:L31-L46	Parte III, cap. 53
Nuovo tipo di step	Augmentation di `CheckoutStepType` (tipo + assegnazione runtime, come in B2B) + rotta semantica + componente CMS	feature-libs/checkout/b2b/root/model/augmented-types.ts:L11-L23, feature-libs/checkout/base/root/public_api.ts:L14-L17	Parte III, cap. 53
Flow per payment provider	`checkout.flows[provider]`	feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L35-L44	Parte III, cap. 53
Stato aggiuntivo nel checkout	Augmentation di `CheckoutState` + override endpoint `getCheckoutDetails` (`fields`)	feature-libs/checkout/b2b/root/model/augmented-types.ts:L16-L20, feature-libs/checkout/b2b/occ/config/default-occ-checkout-b2b-config.ts:L11-L29	Parte III, cap. 52

EXTENSION POINT	COME	RIFERIMENTO	RICETTA
Sostituire/estendere un guard	`{ provide: CheckoutStepsSetGuard, useExisting: MyGuard }` nel modulo (anche lazy); metodi `protected isStepSet/is*Set` sovrascrivibili	feature-libs/checkout/b2b/components/checkout-b2b-components.module.ts:L28-L37, feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L106-L172	Parte III, cap. 53
Sostituire un componente di step	`cmsComponents: { CheckoutDeliveryAddress: { component: ... } }` (come fa il B2B)	feature-libs/checkout/b2b/components/checkout-delivery-address/checkout-delivery-address.module.ts:L38-L44	Parte III, cap. 51
Raggruppamento review	Override di `getCheckoutDeliverySteps`/`getCheckoutPaymentSteps`	feature-libs/checkout/base/components/checkout-review-submit/checkout-review-submit.component.ts:L101-L110	Parte III, cap. 51
Contenuto extra nel delivery mode	Outlet `CartOutlets.DELIVERY_MODE`	feature-libs/checkout/base/components/checkout-delivery-mode/checkout-delivery-mode.component.html:L55-L56	Parte III, cap. 51
Eventi di invalidazione della query	Sottoclasse di `CheckoutQueryService` con `getCheckoutQueryReloadEvents()`/`getCheckoutQueryResetEvents()`	feature-libs/checkout/base/core/facade/checkout-query.service.ts:L32-L40	Parte III, cap. 53
Reagire ai passaggi del checkout	`eventService.get(CheckoutDeliveryModeSetEvent)` ecc.	feature-libs/checkout/base/root/events/checkout.events.ts:L12-L203	Parte III, cap. 50
Backend diverso da OCC	Fornire i 5 adapter astratti (`CheckoutAdapter`, `CheckoutDeliveryAddressAdapter`, `CheckoutDeliveryModesAdapter`, `CheckoutPaymentAdapter`, `CheckoutBillingAddressAdapter`)	feature-libs/checkout/base/occ/checkout-occ.module.ts:L24-L50	Parte III, cap. 52

EXTENSION POINT	COME	RIFERIMENTO	RICETTA
Endpoint / converter	Override `backend.occ.endpoints.*`; converter su `CHECKOUT_NORMALIZER`, `DELIVERY_MODE_NORMALIZER`, `PAYMENT_DETAILS_SERIALIZER`, `PAYMENT_CARD_TYPE_NORMALIZER`, `PAYMENT_DETAILS_NORMALIZER`	`feature-libs/checkout/base/core/connectors/checkout/converters.ts:L11-L13`, `feature-libs/checkout/base/core/connectors/checkout-delivery-modes/converters.ts:L11-L13` (usato in `feature-libs/checkout/base/occ/adapters/occ-checkout-delivery-modes.adapter.ts:L83-L83`), `feature-libs/checkout/base/core/connectors/checkout-payment/converters.ts:L10-L16`, `core-libs/core/src/checkout/connectors/payment/converters.ts:L11-L13`	Parte III, cap. 52
Meta della pagina checkout	`CheckoutPageMetaResolver` registrato come `PageMetaResolver` multi	`feature-libs/checkout/base/core/checkout-core.module.ts:L17-L33`, `feature-libs/checkout/base/core/services/checkout-page-meta.resolver.ts:L40-L76`	Parte III, cap. 52
Separare core dai componenti	Ridefinire `featureModules.checkoutCore` come modulo autonomo	`feature-libs/checkout/base/root/checkout-root.module.ts:L44-L45`	Parte III, cap. 53

Simboli non pubblici (da non usare come API stabile, vedi Parte III, cap. 54): `CheckoutCartInterceptor` (`http-interceptors` non è esportato dal public_api root, `feature-libs/checkout/base/root/public_api.ts:L7-L17`), `defaultPlaceOrderSpinnerLayoutConfig` (`feature-libs/checkout/base/components/public_api.ts:L22-L23` esporta solo component e module del place order), `BadCostCenterRequestHandler` (`feature-libs/checkout/b2b/core/public_api.ts:L7-L9` esporta solo module, `connectors/index` e `facade/index`). Nessun altro `index.ts`/`public_api.ts` della lib li esporta.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. **Gli array di config si sostituiscono.** Chi ridefinisce `checkout.steps` deve ridefinire tutta la lista; in B2B gli step B2B rimpiazzano quelli base, e i `cmsComponents` B2B devono ri-spalmare la lista base (`core-libs/core/src/config/utils/deep-merge.ts:L7-L9`, `core-libs/core/src/config/utils/deep-merge.ts:L38-L45`, `feature-libs/checkout/b2b/root/checkout-b2b-root.module.ts:L23-L31`). Gli oggetti invece si fondono: la `dependencies` della feature base sopravvive alla ridefinizione B2B (`feature-libs/checkout/b2b/root/checkout-b2b-root.module.ts:L33-L42`).
2. **Il config "puro" non è mai letto direttamente.** `CheckoutFlowOrchestratorService` è root, quindi `if (this.checkoutFlowOrchestratorService)` è sempre vero e tutto passa da `getCheckoutFlow()` (`feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L13-L15`, `feature-libs/checkout/base/components/services/checkout-step.service.ts:L91-L94`).

3. **Race sul payment provider.** `paymentProviderName` è valorizzato in una subscribe; `CheckoutConfigService.checkoutFlow` e `CheckoutStepService.resetSteps()` leggono il flow una sola volta alla costruzione: se il base site non è ancora disponibile, si usa il flow di default (feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L20-L26, feature-libs/checkout/base/components/services/checkout-config.service.ts:L28-L29). Il meccanismo è confermato dal codice: `BaseSiteService.get()` filtra sia il site attivo (`filter((active) => Boolean(active))`) sia la lista dei site (`filter(isNotNullable)`), quindi finché i site non sono caricati la `take(1)` dell'orchestratore non emette e `paymentProviderName` resta `undefined` (core-libs/core/src/site-context/facade/base-site.service.ts:L31-L51, core-libs/core/src/site-context/facade/base-site.service.ts:L56-L70). DA VERIFICARE a runtime solo se, in pratica, il checkout viene istanziato prima del caricamento dei site.
4. **Solo lo step precedente è verificato.** Navigando direttamente al review, `CheckoutStepsSetGuard` controlla solo il pagamento, non indirizzo e delivery mode (feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L92-L93). Inoltre il guard è sui componenti progress, non sugli step: una pagina di step senza `CheckoutProgress` non è protetta (feature-libs/checkout/base/components/checkout-progress/checkout-progress.module.ts:L33-L40).
5. **Effetti collaterali nei guard.** `setDeliveryMode('pickup')` è fire-and-forget e funziona solo perché la chiamata facade e `Command.execute` sono eager (feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L121-L121, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L75-L82). Il guard B2B non replica questa logica (feature-libs/checkout/b2b/components/guards/checkout-b2b-steps-set.guard.ts:L114-L116).
6. **Il guard degli step muta lo stato globale.** La subscription su `hasDeliveryItems()` vive quanto l'app (servizio root) e muta `nameMultiLine` sugli oggetti di `allSteps` (feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L49-L70, feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L174-L182).
7. **Precondizioni fallite = "step non impostato".** Se le precondizioni lanciano, la query va in errore con `data: undefined`; i guard filtrano solo `!loading` e quindi redirigono allo step (core-libs/core/src/util/command-query/query.service.ts:L98-L101, feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L134-L145).
8. **Delivery mode: un PUT a ogni emissione.** Il componente chiama `changeMode` a ogni emissione di `supportedDeliveryModes$`, anche se il codice è già selezionato (feature-libs/checkout/base/components/checkout-delivery-mode/checkout-delivery-mode.component.ts:L84-L96).
9. **Preferenze delivery mode.** `compareDeliveryCost` restituisce 0 se uno dei costi è 0 (falsy), quindi le modalità gratuite non vengono ordinate; `FREE` guarda solo `deliveryModes[0]`; `findMatchingDeliveryMode` accede a `deliveryModes[0]` senza controllare la lunghezza; `getPreferredDeliveryMode` ordina **in place** l'array ricevuto (feature-libs/checkout/base/components/services/checkout-config.service.ts:L39-L104).
10. `getCheckoutStepIndex` **può restituire** `-1`, e `getCheckoutStep` legge allora `allSteps[-1]` (undefined) (feature-libs/checkout/base/components/services/checkout-step.service.ts:L115-L120, feature-libs/checkout/base/components/services/checkout-step.service.ts:L194-L203).
11. **SOP in SSR.** `DOMParser` è istanziato solo se esiste, ma `extractPaymentDetailsFromHtml` lo usa senza guard (feature-libs/checkout/base/occ/adapters/occ-checkout-payment.adapter.ts:L39-L44, feature-libs/checkout/base/occ/adapters/occ-checkout-payment.adapter.ts:L315-L315). E `street1` è `line1 + ' ' + line2`: con `line2` undefined diventa la stringa `"... undefined"` (feature-libs/checkout/base/occ/adapters/occ-checkout-payment.adapter.ts:L295-L298).
12. **Billing address senza eventi.** Il set del billing address non dispatcha eventi né resetta la query (feature-libs/checkout/base/core/facade/checkout-billing-address.service.ts:L36-L53).
13. **Strategie diverse.** `deletePaymentMethodCommand` usa `Queue`, tutti gli altri `CancelPrevious` (feature-libs/checkout/base/core/facade/checkout-payment.service.ts:L112-L123).

14. **Card types senza filtro** `loading`. `getPaymentCardTypes()` emette `[]` iniziale, `getSupportedDeliveryModes()` invece attende `!loading` (feature-libs/checkout/base/core/facade/checkout-payment.service.ts:L162-L166, feature-libs/checkout/base/core/facade/checkout-delivery-modes.service.ts:L173-L178).
15. **Interceptor: JSDoc fuorviante** (vedi §7) e attivo su qualunque rotta semantica che *inizi* con `checkout` (feature-libs/checkout/base/root/http-interceptors/checkout-cart.interceptor.ts:L75-L77).
16. **B2B senza** `async`. Le facade B2B non hanno `async: true` a differenza delle base (feature-libs/checkout/b2b/root/facade/checkout-cost-center.facade.ts:L15-L20). `CheckoutCostCenterComponent` accede a `costCenters[0].code` senza controllare la lista e non sottoscrive il risultato del set (feature-libs/checkout/b2b/components/checkout-cost-center/checkout-cost-center.component.ts:L74-L88).
17. **Replenishment.** `replenishmentStartDate` è calcolato una volta alla costruzione del servizio root con `toISOString()` (UTC) (feature-libs/checkout/scheduled-replenishment/components/services/checkout-replenishment-form.service.ts:L39-L46); il place order esteso non chiama `super.ngOnInit()` (feature-libs/checkout/scheduled-replenishment/components/checkout-place-order/checkout-place-order.component.ts:L136-L155).
18. **DOM fuori da Angular.** `CheckoutReviewOverviewComponent` sposta nodi DOM con `requestAnimationFrame` (feature-libs/checkout/base/components/checkout-review/checkout-review-overview/checkout-review-overview.component.ts:L61-L72); delivery mode e payment form usano `document` globale (feature-libs/checkout/base/components/checkout-delivery-mode/checkout-delivery-mode.component.ts:L187-L191).
19. `@Optional()` **inutile** su proprietà inizializzate con `inject()` (feature-libs/checkout/base/components/checkout-delivery-address/checkout-delivery-address.component.ts:L100-L101).

---

10. Come fare debug

- **Il chunk non si carica / "Feature checkoutCore is not configured properly".** Il proxy lancia questo errore se la feature non è configurata (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L43-L47): verificare che `CheckoutRootModule` sia importato e che `featureModules.checkout.module` sia fornito dall'app (projects/storefrontapp/src/app/spartacus/features/checkout/checkout-feature.module.ts:L41-L87).
- **Stato del checkout.** Non c'è uno slice NgRx da ispezionare: nella scheda Network cercare il GET con `fields=deliveryAddress(FULL),deliveryMode(FULL),paymentInfo(FULL)` (feature-libs/checkout/base/occ/config/default-occ-checkout-config.ts:L29-L30); ogni reset della query provoca un nuovo GET se qualcuno è sottoscritto (core-libs/core/src/util/command-query/query.service.ts:L117-L133).
- **Tracciare gli eventi.** In un componente o `APP_INITIALIZER` di debug, `inject(EventService).get(CheckoutEvent)` riceve tutta la famiglia (feature-libs/checkout/base/root/events/checkout.events.ts:L32-L48); `CheckoutQueryResetEvent` e `CheckoutQueryReloadEvent` vanno ascoltati a parte perché estendono `CxEvent` direttamente (feature-libs/checkout/base/root/events/checkout.events.ts:L12-L203).
- **"Checkout conditions not met".** Viene dalle precondizioni (utente anonimo senza guest cart, carrello mancante) o da `address.id`/`paymentDetails.id` assenti (feature-libs/checkout/base/core/facade/checkout-query.service.ts:L66-L84, feature-libs/checkout/base/core/facade/checkout-delivery-address.service.ts:L71-L74), o da un billing address vuoto/assente passato a `setBillingAddress` (feature-libs/checkout/base/core/facade/checkout-billing-address.service.ts:L40-L42).
- **Redirect inattesi tra step.** Cercare in console il warning dev-mode `Missing step with route ...` (feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L95-L99); verificare quale step è disabilitato (`steps$`), quale guard è effettivamente attivo (in B2B gli override `useExisting`, feature-libs/checkout/b2b/components/checkout-b2b-components.module.ts:L28-L37) e lo stato della query (errore = step mancante, §9.7).

- **Flow sbagliato.** Controllare `baseSite.baseStore.paymentProvider` e la chiave in `checkout.flows` (feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L28-L44).
- **Bottone Place Order disabilitato.** Con `enableCartSlowNetworkResilience` il bottone è disabilitato mentre `isStable()` è `false`, al massimo per 10 s dalla sottoscrizione di `isCartUpdating$` (cioè dal render del componente) (feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L94-L100). Scaduta la valvola il bottone torna attivo, ma `submitForm()` ricontrolla `isStable()` e, se è ancora `false`, esce senza piazzare l'ordine e senza feedback (feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L133-L141). La valvola sblocca quindi solo il bottone, non il place order. Stesso schema nel place order replenishment (feature-libs/checkout/scheduled-replenishment/components/checkout-place-order/checkout-place-order.component.ts:L94-L102).
- **Test.** La lib usa Vitest (jsdom, `pool: 'forks'`) (feature-libs/checkout/vitest.config.ts:L16-L66): `nx test-vitest checkout` o `npx vitest run --config feature-libs/checkout/vitest.config.ts <spec>` (comandi da `.claude/CLAUDE.md`; il nome progetto Nx `checkout` e il target `test-vitest` sono in feature-libs/checkout/project.json:L2-L2 e feature-libs/checkout/project.json:L20-L20).

---

11. Domande di autoverifica

1. **Perché un listener può far scaricare il chunk del checkout?** Perché inietta una facade proxy (`facadeFactory` con feature `checkoutCore`, alias di `checkout`) e la chiamata a un metodo risolve la feature e la carica; la chiamata è eager. — feature-libs/checkout/base/root/checkout-root.module.ts:L44-L45, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L38-L92, feature-libs/checkout/base/root/events/checkout-delivery-address-event.listener.ts:L74-L75
2. **Dove si trova l'indirizzo di consegna selezionato nel client?** Non in uno store: è la proiezione `state.data?.deliveryAddress` dell'unica query `checkoutQuery$`, caricata da `getCheckoutDetails`. — feature-libs/checkout/base/core/facade/checkout-delivery-address.service.ts:L153-L160, feature-libs/checkout/base/core/facade/checkout-query.service.ts:L42-L54
3. **Cosa succede dopo un `setDeliveryAddress` riuscito?** Evento `CheckoutDeliveryAddressSetEvent` → reset delivery modes supportate (→ `LoadCartEvent`) e reset della query; il componente inoltre cancella la delivery mode. — feature-libs/checkout/base/core/facade/checkout-delivery-address.service.ts:L66-L94, feature-libs/checkout/base/root/events/checkout-delivery-address-event.listener.ts:L109-L122, feature-libs/checkout/base/components/checkout-delivery-address/checkout-delivery-address.component.ts:L357-L374
4. **Aggiungo uno step con `provideConfig({ checkout: { steps: [nuovo] } })`: cosa ottengo?** Un checkout con il solo step nuovo, perché `deepMerge` sostituisce gli array: va ridefinita l'intera lista. — core-libs/core/src/config/utils/deep-merge.ts:L31-L46
5. **Perché in B2B il guard `CheckoutStepsSetGuard` viene sostituito anche se è dichiarato nel CMS config base?** `CmsGuardsService` risolve i guard con `getLastValueSync(unifiedInjector.get(...))`, cioè dall'ultimo injector (anche lazy) che fornisce il token; il modulo B2B fornisce `useExisting: CheckoutB2BStepsSetGuard`. — core-libs/storefront/cms-structure/services/cms-guards.service.ts:L41-L46, feature-libs/checkout/b2b/components/checkout-b2b-components.module.ts:L28-L37
6. **Un utente arriva direttamente al review order senza delivery mode ma con un pagamento: il guard lo blocca?** No: `CheckoutStepsSetGuard` verifica solo lo step immediatamente precedente (payment details). — feature-libs/checkout/base/components/guards/checkout-steps-set.guard.ts:L92-L93
7. **Quando il `CheckoutGuard` porta direttamente al review?** Se `isExpressCheckout()` è vero, il carrello non è guest e `ExpressCheckoutService` riesce a impostare indirizzo, delivery mode e pagamento di default. —

feature-libs/checkout/base/components/guards/checkout.guard.ts:L41-L70, feature-libs/checkout/base/components/services/express-checkout.service.ts:L48-L175

8. **Chi piazza l'ordine e come il checkout lo viene a sapere?** `OrderFacade.placeOrder` della lib order; `OrderService` dispatcha `OrderPlacedEvent`, a cui il checkout reagisce con `RemoveCartEvent` e reset della query. — feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L144-L166, feature-libs/order/core/facade/order.service.ts:L26-L54, feature-libs/checkout/base/root/events/checkout-place-order-event.listener.ts:L24-L41
9. **Come fa il B2B ad aggiungere `PAYMENT_TYPE` a un enum di un'altra libreria?** Con `declare module '@spartacus/checkout/base/root'` per il tipo e con un'assegnazione runtime sull'oggetto enum, importata per prima nel root module. — feature-libs/checkout/b2b/root/model/augmented-types.ts:L11-L23, feature-libs/checkout/b2b/root/checkout-b2b-root.module.ts:L8-L9
10. **Cosa fa il checkout se una richiesta restituisce "Cart not found" durante uno step?** L'interceptor, se la rotta semantica inizia con `checkout` e l'errore è 400 `CartError/notFound`, naviga al carrello e ricarica il carrello indicato in `subject`. — feature-libs/checkout/base/root/http-interceptors/checkout-cart.interceptor.ts:L37-L94

Prerequisiti consigliati: 12 — Feature module e lazy loading in Spartacus, 19 — State management, 20 — Facade, command & query, eventi, 21 — Livello OCC, 14 — Routing. Collegati: 26 — Checkout (chi chiama il place order), 25 — Carrello (reorder e rimozione del carrello), 16 — CMS rendering (guard e `providers` dei componenti CMS), 17 — Outlet, 18 — Layout, breakpoint, launch dialog, 28 — B2B organization (endpoint `orgUsers`).

1. A cosa serve e perché esiste

La libreria `@spartacus/order` copre tutto ciò che accade **dopo** (e nell'istante in cui) il carrello diventa un ordine:

- il **place order** e la pagina di conferma (`OrderFacade`);
- la **storia ordini** e il **dettaglio ordine** in "My Account", con il tracking delle spedizioni (`OrderHistoryFacade`);
- la **cancellazione** e il **reso** (return request), con le relative liste e dettagli (`OrderReturnRequestFacade`);
- gli **ordini ricorrenti** (scheduled replenishment) (`ScheduledReplenishmentOrderFacade`, `ReplenishmentOrderHistoryFacade`);
- il **reorder** (ricrea un carrello da un ordine) (`ReorderOrderFacade`);
- gli **allegati** dell'ordine (`OrderAttachmentsFacade`);
- due estensioni "laterali": il **document flow** (`@spartacus/order/document-flow`, documenti successivi SAP) e le **fatture PDF** (libreria separata `@spartacus/pdf-invoices`).

Il punto di ingresso pesante è `OrderModule`, che importa nell'ordine core, OCC e componenti (`feature-libs/order/order.module.ts:L12-L15`). Come per le altre feature lib (vedi capitolo 12) esiste un livello `root` eager — configurazione di default, rotte, facade astratte, eventi, token — e un livello lazy caricato alla prima necessità.

Tre scelte progettuali caratterizzano la libreria e ritornano in tutto il capitolo:

1. **Due modelli di stato convivono.** Il place order, la schedulazione di un replenishment, il reorder e gli allegati usano il pattern *Command* o chiamate dirette al connector, senza NgRx: l'ordine appena piazzato vive in un `BehaviorSubject` (`feature-libs/order/core/facade/order.service.ts:L22-L24`). Storia ordini, dettaglio, resi, replenishment e tracking usano invece uno store NgRx di feature `order` con 9 slice (6 loader, 2 entity loader e lo stato semplice `consignmentTracking`) (`feature-libs/order/core/store/order-state.ts:L37-L51`, `feature-libs/order/core/store/reducers/index.ts:L60-L60`).
2. **I componenti di dettaglio sono riusati cambiando la sorgente dati via DI.** `OrderOverviewComponent`, `OrderDetailItemsComponent` ecc. leggono da `OrderDetailsService`; la pagina di conferma ordine e quella di dettaglio replenishment sostituiscono quel servizio nei `providers` del mapping CMS con `OrderFacade` o `ReplenishmentOrderDetailsService` (`feature-libs/order/components/order-confirmation/order-confirmation.module.ts:L96-L129`, `feature-libs/order/components/replenishment-order-details/replenishment-order-details.module.ts:L51-L87`).
3. **Le rotte sono semantiche e senza path.** `OrderRootModule` registra 11 rotte con `path: null` e un `data.cxRoute`; i path reali vengono dalla routing config di default (`feature-libs/order/root/order-root.module.ts:L82-L172`, `feature-libs/order/root/config/default-order-routing-config.ts:L9-L54`), secondo il meccanismo descritto nel capitolo 14.

feature-libs/order/styles/components/order-details/_index.scss	Importa gli stili del dettaglio e definisce $order-details-allowlist (include anche i selettori del document flow).
feature-libs/order/styles/components/order-details/_attachments-dialog.scss	Placeholder %cx-order-attachments-dialog.
feature-libs/order/styles/components/order-details/_my-account-v2-order-details.scss	Placeholder v2: %cx-my-account-v2-order-details-actions, %cx-my-account-v2-consignment-tracking, %cx-my-account-v2-download-invoices.
feature-libs/order/styles/components/order-details/_order-attachments.scss	Placeholder %cx-order-attachments.
feature-libs/order/styles/components/order-details/_order-detail-billing.scss	Placeholder %cx-order-detail-billing.
feature-libs/order/styles/components/order-details/_order-details-actions.scss	Placeholder %cx-order-details-actions.
feature-libs/order/styles/components/order-details/_order-details-items.scss	Placeholder %cx-order-details-items.
feature-libs/order/styles/components/order-details/_order-details-reorder.scss	Placeholder %cx-order-details-reorder.
feature-libs/order/styles/components/order-details/_order-details-shipping.scss	Definisce di nuovo %cx-order-overview (stesso placeholder di _order-overview.scss, vedi 3.10).
feature-libs/order/styles/components/order-details/_reorder-dialog.scss	Selettore diretto cx-reorder-dialog (non placeholder, fuori allowlist).
feature-libs/order/styles/components/order-history/_index.scss	Importa cart-item-list da cart base + gli stili storico/amend/resi/tracking; $order-history-allowlist.

PATH	RUOLO
feature-libs/order/styles/components/order-history/_amend-order-actions.scss	Placeholder %cx-amend-order-actions.
feature-libs/order/styles/components/order-history/_amend-order-items.scss	Placeholder %cx-amend-order-items.
feature-libs/order/styles/components/order-history/_cancel-order.scss	Placeholder %cx-cancel-order.
feature-libs/order/styles/components/order-history/_consignment-tracking.scss	Placeholder %cx-consignment-tracking e %cx-tracking-events.
feature-libs/order/styles/components/order-history/_my-account-v2-order-history.scss	Mixin draw-line + placeholder %cx-my-account-v2-order-history.
feature-libs/order/styles/components/order-history/_order-history.scss	Placeholder %cx-order-history.
feature-libs/order/styles/components/order-history/_order-return-request-list.scss	Placeholder %cx-order-return-request-list.
feature-libs/order/styles/components/order-history/_replenishment-order-history.scss	Placeholder %cx-replenishment-order-history.
feature-libs/order/styles/components/order-history/_return-request-items.scss	Placeholder %cx-return-request-items.
feature-libs/order/styles/components/order-history/_return-request-overview.scss	Placeholder %cx-return-request-overview.
feature-libs/order/styles/components/order-history/_return-request-totals.scss	Placeholder %cx-return-request-totals.
feature-libs/order/styles/components/order-overview/_index.scss	Allowlist $order-overview-allowlist (cx-order-overview).
feature-libs/order/styles/components/order-overview/_order-overview.scss	Placeholder %cx-order-overview.
feature-libs/order/styles/components/replenishment-order/_index.scss	Allowlist $replenishment-order-allowlist (cancellation + dialog).
feature-libs/order/styles/components/replenishment-order/_replenishment-order-cancellation.scss	Placeholder %cx-replenishment-order-cancellation e %cx-replenishment-order-cancellation-dialog.
feature-libs/pdf-invoices/_index.scss	Entry SCSS di @spartacus/pdf-invoices: importa @spartacus/styles/scss/core e styles/index.
feature-libs/pdf-invoices/styles/_index.scss	Importa _pdf-invoices.scss.
feature-libs/pdf-invoices/styles/_pdf-invoices.scss	Stili di cx-invoices-list con selettore diretto (nessuna allowlist).
feature-libs/pdf-invoices/assets/public_api.ts	Entry @spartacus/pdf-invoices/assets: riesporta translations/translations.
feature-libs/pdf-invoices/pdf-invoices.module.ts	PDFInvoicesModule = components + core + occ (:L12-L19).
feature-libs/pdf-invoices/public_api.ts	Entry @spartacus/pdf-invoices: riesporta solo il modulo (:L10-L10).
feature-libs/pdf-invoices/schematics/add-pdf-invoices/index.ts	addPDFInvoicesFeature(): factory degli schematics di pdf-invoices (vedi 3.10).

PATH	RUOLO
feature-libs/pdf-invoices/schematics/add-pdf-invoices/index_spec.ts	Test dello schematic pdf-invoices (lazy, scss, angular.json, eager).
feature-libs/pdf-invoices/vitest.config.ts	Config Vitest della libreria: jsdom, pool forks, coverage v8 con soglie 85/65, report junit.

3. Come funziona passo per passo

3.1 Registrazione eager e caricamento lazy

1. **Root eager.** `OrderRootModule` fornisce tre default config: componenti (factory), routing e `defaultOrderConfig` (feature-libs/order/root/order-root.module.ts:L174-L178). La factory dichiara la feature `order` con i 36 tipi CMS di `ORDER_CMS_COMPONENTS` e la dipendenza da `CART_BASE_FEATURE`, e mappa `orderCore` come **alias stringa** di `order` (feature-libs/order/root/order-root.module.ts:L67-L80).
2. **Il `module` lo mette l'app.** Una feature è "configurata" solo se ha la proprietà `module` (core-libs/core/src/lazy-loading/feature-modules.service.ts:L33-L35); il root module non la fornisce. Nell'app demo `OrderFeatureModule` aggiunge `module: () => import('./order-wrapper.module')` (projects/storefrontapp/src/app/spartacus/features/order/order-feature.module.ts:L26-L33), e `OrderWrapperModule` importa `OrderModule` più estensioni condizionali (S/4 service, OMF, OPF) (projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L14-L27).
3. **Facade proxy.** Ogni facade è una classe astratta `providedIn: 'root'` con `useFactory → facadeFactory({ feature: ORDER_CORE_FEATURE, methods: [...] })` (feature-libs/order/root/facade/order.facade.ts:L14-L30). Il proxy è un'istanza di una sottoclasse anonima a cui vengono aggiunti **solo** i metodi elencati (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L117-L127).
4. **Prima chiamata.** `resolveFeature('orderCore')` risolve l'alias con un ciclo `while` (core-libs/core/src/lazy-loading/feature-modules.service.ts:L95-L100), risolve le dipendenze (`cartBase`) e importa il modulo (core-libs/core/src/lazy-loading/feature-modules.service.ts:L42-L73). Il proxy prende poi la facade dall'injector del modulo lazy (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L49-L52), dove `facadeProviders` la lega al servizio concreto con `useExisting` (feature-libs/order/core/facade/facade-providers.ts:L26-L63).
5. **`async: true`.** `OrderHistoryFacade`, `OrderReturnRequestFacade` e `ReplenishmentOrderHistoryFacade` usano `async: true` (feature-libs/order/root/facade/order-history.facade.ts:L41-L41, feature-libs/order/root/facade/order-return-request.facade.ts:L37-L37, feature-libs/order/root/facade/replenishment-order-history.facade.ts:L39-L39), che aggiunge `delay(0)` alla risoluzione (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L53-L56).
6. **Metodi `void` via proxy.** `call()` collega subito un `connectable` con `ReplaySubject`: il metodo reale viene eseguito appena il modulo è risolto anche se il chiamante non si sottoscrive (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L70-L92). Per questo `loadOrderDetails(code)` chiamato sul proxy produce davvero il dispatch.
7. **Core.** `OrderCoreModule` importa `OrderStoreModule` e fornisce i `facadeProviders` più 6 connector (feature-libs/order/core/order-core.module.ts:L17-L29). Lo store è registrato con `StoreModule.forFeature(ORDER_FEATURE, reducerToken)` e `EffectsModule.forFeature(effects)` (feature-libs/order/core/store/order-store.module.ts:L14-L21).
8. **OCC.** `OrderOccModule` fornisce `defaultOccOrderConfig`, lega 6 adapter astratti alle implementazioni `Occ*` e registra 5 converter multi (feature-libs/order/occ/order-occ.module.ts:L38-L90).

3.2 Rotte e contesto

- Rotte di default: `orders` → `my-account/orders`, `orderDetails` → `my-account/order/:orderCode`, `orderGuest` → `guest/order/:orderCode`, cancel/return e relative conferme sotto `my-account/order/...`, `returnRequestDetails` → `my-account/return-request/:returnCode`, replenishment sotto `my-account/my-replenishment(s)`, `replenishmentConfirmation` → `replenishment/confirmation` (nessuna rotta `path: null` in `OrderRootModule`, feature-libs/order/root/order-root.module.ts:L82-L172), `orderConfirmation` → `order-confirmation` (feature-libs/order/root/config/default-order-routing-config.ts:L9-L54).
- `paramsMapping` collega i parametri URL alle proprietà del modello: `orderCode` → `code`, `returnCode` → `rma`, `replenishmentOrderCode` → `replenishmentOrderCode` (feature-libs/order/root/config/default-order-routing-config.ts:L17-L17, :L41-L41, :L48-L48). Per questo `OrderHistoryComponent.goToOrderDetail` può passare l'intero ordine come `params` (feature-libs/order/components/order-history/order-history.component.ts:L119-L129).
- Le rotte `orderGuest`, `orderDetails`, `orders`, `replenishment*`, `returnRequestDetails` hanno `[AuthGuard, CmsPageGuard]`; cancel, return, le loro conferme e `orderConfirmation` hanno solo `CmsPageGuard` (feature-libs/order/root/order-root.module.ts:L104-L131, :L160-L171). Per cancel/return l'`AuthGuard` è nel mapping CMS (feature-libs/order/components/amend-order/cancellations/cancel-order/cancel-order.module.ts:L40-L42).
- `orderDetails` e `orderConfirmation` impostano `cxContext[ORDER_ENTRIES_CONTEXT]` sui token `OrderDetailsOrderEntriesContextToken` / `OrderConfirmationOrderEntriesContextToken` (feature-libs/order/root/order-root.module.ts:L97-L102, :L165-L170). I token sono legati ai contesti concreti rispettivamente in `OrderComponentsModule` e `OrderConfirmationModule` (feature-libs/order/components/order-components.module.ts:L23-L43, feature-libs/order/components/order-confirmation/order-confirmation.module.ts:L132-L135); il primo legge le entry da `OrderHistoryFacade`, il secondo da `OrderFacade` (feature-libs/order/components/page-context/order-details-order-entries.context.ts:L20-L29, feature-libs/order/components/page-context/order-confirmation-order-entries.context.ts:L20-L31).

3.3 Place order e pagina di conferma

1. Il checkout chiama `orderFacade.placeOrder(this.checkoutSubmitForm.valid)` e su `next` naviga a `cxRoute: 'orderConfirmation'` (feature-libs/checkout/base/components/checkout-place-order/checkout-place-order.component.ts:L149-L170).
2. `OrderService.placeOrder` esegue `placeOrderCommand`, creato con `CommandStrategy.CancelPrevious` (feature-libs/order/core/facade/order.service.ts:L26-L54, :L119-L121).
3. `checkoutPreconditions()` prende con `take(1)` userId, id del carrello attivo e flag guest, e lancia `Error('Checkout conditions not met')` se manca uno dei due id o se l'utente è anonimo con carrello non guest (feature-libs/order/core/facade/order.service.ts:L99-L117).
4. `OccOrderAdapter.placeOrder` fa POST con body vuoto, `cartId`/`termsChecked` in query string, `Content-Type: application/x-www-form-urlencoded`, header `USE_CLIENT_TOKEN` per l'utente anonimo (guest) e `backOff({ shouldRetry: isJaloError })`; la risposta passa per `ORDER_NORMALIZER` (feature-libs/order/occ/adapters/occ-order.adapter.ts:L38-L66, :L106-L115).
5. `OccOrderNormalizer` converte entries, entry delle consignment e unconsigned entries con `PRODUCT_NORMALIZER` e `ORDER_ENTRY_PROMOTIONS_NORMALIZER`, aggiungendo `orderCode` (feature-libs/order/occ/adapters/converters/occ-order-normalizer.ts:L25-L81).
6. Al successo: `placedOrder$.next(order)` e dispatch di `OrderPlacedEvent` con `cartCode: cartId` (feature-libs/order/core/facade/order.service.ts:L32-L46). Il JSDoc dell'evento spiega che `cartId` è `code` per utenti loggati e `guid` per anonimi (feature-libs/order/root/events/order.events.ts:L16-L29).

7. `CheckoutPlaceOrderEventListener` reagisce all'evento dispatchando `RemoveCartEvent` e `CheckoutQueryResetEvent` (feature-libs/checkout/base/root/events/checkout-place-order-event.listener.ts:L24-L40).
8. Sulla pagina `/order-confirmation` ogni componente CMS di conferma è protetto da `OrderConfirmationGuard`, che lascia passare solo se `orderFacade.getOrderDetails()` emette un oggetto non vuoto, altrimenti reindirizza a `orders` (feature-libs/order/components/guards/order-confirmation.guard.ts:L24-L36).
9. Overview e Billing della conferma riusano `OrderOverviewComponent` / `OrderDetailBillingComponent` con `OrderDetailsService` sostituito da `OrderFacade` (feature-libs/order/components/order-confirmation/order-confirmation.module.ts:L96-L129). Poiché `OrderFacade` non ha `isOrderDetailsLoading`, i componenti verificano `typeof ... === 'function'` e altrimenti usano `of(false)` (feature-libs/order/components/order-details/order-overview/order-overview.component.ts:L66-L70, feature-libs/order/components/order-details/order-detail-items/order-detail-items.component.ts:L78-L81).
10. `OrderConfirmationModule` aggiunge `OrderConfirmationShippingComponent` all'outlet `CONSIGNMENT_DELIVERY_INFO` (feature-libs/order/components/order-confirmation/order-confirmation.module.ts:L136-L139).
11. Il thank-you message aggiunge un global message `MSG_TYPE_ASSISTIVE` con il codice ordine (o `replenishmentOrderCode`) per gli screen reader (feature-libs/order/components/order-confirmation/order-confirmation-thank-you-message/order-confirmation-thank-you-message.component.ts:L65-L93).
12. In `ngOnDestroy` thank-you message, items e totals chiamano `orderFacade.clearPlacedOrder()` (feature-libs/order/components/order-confirmation/order-confirmation-thank-you-message/order-confirmation-thank-you-message.component.ts:L69-L71, feature-libs/order/components/order-confirmation/order-confirmation-items/order-confirmation-items.component.ts:L41-L43, feature-libs/order/components/order-confirmation/order-confirmation-totals/order-confirmation-totals.component.ts:L26-L28).

Varianti:

- `placePaymentAuthorizedOrder(termsChecked, cartId?)`: con `cartId` esplicito salta il command e le precondizioni sul carrello attivo, controlla solo lo userId e chiama direttamente il connector (feature-libs/order/core/facade/order.service.ts:L123-L156). L'adapter aggiunge un secondo `backOff` su `isServerError` con `maxTries: DEFAULT_SERVER_ERROR_RETRIES_COUNT` (feature-libs/order/occ/adapters/occ-order.adapter.ts:L91-L103).
- **Guest:** `OrderGuestRegisterFormComponent` (host `ngSkipHydration`) registra l'ospite con `userRegisterFacade.registerGuest(guid, password)` (feature-libs/order/components/order-confirmation/order-guest-register-form/order-guest-register-form.component.ts:L30-L91).

3.4 Dettaglio ordine (My Account)

1. Rotta `my-account/order/:orderCode` con `[AuthGuard, CmsPageGuard]` (feature-libs/order/root/order-root.module.ts:L92-L103).
2. I componenti CMS di dettaglio (8 tipi, tutti con `guards: [AuthGuard]`) leggono da `OrderDetailsService` (feature-libs/order/components/order-details/order-details.module.ts:L128-L172).
3. `OrderDetailsService` (`providedIn: 'root'`) deriva `orderCode$` dal param del router con `distinctUntilChanged`; `orderLoad$` chiama `loadOrderDetails(orderCode)` o `clearOrderDetails()` ed è `shareReplay({ bufferSize: 1, refCount: true })` (feature-libs/order/components/order-details/order-details.service.ts:L30-L44).
4. `getOrderDetails()` fa `switchMap` da `orderLoad$` a `orderHistoryFacade.getOrderDetails()`: il caricamento parte solo quando qualcuno si sottoscrive (feature-libs/order/components/order-details/order-

details.service.ts:L51-L55).

5. `OrderHistoryService.loadOrderDetails` prende lo userId e dispatcha `LoadOrderDetails({ userId, orderCode })` (feature-libs/order/core/facade/order-history.service.ts:L50-L59).
6. `OrderDetailsEffect.loadOrderDetails$` chiama `OrderHistoryConnector.get` e mappa in `LoadOrderDetailsSuccess/Fail` con `tryNormalizeHttpError` (feature-libs/order/core/store/effects/order-details.effect.ts:L35-L57).
7. `OccOrderHistoryAdapter.load` fa GET su `orderDetail` (`?fields=FULL`), con `USE_CLIENT_TOKEN` se l'utente è anonimo, e normalizza con `ORDER_NORMALIZER` (feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L57-L68). Con `showOrderQuoteLink` attivo l'URL è la fusione degli scope `orderDetail` e `quoteCode` tramite `OccFieldsService.getOptimalUrlGroups` (feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L212-L231).
8. Il success finisce nella slice `orderDetail` (`loaderReducer(ORDER_DETAILS, ...)`) (feature-libs/order/core/store/reducers/index.ts:L45-L48) e il selettore `getOrderDetails` lo restituisce (feature-libs/order/core/store/selectors/order-details.selectors.ts:L18-L21).
9. Al cambio di lingua o valuta `resetOrderDetails$` ricarica l'ordine corrente (codice letto dallo store con `withLatestFrom`), altrimenti `EMPTY` (feature-libs/order/core/store/effects/order-details.effect.ts:L87-L120).

Sopra questo flusso:

- **Azioni.** Il template mostra i link `orderCancel` se `order.cancellable` e `orderReturn` se `order.returnable` (feature-libs/order/components/order-details/order-detail-actions/order-detail-actions.component.html:L13-L39).
- **Consegne.** `OrderDetailItemsComponent` raggruppa consegne in pickup/delivery tramite `MyAccountV2OrderConsignmentsService` (feature-libs/order/components/order-details/order-detail-items/order-detail-items.component.ts:L61-L72), che ordina per stato: in lavorazione, completate (`DELIVERY_COMPLETED`, `PICKUP_COMPLETE`), cancellate (feature-libs/order/components/order-details/my-account-v2-order-consignments.service.ts:L50-L81, feature-libs/order/components/order-details/order-detail-items/order-consigned-entries/order-consigned-entries.model.ts:L7-L8).
- **Tracking.** `ConsignmentTrackingComponent.openTrackingDialog` chiama `loadConsignmentTracking(orderCode, consignment.code)` e apre il dialog `CONSIGNMENT_TRACKING` con `tracking$` e `shipDate` (feature-libs/order/components/order-details/order-detail-items/consignment-tracking/consignment-tracking.component.ts:L61-L87); il pulsante esiste per gli stati SHIPPED, IN_TRANSIT, DELIVERY_COMPLETED, DELIVERY_REJECTED, DELIVERING (feature-libs/order/components/order-details/order-detail-items/consignment-tracking/consignment-tracking.component.ts:L35-L41). Il template mostra il tracking dietro `*cxFeature="'consignmentTracking'"` (feature-libs/order/components/order-details/order-detail-items/order-consigned-entries/order-consigned-entries.component.html:L19-L19), con feature level `'1.2'` impostato dallo stesso modulo (feature-libs/order/components/order-details/order-details.module.ts:L173-L175).
- **Link al preventivo.** `OrderOverviewComponent` mostra il link a `quoteDetails` solo se `orderConfig.showOrderQuoteLink && quoteCode` (feature-libs/order/components/order-details/order-overview/order-overview.component.html:L178-L195).

3.5 Lista ordini

1. `OrderHistoryComponent.orders$ = getOrderHistoryList(5)` (feature-libs/order/components/order-history/order-history.component.ts:L61-L71).
2. `getOrderHistoryList` implementa "load on subscribe": se lo stato loader non è né loading né success né error chiama `loadOrderList(pageSize)`, poi mappa `value` (feature-libs/order/core/facade/order-

history.service.ts:L71-L87).

3. `loadOrderList` richiede utente loggato (`takeUserId(true)`), legge in modo sincrono `replenishmentOrderCode` dai params del router e dispatcha `LoadUserOrders`; l'errore è inghiottito con un TODO (feature-libs/order/core/facade/order-history.service.ts:L102-L130). `takeUserId(true)` lancia per l'utente anonimo (core-libs/core/src/auth/user-auth/facade/user-id.service.ts:L57-L69).
4. `OrdersEffect.loadUserOrders$` sceglie la sorgente: con `replenishmentOrderCode` usa `loadReplenishmentDetailsHistory`, altrimenti `getHistory` (feature-libs/order/core/store/effects/orders.effect.ts:L33-L68).
5. `OccOrderHistoryAdapter.loadHistory` aggiunge `pageSize`, `currentPage`, `sort` in query solo se truthy (feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L70-L95).
6. Cambio sort/pagina → `loadOrderList(PAGE_SIZE, currentPage, sortCode)`; `ngOnDestroy` → `clearOrderList()` (feature-libs/order/components/order-history/order-history.component.ts:L98-L155).
7. `resetUserOrders$` svuota la lista al cambio lingua (feature-libs/order/core/store/effects/orders.effect.ts:L70-L78).

3.6 Cancellazione e reso (amend order)

1. `OrderAmendService` è astratto: `getEntries()` e `save()` sono astratti; il form viene costruito per ordine e ricostruito se cambia `orderCode` (feature-libs/order/components/amend-order/amend-order.service.ts:L34-L84).
2. Il form ha un controllo per entry (chiave `entryNumber`) con `Validators.min(0)` e `max(getMaxAmendQuantity(entry))`; il gruppo `entries` ha il validatore `ValidateQuantityToCancel` (somma > 0, errore `cxNoSelectedItemToCancel`) (feature-libs/order/components/amend-order/amend-order.service.ts:L23-L32, :L86-L108). Il massimo è `cancellableQuantity` o `returnableQuantity` con fallback su `quantity` (feature-libs/order/components/amend-order/amend-order.service.ts:L140-L148).
3. Il servizio concreto entra tramite i `providers` del mapping CMS: `{ provide: OrderAmendService, useExisting: OrderCancellationService }` (feature-libs/order/components/amend-order/cancellations/cancel-order/cancel-order.module.ts:L38-L51).
4. `AmendOrderActionsComponent.continue` naviga a `forwardRoute` con `params: { code: orderCode }` se il form è valido, altrimenti `markAllAsTouched` (feature-libs/order/components/amend-order/amend-order-actions/amend-order-actions.component.ts:L35-L45).
5. Le pagine di conferma hanno guard `[AuthGuard, OrderCancellationGuard]` (o `OrderReturnGuard`); la guard reindirizza a `orders` se il form non è valido (feature-libs/order/components/amend-order/cancellations/cancel-order-confirmation/cancel-order-confirmation.module.ts:L29-L31, feature-libs/order/components/amend-order/cancellations/order-cancellation.guard.ts:L24-L38).
6. **Cancel.** `OrderCancellationService.getEntries` esclude `entryNumber === -1` e le entry senza `cancellableQuantity > 0` (feature-libs/order/components/amend-order/cancellations/order-cancellation.service.ts:L41-L54). `save()` costruisce gli input, resetta il form, chiama `cancelOrder`, attende `getCancelOrderSuccess()` con `first(Boolean)`, poi resetta il process state, mostra `cancelSuccess` e naviga a `orders` (feature-libs/order/components/amend-order/cancellations/order-cancellation.service.ts:L56-L93).
7. Il flag di successo viene dal process store: `ProcessSelectors.getProcessSuccessFactory(CANCEL_ORDER_PROCESS_ID)` (feature-libs/order/core/facade/order-history.service.ts:L191-L204); l'azione `CancelOrder` estende `EntityLoadAction` su `PROCESS_FEATURE` (feature-libs/order/core/store/actions/order-details.action.ts:L60-L95).
8. `cancelOrder$` chiama il connector (POST JSON su `cancelOrder`) e in errore aggiunge un global message per ciascun `error.error.errors[].message` (feature-libs/order/core/store/effects/order-details.

effect.ts:L59-L85, feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L110-L127).

9. **Reso.** `ReturnOrderComponent` tiene solo le entry con una consignment entry dello stesso codice prodotto e usa `shippedQuantity` come nuovo `returnableQuantity` solo nelle entry passate alla UI (feature-libs/order/components/amend-order/returns/return-order/return-order.component.ts:L42-L73); il `Validators.max` del form resta sul valore originale (feature-libs/order/components/amend-order/amend-order.service.ts:L96-L106). `OrderReturnService.save` chiama `createOrderReturnRequest`, attende `getReturnRequestSuccess()`, legge il `ReturnRequest` creato e naviga a `returnRequestDetails` con `params: { rma }` (feature-libs/order/components/amend-order/returns/order-return.service.ts:L54-L99).
10. `createReturnRequest` serializza con `ORDER_RETURN_REQUEST_INPUT_SERIALIZER` e normalizza con `ORDER_RETURN_REQUEST_NORMALIZER` (feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L129-L151). Create e load del reso condividono l'entity type `RETURN_REQUEST_DETAILS`, quindi scrivono nella stessa slice `orderReturn` (feature-libs/order/core/store/actions/order-return-request.action.ts:L55-L117).
11. **Dettaglio reso.** `ReturnRequestService.getReturnRequest` legge `returnCode` dal router e carica il dettaglio se assente o con `rma` diverso e non in loading (feature-libs/order/components/return-request-detail/return-request.service.ts:L35-L59). La cancellazione invia `{ status: 'CANCELLING' }` (PATCH su `cancelReturn`) (feature-libs/order/components/return-request-detail/return-request.service.ts:L65-L69, feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L193-L210); `backToList()` torna a `orders` con `state: { activeTab: 1 }` (feature-libs/order/components/return-request-detail/return-request.service.ts:L85-L94).

3.7 Reorder

1. `OrderDetailReorderComponent` disabilita il pulsante se nessuna entry ha un prodotto ancora in catalogo e apre il dialog `REORDER` con `{ orderCode }` (feature-libs/order/components/order-details/order-detail-reorder/order-detail-reorder.component.ts:L46-L74).
2. `ReorderDialogComponent.createCartFromOrder` chiama `reorderOrderFacade.reorder`, poi `multiCartFacade.reloadCart(OCC_CART_ID_CURRENT, { active: true })` e mostra le `cartModifications`; in errore aggiunge `reorder.dialog.error` e chiude (feature-libs/order/components/order-details/order-detail-reorder/reorder-dialog/reorder-dialog.component.ts:L77-L96).
3. `ReorderOrderService` usa un command `CancelPrevious`: prima `reorderPreconditions()`, poi `ReorderOrderConnector.reorder(orderId, userId)` (feature-libs/order/core/facade/reorder-order.service.ts:L26-L37).
4. Le precondizioni falliscono con `'Must be logged in to reorder'` se manca lo userId; se esiste un carrello attivo lo cancellano e attendono che l'entità non sia in loading e sia assente o in errore (feature-libs/order/core/facade/reorder-order.service.ts:L56-L92).
5. `OccReorderOrderAdapter` fa POST JSON con body vuoto su `reorder` con `orderCode` in query (feature-libs/order/occ/adapters/occ-reorder-order.adapter.ts:L31-L51). L'endpoint non ha default nella libreria order: esiste in `defaultB2bOccConfig` (feature-libs/order/occ/model/occ-order-endpoints.model.ts:L86-L93, core-libs/setup/recipes/b2b/config/default-b2b-occ-config.ts:L31-L36).

3.8 Replenishment

1. **Schedulazione** (dal checkout scheduled replenishment): `ScheduledReplenishmentOrderService` usa un command `CancelPrevious`, chiama il connector con `(cartId, form, termsChecked, userId)` e al successo fa `orderFacade.setPlacedOrder(replenishmentOrder)` e dispatcha `ReplenishmentOrderScheduledEvent` (feature-libs/order/core/facade/scheduled-replenishment-order.service.ts:L32-L68). Le precondizioni sono quelle del place order con messaggio `'Order conditions not met'` (feature-libs/order/core/facade/scheduled-replenishment-order.service.ts:L79-L97).

2. L'adapter serializza il form con `REPLENISHMENT_ORDER_FORM_SERIALIZER` (`feature-libs/order/occ/adapters/occ-scheduled-replenishment-order.adapter.ts:L39-L82`); il serializer trasforma `replenishmentStartDate` `YYYY-mm-dd` aggiungendo ora locale, `:00` e offset del fuso (`feature-libs/order/occ/adapters/converters/occ-scheduled-replenishment-order-form-serializer.ts:L34-L46`).
3. **Storico e dettaglio** passano per NgRx: `ReplenishmentOrderHistoryService` usa `takeUserId(true)` per caricare dettagli, lista e cancellare (`feature-libs/order/core/facade/replenishment-order-history.service.ts:L43-L57`). `ReplenishmentOrderDetailsService` replica il pattern di `OrderDetailsService` sul param `replenishmentOrderCode` (`feature-libs/order/components/replenishment-order-details/replenishment-order-details.service.ts:L25-L55`).
4. **Ordini generati.** Nella pagina di dettaglio replenishment, `ReplenishmentDetailOrderHistoryComponent` è mappato su `OrderHistoryComponent` (`feature-libs/order/components/replenishment-order-details/replenishment-order-details.module.ts:L51-L87`); `loadOrderList` trova `replenishmentOrderCode` nei params e `OrdersEffect` usa l'endpoint `replenishmentOrderDetailsHistory` (`feature-libs/order/core/facade/order-history.service.ts:L107-L123`, `feature-libs/order/core/store/effects/orders.effect.ts:L39-L47`).
5. **Cancellazione.** `ReplenishmentOrderHistoryComponent.openDialog` apre `REPLENISHMENT_ORDER` (`feature-libs/order/components/replenishment-order-history/replenishment-order-history.component.ts:L132-L144`); l'adapter fa PATCH con body `{}` (`feature-libs/order/occ/adapters/occ-replenishment-order-history.adapter.ts:L43-L87`); `CANCEL_REPLENISHMENT_ORDER_SUCCESS` aggiorna sia la lista (sostituendo l'elemento) sia il dettaglio (`feature-libs/order/core/store/reducers/replenishment-orders.reducer.ts:L30-L49`, `feature-libs/order/core/store/reducers/replenishment-order-details.reducer.ts:L16-L20`).

3.9 Allegati, My Account v2, document flow, PDF invoices

- **Allegati.** `OrderAttachmentsService` chiama il connector dopo `takeUserId().pipe(take(1))`, senza store (`feature-libs/order/core/facade/order-attachments.service.ts:L16-L45`). Il dialog carica `sapAttachments` (fallback `[]`) (`feature-libs/order/components/order-details/order-attachments/attachments-dialog/order-attachments-dialog.component.ts:L72-L90`); al click scarica il blob (`responseType: 'blob' as 'json'`, `feature-libs/order/occ/adapters/occ-order-attachments.adapter.ts:L31-L65`) e, se il MIME è in `previewMimeTypes`, lo apre in una nuova scheda, altrimenti forza il download (`feature-libs/order/components/order-details/order-attachments/attachments-dialog/order-attachments-dialog.component.ts:L95-L145`).
- **My Account v2.** Il token `USE_MY_ACCOUNT_V2_ORDER` (default `false`, `feature-libs/order/root/tokens/context.ts:L17-L20`) attiva tre cambiamenti: mapping di `AccountOrderDetailsActionsComponent` → `MyAccountV2OrderDetailsActionsComponent` (`feature-libs/order/components/order-details/order-details.module.ts:L80-L87`, `:L180-L182`), un `MODULE_INITIALIZER` che mette `MyAccountV2ConsignmentTrackingComponent` in `OrderOutlets.ORDER_CONSIGNMENT` con `OutletPosition.REPLACE` (`feature-libs/order/components/order-details/order-details.module.ts:L61-L78`, `:L183-L187`), e `AccountOrderHistoryComponent` → `MyAccountV2OrderHistoryComponent` (`feature-libs/order/components/order-history/order-history.module.ts:L34-L41`, `:L65-L77`). `MyAccountV2OrderHistoryService` arricchisce ogni ordine della lista con dettaglio completo (`LoadOrderById`, slice entity `orderById`), tracking delle consegne con `trackingID` e resi associati (`feature-libs/order/core/facade/my-account-v2-order-history.service.ts:L46-L174`, `:L198-L213`).
- **Download fatture v2.** È event-driven: `MyAccountV2OrderDetailsActionsComponent.showDialog` dispatcha `DownloadOrderInvoicesEvent`; `MyAccountV2DownloadInvoicesEventListener` apre il dialog `DOWNLOAD_ORDER_INVOICES` (`feature-libs/order/components/order-details/my-account-v2/order-details-actions/my-account-v2-order-details-actions.component.ts:L31-L35`, `feature-libs/order/components/order-details/my-account-v2/download-invoices/my-account-v2-download-invoices-event.listener.`

ts:L24-L41), che incorpora `InvoicesListComponent` di `@spartacus/pdf-invoices` (feature-libs/order/components/order-details/my-account-v2/download-invoices/my-account-v2-download-invoices.component.ts:L41-L65).

- **Document flow.** Feature separata `orderDocumentFlow` con un solo tipo CMS, `AccountOrderDocumentFlowComponent`, senza `dependencies` (feature-libs/order/document-flow/root/order-document-flow-root.module.ts:L11-L22). `OrderDocumentFlowFacade` espone `getOrderSubsequentDocuments` e `getOrderSubsequentDocumentEntries` (feature-libs/order/document-flow/root/facade/order-document-flow.facade.ts:L17-L45); il componente riusa `OrderDetailsService` e apre il dialog `ORDER_DOCUMENT_FLOW` (feature-libs/order/document-flow/components/order-document-flow/order-document-flow.component.ts:L29-L46), che mette in cache le entry per documento (feature-libs/order/document-flow/components/order-document-flow-dialog/order-document-flow-dialog.component.ts:L111-L177). Gli endpoint sono `subsequentDocuments` e `subsequentDocumentsEntries` (feature-libs/order/document-flow/occ/config/default-occ-document-flow-config-factory.ts:L10-L24).
- **PDF invoices.** Feature `pdfInvoices` con alias `pdfInvoicesCore` e CMS `AccountOrderDetailsPDFInvoicesComponent` (feature-libs/pdf-invoices/root/pdf-invoices-root.module.ts:L14-L33). `PDFInvoicesFacade` è lazy sulla feature `pdfInvoices` (feature-libs/pdf-invoices/root/facade/pdf-invoices.facade.ts:L16-L22). `PDFInvoicesService` memorizza `userId` e `orderId` (dal param `orderCode`) nel costruttore e li usa come fallback (feature-libs/pdf-invoices/core/services/pdf-invoices.service.ts:L25-L76). `PDFInvoicesBadRequestHandler` (400) traduce gli `UnknownIdentifierError` su `Order`/`Invoice` in messaggi dedicati (feature-libs/pdf-invoices/core/http-interceptors/bad-request/pdf-invoices-badrequest.handler.ts:L20-L90). `InvoicesListComponent` usa page size 5 e forza `fields: DEFAULT` sugli aggiornamenti successivi (feature-libs/pdf-invoices/components/invoices-list/invoices-list.component.ts:L67-L155); il download passa per `FileDownloadService.download(url, '<invoiceId>.pdf')` (feature-libs/pdf-invoices/components/invoices-list/invoices-list.component.ts:L171-L182).

3.10 Installazione via schematics e stili

- **Schematics.** `addOrderFeatures()` legge il `package.json` dell'app, valida l'installazione Spartacus, risolve le dipendenze tra feature con `analyzeCrossFeatureDependencies` e concatena `analyzeApplication`, `addFeatures`, `addPackageJsonDependenciesForLibrary(peerDependencies, ...)` e `finalizeInstallation` (feature-libs/order/schematics/add-order/index.ts:L25-L43). La stessa funzione è registrata sia come `ng-add` (privato, nascosto, alias `install`) sia come `add` (feature-libs/order/schematics/collection.json:L4-L16). Il test verifica che i moduli feature di cart base e user **non** vengano generati (feature-libs/order/schematics/add-order/index_spec.ts:L99-L107). `addPDFInvoicesFeature()` ha corpo identico (feature-libs/pdf-invoices/schematics/add-pdf-invoices/index.ts:L25-L45), ma il suo spec non contiene il test "should NOT install the required feature dependencies" (feature-libs/pdf-invoices/schematics/add-pdf-invoices/index_spec.ts:L79-L123).
- **Stili.** Ogni gruppo SCSS segue lo schema allowlist + `@extend %<selettore> !optional`, saltando i selettori presenti in `$skipComponentStyles` (feature-libs/order/styles/components/order-details/_index.scss:L11-L37). L'allowlist del dettaglio elenca anche `cx-order-document-flow` e `cx-order-document-flow-dialog`, i cui placeholder stanno però in feature-libs/order/document-flow/styles/_document-flow.scss:L1-L1. Il placeholder `%cx-order-overview` è definito due volte, in feature-libs/order/styles/components/order-overview/_order-overview.scss:L1-L1 e in feature-libs/order/styles/components/order-details/_order-details-shipping.scss:L1-L1: Sass unisce le regole di entrambi. `cx-reorder-dialog` (feature-libs/order/styles/components/order-details/_reorder-dialog.scss:L1-L1) e `cx-invoices-list` (feature-libs/pdf-invoices/styles/_pdf-invoices.scss:L1-L1) usano invece selettori diretti, quindi `$skipComponentStyles` non li può escludere.

4. Diagrammi

4.1 Struttura a livelli e caricamento lazy

---

5. Estratti di codice reale

5.1 Feature, alias core e dipendenza dal carrello

feature-libs/order/root/order-root.module.ts:L67-L80

```ts
// TODO: Inline this factory when we start releasing Ivy compiled libraries
export function defaultOrderComponentsConfig(): CmsConfig {
  const config: CmsConfig = {
    featureModules: {
      [ORDER_FEATURE]: {
        cmsComponents: ORDER_CMS_COMPONENTS,
        dependencies: [CART_BASE_FEATURE],
      },
      // by default core is bundled together with components
      [ORDER_CORE_FEATURE]: ORDER_FEATURE,
    },
  };
  return config;
}
```

5.2 Rotta senza path con contesto

feature-libs/order/root/order-root.module.ts:L92-L103

```ts
      {
        // @ts-ignore
        path: null,
        canActivate: [AuthGuard, CmsPageGuard],
        component: PageLayoutComponent,
        data: {
          cxRoute: 'orderDetails',
          cxContext: {
            [ORDER_ENTRIES_CONTEXT]: OrderDetailsOrderEntriesContextToken,
          },
        },
      },
```

5.3 La facade lazy dello storico (e il metodo dimenticato)

feature-libs/order/root/facade/order-history.facade.ts:L19-L43

```ts
export function orderHistoryFacadeFactory() {
  return facadeFactory({
    // @ts-ignore: Deprecated methods will be removed with next major release
    facade: OrderHistoryFacade,
    feature: ORDER_CORE_FEATURE,
    methods: [
      'getOrderDetails',
      'loadOrderDetails',
      'clearOrderDetails',
      'getOrderHistoryList',
      // ...
      'getOrderDetailsLoading',
    ],
    async: true,
  });
}
```

`getQueryParams` è dichiarato `abstract` e `@deprecated` più in basso nella stessa classe ma non compare nei `methods` (feature-libs/order/root/facade/order-history.facade.ts:L144-L148).

5.4 Place order: Command e stato in memoria

feature-libs/order/core/facade/order.service.ts:L22-L54

```ts
@Injectable()
export class OrderService implements OrderFacade {
  protected placedOrder$ = new BehaviorSubject<Order | undefined>(undefined);

  protected placeOrderCommand: Command<boolean, Order> =
    this.commandService.create<boolean, Order>(
      (payload) =>
        this.checkoutPreconditions().pipe(
          switchMap(([userId, cartId]) =>
            this.orderConnector.placeOrder(userId, cartId, payload).pipe(
              tap((order) => {
                this.placedOrder$.next(order);
                this.eventService.dispatch(
                  {
                    userId,
                    cartId,
                    /**
                     * As we know the cart is not anonymous (precondition checked),
                     * we can safely use the cartId, which is actually the cart.code.
                     */
                    cartCode: cartId,
                    order,
                  },
                  OrderPlacedEvent
```

```
              );
            })
          )
        )
      ),
    {
      strategy: CommandStrategy.CancelPrevious,
    }
  );
```

5.5 Precondizioni del checkout

feature-libs/order/core/facade/order.service.ts:L99-L117

```ts
protected checkoutPreconditions(): Observable<[string, string]> {
  return combineLatest([
    this.userIdService.takeUserId(),
    this.activeCartFacade.takeActiveCartId(),
    this.activeCartFacade.isGuestCart(),
  ]).pipe(
    take(1),
    map(([userId, cartId, isGuestCart]) => {
      if (
        !userId ||
        !cartId ||
        (userId === OCC_USER_ID_ANONYMOUS && !isGuestCart)
      ) {
        throw new Error('Checkout conditions not met');
      }
      return [userId, cartId];
    })
  );
}
```

5.6 Adapter OCC del place order

feature-libs/order/occ/adapters/occ-order.adapter.ts:L38-L66

```ts
public placeOrder(
  userId: string,
  cartId: string,
  termsChecked: boolean
): Observable<Order> {
  let headers = new HttpHeaders({
    'Content-Type': 'application/x-www-form-urlencoded',
  });
```

```
  if (userId === OCC_USER_ID_ANONYMOUS) {
    headers = InterceptorUtil.createHeader(USE_CLIENT_TOKEN, true, headers);
  }

  return this.http
    .post<Occ.Order>(
      this.getPlaceOrderEndpoint(userId, cartId, termsChecked.toString()),
      {},
      { headers }
    )
    .pipe(
      catchError((error) => {
        throw tryNormalizeHttpError(error, this.logger);
      }),
      backOff({
        shouldRetry: isJaloError,
      }),
      this.converter.pipeable(ORDER_NORMALIZER)
    );
}
```

5.7 La guard della pagina di conferma

feature-libs/order/components/guards/order-confirmation.guard.ts:L24-L36

```ts
canActivate(): Observable<GuardResult> {
  return this.orderFacade.getOrderDetails().pipe(
    map((orderDetails) => {
      if (orderDetails && Object.keys(orderDetails).length !== 0) {
        return true;
      } else {
        return this.router.parseUrl(
          this.semanticPathService.get('orders') ?? ''
        );
      }
    })
  );
}
```

5.8 Riuso dei componenti di dettaglio sostituendo la sorgente dati

feature-libs/order/components/order-confirmation/order-confirmation.module.ts:L96-L105

```ts
      OrderConfirmationOverviewComponent: {
        component: OrderOverviewComponent,
        providers: [
          {
```

```
            provide: OrderDetailsService,
            useExisting: OrderFacade,
          },
        ],
        guards: [OrderConfirmationGuard],
      },
```

5.9 `OrderDetailsService`: il router guida il caricamento

feature-libs/order/components/order-details/order-details.service.ts:L30-L55

```ts
  this.orderCode$ = this.routingService.getRouterState().pipe(
    map((routingData) => routingData.state.params.orderCode),
    distinctUntilChanged()
  );

  this.orderLoad$ = this.orderCode$.pipe(
    tap((orderCode) => {
      if (orderCode) {
        this.orderHistoryFacade.loadOrderDetails(orderCode);
      } else {
        this.orderHistoryFacade.clearOrderDetails();
      }
    }),
    shareReplay({ bufferSize: 1, refCount: true })
  );
}

isOrderDetailsLoading(): Observable<boolean> {
  return this.orderHistoryFacade.getOrderDetailsLoading();
}

getOrderDetails(): Observable<Order> {
  return this.orderLoad$.pipe(
    switchMap(() => this.orderHistoryFacade.getOrderDetails())
  );
}
```

5.10 "Load on subscribe" della lista ordini

feature-libs/order/core/facade/order-history.service.ts:L71-L87

```ts
getOrderHistoryList(
  pageSize: number
): Observable<OrderHistoryList | undefined> {
  return this.store.pipe(
    select(OrderSelectors.getOrdersState),
```

```
    tap((orderListState) => {
      const attemptedLoad =
        orderListState.loading ||
        orderListState.success ||
        orderListState.error;
      if (!attemptedLoad) {
        this.loadOrderList(pageSize);
      }
    }),
    map((orderListState) => orderListState.value)
  );
}
```

5.11 Lista ordini o ordini generati da un replenishment

feature-libs/order/core/store/effects/orders.effect.ts:L33-L53

```ts
loadUserOrders$: Observable<OrderActions.UserOrdersAction> = createEffect(
  () =>
    this.actions$.pipe(
      ofType(OrderActions.LOAD_USER_ORDERS),
      map((action: OrderActions.LoadUserOrders) => action.payload),
      switchMap((payload) => {
        return (
          payload.replenishmentOrderCode
            ? this.replenishmentOrderConnector.loadReplenishmentDetailsHistory(
                payload.userId,
                payload.replenishmentOrderCode ?? '',
                payload.pageSize,
                payload.currentPage,
                payload.sort
              )
            : this.orderConnector.getHistory(
                payload.userId,
                payload.pageSize,
                payload.currentPage,
                payload.sort
              )
```

5.12 Lo stato della feature

feature-libs/order/core/store/order-state.ts:L37-L47

```ts
export interface OrderState {
  orders: StateUtils.LoaderState<OrderHistoryList>;
  orderDetail: StateUtils.LoaderState<Order>;
  replenishmentOrders: StateUtils.LoaderState<ReplenishmentOrderList>;
```

```
  orderReturn: StateUtils.LoaderState<ReturnRequest>;
  orderReturnList: StateUtils.LoaderState<ReturnRequestList>;
  consignmentTracking: ConsignmentTrackingState;
  replenishmentOrder: StateUtils.LoaderState<ReplenishmentOrder>;
  consignmentTrackingById: StateUtils.EntityLoaderState<ConsignmentTracking>;
  orderById: StateUtils.EntityLoaderState<Order>;
}
```

5.13 Form di amend e prezzo calcolato lato client

feature-libs/order/components/amend-order/amend-order.service.ts:L86-L108

```ts
  private buildForm(order: Order): void {
    this.form = new UntypedFormGroup({});
    this.form.addControl('orderCode', new UntypedFormControl(order.code));

    const entryGroup = new UntypedFormGroup(
      {},
      { validators: [ValidateQuantityToCancel] }
    );
    this.form.addControl('entries', entryGroup);

    (order.entries || []).forEach((entry) => {
      const key = entry?.entryNumber?.toString() ?? '';
      entryGroup.addControl(
        key,
        new UntypedFormControl(0, {
          validators: [
            Validators.min(0),
            Validators.max(this.getMaxAmendQuantity(entry)),
          ],
        })
      );
    });
  }
```

feature-libs/order/components/amend-order/amend-order.service.ts:L119-L135

```ts
  /**
   * As discussed, this calculation is moved to SPA side.
   * The calculation and validation should be in backend facade layer.
   */
  getAmendedPrice(entry: OrderEntry): Price {
    const amendedQuantity = this.getFormControl(this.form, entry).value;
    const amendedPrice = Object.assign({}, entry.basePrice);
    amendedPrice.value =
      Math.round((entry.basePrice?.value ?? 0) * amendedQuantity * 100) / 100;
```

```
  amendedPrice.formattedValue = formatCurrency(
    amendedPrice.value,
    // TODO: user current language
    'en',
    getCurrencySymbol(amendedPrice.currencyIso ?? '', 'narrow'),
    amendedPrice.currencyIso
  );
```

5.14 Cancellazione: attesa sul process state

feature-libs/order/components/amend-order/cancellations/order-cancellation.service.ts:L56-L79

```ts
save(): void {
  const orderCode = this.form.value.orderCode;
  const entries = this.form.value.entries;
  const inputs: CancelOrReturnRequestEntryInput[] = Object.keys(entries)
    .filter((entryNumber) => <number>entries[entryNumber] > 0)
    .map(
      (entryNumber) =>
        ({
          orderEntryNumber: Number(entryNumber),
          quantity: <number>entries[entryNumber],
        }) as CancelOrReturnRequestEntryInput
    );

  this.form.reset();

  this.orderHistoryFacade.cancelOrder(orderCode, {
    cancellationRequestEntryInputs: inputs,
  });

  this.orderHistoryFacade
    .getCancelOrderSuccess()
    .pipe(first(Boolean))
    .subscribe(() => this.afterSave(orderCode));
}
```

5.15 Reorder: cancella il carrello e aspetta

feature-libs/order/core/facade/reorder-order.service.ts:L56-L92

```ts
protected reorderPreconditions(): Observable<string> {
  return combineLatest([
    this.userIdService.takeUserId(),
    this.activeCartFacade.getActiveCartId(),
  ]).pipe(
    take(1),
```

```
    switchMap(([userId, cartId]) => {
      if (!userId) {
        return throwError(() => new Error('Must be logged in to reorder'));
      }

      if (cartId) {
        return this.deleteCartAndWait(cartId, userId);
      }

      return of(userId);
    })
  );
}

protected deleteCartAndWait(
  cartId: string,
  userId: string
): Observable<string> {
  this.multiCartFacade.deleteCart(cartId, userId);
  // Wait for the cart entity to be fully removed from the store
  // before proceeding with the reorder.
  return this.multiCartFacade.getCartEntity(cartId).pipe(
    filter((state) => !state.loading && (!state.value || !!state.error)),
    take(1),
    switchMap((state) =>
      state.error
        ? throwError(() => new Error('Failed to delete cart before reorder'))
        : of(userId)
    )
  );
}
```

5.16 Reso: abbinamento entry ↔ consegna per codice prodotto

feature-libs/order/components/amend-order/returns/return-order/return-order.component.ts:L42-L73

TS

```
entries$: Observable<OrderEntry[]> = combineLatest([
  this.orderAmendService.getEntries(),
  this.consignments$,
]).pipe(
  map(([entries, consignments]) => {
    // Flatten all consignment entries
    const consignmentEntries = consignments.flatMap(
      (consignment) => consignment.entries ?? []
    );
    return entries
      .map<OrderEntry | null>((entry) => {
        // Find matching consignment entry by product code
```

```
          const consignmentEntry = consignmentEntries.find(
            (ce) => ce.orderEntry?.product?.code === entry.product?.code
          );
          // If found, update the max quantity with shippedQuantity
          return consignmentEntry
            ? {
                ...entry,
                returnableQuantity:
                  consignmentEntry.shippedQuantity ??
                  entry.returnableQuantity ??
                  0,
              }
            : null;
        })
        .filter(
          (entry): entry is OrderEntry =>
            !!entry && entry.returnableQuantity !== 0
        );
    })
  );
```

5.17 Outlet registrato condizionalmente (My Account v2)

feature-libs/order/components/order-details/order-details.module.ts:L61-L78

```ts
function registerOrderOutletFactory(): () => void {
  const isMyAccountV2 = inject(USE_MY_ACCOUNT_V2_ORDER);
  const outletService = inject(OutletService);
  const componentFactoryResolver = inject(ComponentFactoryResolver);
  return () => {
    const config: ProvideOutletOptions = {
      component: MyAccountV2ConsignmentTrackingComponent,
      id: OrderOutlets.ORDER_CONSIGNMENT,
      position: OutletPosition.REPLACE,
    };
    if (isMyAccountV2) {
      const template = componentFactoryResolver.resolveComponentFactory(
        config.component
      );
      outletService.add(config.id, template, config.position);
    }
  };
}
```

5.18 Endpoint e URL del dettaglio con quote code

feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L212-L231

```ts
protected getOrderDetailUrl(userId: string, orderCode: string): string {
  return this.orderConfig.showOrderQuoteLink
    ? (() => {
        const scopes = ['orderDetail', 'quoteCode'];
        const scopedDataWithUrls: ScopedDataWithUrl[] = scopes.map(
          (scope) => ({
            scopedData: { scope, userId, orderCode },
            url: this.occEndpoints.buildUrl(scope, {
              urlParams: { userId, orderId: orderCode },
            }),
          })
        );
        const mergedUrl =
          this.occFieldsService.getOptimalUrlGroups(scopedDataWithUrls);
        return Object.keys(mergedUrl)[0];
      })()
    : this.occEndpoints.buildUrl('orderDetail', {
        urlParams: { userId, orderId: orderCode },
      });
}
```

Note: OrderConfig è una classe astratta providedIn: 'root' con useExisting: Config che augmenta Config di @spartacus/core (feature-libs/order/root/config/order-config.ts:L10-L23); OrderOccEndpoints augmenta OccEndpoints (feature-libs/order/occ/model/occ-order-endpoints.model.ts:L104-L106). L'app demo B2B applica defaultB2bOccConfig con provideConfig (projects/storefrontapp/src/app/spartacus/spartacus-b2b-configuration.providers.ts:L10-L20).

7. Commenti e note notevoli dal sorgente

- // by default core is bundled together with components — spiega perché orderCore è un alias di order: core e componenti stanno nello stesso chunk (feature-libs/order/root/order-root.module.ts:L75-L75, uguale in feature-libs/pdf-invoices/root/pdf-invoices-root.module.ts:L20-L20).
- // TODO: Inline this factory when we start releasing Ivy compiled libraries (feature-libs/order/root/order-root.module.ts:L67-L67).
- // @ts-ignore: Deprecated methods will be removed with next major release e @deprecated: Method doesn't pass facade method's requirements (returns void or Observable) su getQueryParams (feature-

libs/order/root/facade/order-history.facade.ts:L21-L21, :L144-L148). L'implementazione restituisce sempre `null` (feature-libs/order/core/facade/order-history.service.ts:L220-L225).

- `As we know the cart is not anonymous (precondition checked), we can safely use the cartId, which is actually the cart.code.` (feature-libs/order/core/facade/order.service.ts:L38-L41): attenzione, la precondizione consente anche l'anonimo **con carrello guest** (:L107-L111).
- `// Wait for the cart entity to be fully removed from the store before proceeding with the reorder.` (feature-libs/order/core/facade/reorder-order.service.ts:L81-L82).
- `// TODO: for future releases, refactor this part to thrown errors` — errori inghiottiti in `loadOrderList` e nei servizi resi/replenishment (feature-libs/order/core/facade/order-history.service.ts:L126-L128).
- `As discussed, this calculation is moved to SPA side. The calculation and validation should be in backend facade layer. + // TODO: user current language` (feature-libs/order/components/amend-order/amend-order.service.ts:L119-L132).
- `the order code is not available in the route as long as we're inside a guard, hence we redirect to the common orders page.` (feature-libs/order/components/amend-order/cancellations/order-cancellation.guard.ts:L28-L30).
- `When "Order Return" feature is enabled, this component becomes one tab in TabParagraphContainerComponent.` (feature-libs/order/components/order-history/order-history.component.ts:L88-L91).
- `Converts 2021-10-15 to 2021-10-15T15:38:05-05:00` — JSDoc del serializer replenishment (feature-libs/order/occ/adapters/converters/occ-scheduled-replenishment-order-form-serializer.ts:L34-L38).
- `//guards: inherited from standard config,` — nel mapping v2 i guard non vengono ripetuti perché il merge della config li conserva (feature-libs/order/components/order-details/order-details.module.ts:L84-L84).
- `// Every request that doesn't specify fields should be set to DEFAULT` (feature-libs/pdf-invoices/components/invoices-list/invoices-list.component.ts:L149-L149).
- Typo nei nomi: costante `ClEAR_REPLENISHMENT_ORDER_DETAILS` con "l" minuscola (feature-libs/order/core/store/actions/replenishment-order-details.action.ts:L20-L21), file `reoder-layout.config.ts`, factory PDF chiamata `defaultRequestedDeliveryDateComponentsConfig` (feature-libs/pdf-invoices/root/pdf-invoices-root.module.ts:L14-L14), campo `orderAttachmentsConnector` in `OrderDocumentFlowService` (feature-libs/order/document-flow/core/services/order-document-flow.service.ts:L18-L36).

8. Extension point

COSA	COME	RIFERIMENTO	RICETTA
Sostituire la logica di una facade (es. place order con controlli extra)	Estendere il service concreto esportato da `@spartacus/order/core` e fornire `{ provide: OrderFacade, useClass: ... }` nel modulo lazy (accanto a `OrderModule`)	feature-libs/order/core/facade/facade-providers.ts:L26-L63; feature-libs/order/core/public_api.ts:L7-L12	50 — Ricette: configurazione, DI, interceptor, eventi
Reagire al place order / replenishment	`EventService.get(OrderPlacedEvent)` / `ReplenishmentOrderScheduledEvent`	feature-libs/order/root/events/order.events.ts:L14-L72; esempio feature-libs/checkout/base/root/events/checkout-place-order-event.listener.ts:L24-L40	50

COSA	COME	RIFERIMENTO	RICETTA
Cambiare chiamate HTTP	Fornire un adapter (`OrderHistoryAdapter`, `OrderAdapter`, …) o estendere un `Occ*Adapter` (metodi URL `protected`)	feature-libs/order/core/connectors/order-history.adapter.ts:L19-L112; feature-libs/order/occ/order-occ.module.ts:L38-L90	52 — Ricette: OCC, adapter, converter, endpoint
Arricchire i dati	Aggiungere un converter multi su `ORDER_NORMALIZER` & co. (alcuni token non hanno converter di default)	feature-libs/order/root/tokens/converters.ts:L24-L62; core-libs/core/src/util/converter.service.ts:L80-L88	52
Cambiare campi/endpoint	`provideConfig({ backend: { occ: { endpoints: { orderDetail: ... } } } })`	feature-libs/order/occ/config/default-occ-order-config.ts:L9-L50; feature-libs/order/occ/model/occ-order-endpoints.model.ts:L104-L106	52
Sostituire un componente CMS	`cmsComponents: { AccountOrderDetailsOverviewComponent: { component: ... } }` (i guard restano per merge)	feature-libs/order/components/order-details/order-details.module.ts:L128-L172	51 — Ricette: componenti CMS, outlet, route e layout
Riusare un componente di dettaglio con altra sorgente	`providers: [{ provide: OrderDetailsService, useExisting: ... }]` nel mapping CMS	feature-libs/order/components/order-confirmation/order-confirmation.module.ts:L96-L129	51
Inserire contenuto nelle consegne	Outlet `OrderOutlets.ORDER_CONSIGNMENT`, `CONSIGNMENT_DELIVERY_INFO`, `SERVICE_DETAILS`	feature-libs/order/root/model/order-outlets.model.ts:L10-L14	51
Logica di cancel/reso	Estendere `OrderAmendService` / `OrderCancellationService` / `OrderReturnService` e fornirli nel mapping	feature-libs/order/components/amend-order/amend-order.service.ts:L34-L153; feature-libs/order/components/amend-order/cancellations/cancel-order/cancel-order.module.ts:L38-L51	51
Visualizzazione delivery mode	Sostituire `OrderOverviewComponentService.shouldShowDeliveryMode`	feature-libs/order/components/order-details/order-overview/order-overview-component.service.ts:L10-L15	50
Rotte	Override di `routing.routes.orderDetails.paths` ecc.	feature-libs/order/root/config/default-order-routing-config.ts:L9-L54	51
Dialog	Override di `launch.REORDER` ecc. in `LayoutConfig`	feature-libs/order/components/order-details/reoder-layout.config.ts:L10-L18	51

COSA	COME	RIFERIMENTO	RICETTA
UI v2	`{ provide: USE_MY_ACCOUNT_V2_ORDER, useValue: true }`	feature-libs/order/root/tokens/context.ts:L17-L20; projects/storefrontapp/src/app/spartacus/features/order/order-feature.module.ts:L34-L37	53 — Ricette: feature lib lazy, carrello/checkout, stili, traduzioni
Traduzioni e stili	Chunk `order`, `myAccountV2Order`; scss `feature-libs/order/_index.scss`	feature-libs/order/assets/translations/translations.ts:L9-L42; feature-libs/order/_index.scss:L1-L5	53
Upgrade	Non usare simboli non esportati (`OccReorderOrderAdapter`, `OccReorderOrderNormalizer`, `ReturnRequestService` dei componenti, store interno)	feature-libs/order/occ/adapters/index.ts:L7-L12; feature-libs/order/core/public_api.ts:L7-L12	54 — API pubblica vs interna, upgrade

Avvertenze specifiche:

- Un override di facade va fornito **nel modulo lazy**: il proxy root risolve la facade con `injector.get(facadeClass)` sull'injector del modulo caricato (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L49-L52). Nell'app demo il punto naturale è `OrderWrapperModule` (projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L14-L27).
- Aggiungere un metodo a una facade richiede di aggiungerlo anche ai `methods` del factory, altrimenti il proxy non lo espone (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L117-L127).
- Lo store (actions, selectors, `order-state`) è esportato da `@spartacus/order/core`, ma effects e reducers no (feature-libs/order/core/public_api.ts:L7-L12).

---

9. Trappole, casi limite, comportamenti controintuitivi

1. **Refresh della conferma = ordine perso.** L'ordine piazzato vive solo nel `BehaviorSubject` (feature-libs/order/core/facade/order.service.ts:L24-L24): ricaricando `/order-confirmation` il servizio riparte vuoto e `OrderConfirmationGuard` reindirizza a `orders` (feature-libs/order/components/guards/order-confirmation.guard.ts:L27-L32).
2. **Il primo componente distrutto svuota l'ordine per tutti.** Tre componenti di conferma chiamano `clearPlacedOrder()` in `ngOnDestroy` (vedi §3.3, passo 12). `DA VERIFICARE`: la sequenza effettiva di distruzione a runtime e se qualche componente ancora vivo riceve `undefined` (nessun test eseguito, `node_modules` assente).
3. `placePaymentAuthorizedOrder` **con** `cartId` **esplicito** non usa il command (niente `CancelPrevious`) né controlla anonimo/guest (feature-libs/order/core/facade/order.service.ts:L127-L153).
4. **Il reorder cancella il carrello attivo** prima di creare quello nuovo (feature-libs/order/core/facade/reorder-order.service.ts:L67-L69, :L76-L80). Se la cancellazione fallisce: `'Failed to delete cart before reorder'`.
5. **Endpoint B2B-only.** `reorder` e `scheduleReplenishmentOrder` esistono solo in `defaultB2bOccConfig` (core-libs/setup/recipes/b2b/config/default-b2b-occ-config.ts:L31-L36). Senza, `OccEndpointsService.buildUrl` non lancia: ripiega sul **nome della chiave** come path (`|| endpoint`), quindi la richiesta parte verso `<baseUrl>/reorder?orderCode=...` e fallisce lato server (core-libs/core/src/occ/services/occ-endpoints.service.ts:L196-L224).

6. `getQueryParams` **assente dal proxy.** Non è nei `methods` di `OrderHistoryFacade` (feature-libs/order/root/facade/order-history.facade.ts:L24-L40); `OrderHistoryComponent.getQueryParams` lo chiama (feature-libs/order/components/order-history/order-history.component.ts:L131-L133). Funziona solo perché il componente vive nel modulo lazy e riceve il servizio reale, che restituisce `null`. DA VERIFICARE a runtime quale istanza riceve il componente (dedotto dal funzionamento degli injector dei moduli lazy, non osservato).
7. **Reset asimmetrici al cambio di contesto.** `resetUserOrders$` reagisce solo a `LANGUAGE_CHANGE` (feature-libs/order/core/store/effects/orders.effect.ts:L73-L73), `resetOrderDetails$` anche a `CURRENCY_CHANGE` (feature-libs/order/core/store/effects/order-details.effect.ts:L91-L94).
8. `forEach` **su undefined negli errori di cancel.** `error.error?.errors.forEach(...)` lancia se `error.error` esiste senza `errors` (feature-libs/order/core/store/effects/order-details.effect.ts:L69-L69; analogo feature-libs/order/core/store/effects/replenishment-order-details.effect.ts:L72-L72).
9. **Create e load del reso condividono la slice** `orderReturn` (feature-libs/order/core/store/reducers/index.ts:L53-L55): il "dettaglio" dopo la creazione è la risposta della create; `ReturnRequestService` ricarica solo se `rma` differisce (feature-libs/order/components/return-request-detail/return-request.service.ts:L48-L53).
10. **Cancel di un replenishment non in lista svuota la lista**: se l'indice è `-1` il reducer restituisce `initialState` (feature-libs/order/core/store/reducers/replenishment-orders.reducer.ts:L40-L42).
11. **N+1 richieste in My Account v2.** Un dettaglio per ogni ordine + un tracking per ogni consegna con `trackingID` (feature-libs/order/core/facade/my-account-v2-order-history.service.ts:L54-L67, :L100-L118).
12. **Emissioni ripetute v2.** In `getOrderHistoryList` lo `switchMap` restituisce un array (`orderHistory.orders.map(...)`), quindi emette lo stesso oggetto una volta per ordine (feature-libs/order/core/facade/my-account-v2-order-history.service.ts:L159-L167). `getOrderDetailsWithTracking` fa `push` sulle consegne dentro un `map`: emissioni ripetute del tracking possono duplicarle (feature-libs/order/core/facade/my-account-v2-order-history.service.ts:L52-L67) — DA VERIFICARE con un test.
13. **Reso abbinato per codice prodotto, non per** `entryNumber`: due entry dello stesso prodotto prendono la stessa `shippedQuantity`; le entry senza consegna spariscono (feature-libs/order/components/amend-order/returns/return-order/return-order.component.ts:L53-L71).
14. **La conferma reso non controlla** `form.valid`, a differenza della conferma cancel (feature-libs/order/components/amend-order/returns/return-order-confirmation/return-order-confirmation.component.ts:L47-L50, feature-libs/order/components/amend-order/cancellations/cancel-order-confirmation/cancel-order-confirmation.component.ts:L42-L48).
15. **Prezzo di amend formattato sempre con locale** `'en'` (feature-libs/order/components/amend-order/amend-order.service.ts:L129-L135).
16. **Refresh della conferma cancel/reso** → la guard trova il form vuoto e reindirizza a `orders` (feature-libs/order/components/amend-order/cancellations/order-cancellation.guard.ts:L24-L38, feature-libs/order/components/amend-order/returns/order-return.guard.ts:L24-L38).
17. `OrderDetailsService` **fuori dalla rotta di dettaglio**: è `providedIn: 'root'` e legge `params.orderCode`; se il param manca emette `undefined` e chiama `clearOrderDetails()` (feature-libs/order/components/order-details/order-details.service.ts:L30-L44). Il document flow lo riusa e quindi funziona solo sulla pagina di dettaglio (feature-libs/order/document-flow/components/order-document-flow/order-document-flow.component.ts:L29-L46).
18. **Document flow senza** `dependencies`, pur usando `OrderDetailsService` di `@spartacus/order/components` (feature-libs/order/document-flow/root/order-document-flow-root.module.ts:L13-L19).
19. `PDFInvoicesService` **legge** `userId` **una volta sola** nel costruttore: dopo login/logout resta il valore precedente se non si passa `userId` esplicito (feature-libs/pdf-invoices/core/services/pdf-invoices.

service.ts:L30-L34).

20. **Stream che muoiono dopo un errore.** `invoicesList$` chiude con `EMPTY` dopo un errore e i cambi successivi di pagina/sort non ricaricano (feature-libs/pdf-invoices/components/invoices-list/invoices-list.component.ts:L96-L117); analogo nel dialog del document flow (feature-libs/order/document-flow/components/order-document-flow-dialog/order-document-flow-dialog.component.ts:L92-L137).
21. **Object URL mai revocati** per fatture e allegati (feature-libs/pdf-invoices/components/invoices-list/invoices-list.component.ts:L177-L179, feature-libs/order/components/order-details/order-attachments/attachments-dialog/order-attachments-dialog.component.ts:L130-L145).
22. **Subscription non chiuse** in `MyAccountV2ConsignmentTrackingComponent` e `MyAccountV2OrderDetailsActionsComponent` (feature-libs/order/components/order-details/my-account-v2/consignment-tracking/my-account-v2-consignment-tracking.component.ts:L26-L33, feature-libs/order/components/order-details/my-account-v2/order-details-actions/my-account-v2-order-details-actions.component.ts:L26-L30).
23. `MyAccountV2OrdersComponent.getProduct` **con** `entries = []` accede a `order.entries[0].product` (feature-libs/order/components/my-account-v2/my-account-v2-orders.component.ts:L40-L49).
24. `ngAfterViewChecked` **con** `detectChanges()` **a ogni ciclo** in `MyAccountV2DownloadInvoicesComponent` (feature-libs/order/components/order-details/my-account-v2/download-invoices/my-account-v2-download-invoices.component.ts:L57-L65).
25. **Dialog cancel replenishment.** `onSuccess` chiama `clearCancelReplenishmentOrderProcessState()` anche quando il valore è `false` (feature-libs/order/components/replenishment-order-cancellation-dialog/replenishment-order-cancellation-dialog.component.ts:L88-L105).
26. **Rotte cancel/return senza** `AuthGuard` **di rotta**: la protezione è nel mapping CMS (feature-libs/order/root/order-root.module.ts:L104-L131, feature-libs/order/components/amend-order/cancellations/cancel-order/cancel-order.module.ts:L40-L42). Un mapping custom che dimentica `guards` lascia la pagina accessibile agli anonimi.
27. **Chiave entità vuota.** `LoadOrderByIdSuccess` usa `payload.code ?? ''` (feature-libs/order/core/store/actions/order-by-id.action.ts:L21-L36).
28. **Converter assenti di default.** Per `ORDER_HISTORY_NORMALIZER`, `CONSIGNMENT_TRACKING_NORMALIZER`, `ORDER_RETURNS_NORMALIZER`, `REPLENISHMENT_ORDER_HISTORY_NORMALIZER`, `ORDER_RETURN_REQUEST_INPUT_SERIALIZER` non è registrato nulla: `pipeable` passa lo stream invariato, e per il serializer dell'input del reso, applicato con `convert`, il payload viene inviato così com'è (feature-libs/order/occ/order-occ.module.ts:L63-L87, core-libs/core/src/util/converter.service.ts:L80-L88, :L106-L112, feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L140-L143). Il primo converter che aggiungete è l'unico.

---

10. Come fare debug

- **"Feature orderCore is not configured properly".** Il proxy lancia questo errore se nessuno ha fornito `featureModules.order.module` (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L43-L47). Verificare il modulo feature dell'app (projects/storefrontapp/src/app/spartacus/features/order/order-feature.module.ts:L26-L33).
- **Il modulo lazy non arriva.** Controllare nel tab Network il chunk del wrapper; la dipendenza `cartBase` viene risolta prima (feature-libs/order/root/order-root.module.ts:L71-L74, core-libs/core/src/lazy-loading/feature-modules.service.ts:L54-L68).

- **Redux DevTools.** Feature key `order`, 9 slice (§4.5). Azioni con prefisso `[Order] ...` (es. feature-libs/order/core/store/actions/orders.action.ts:L11-L14). Per cancel guardare `state.process` alle chiavi `cancelOrder`, `cancelReturn`, `cancelReplenishmentOrder`.
- **Dettaglio che non carica.** Verificare che `params.orderCode` sia presente (feature-libs/order/components/order-details/order-details.service.ts:L30-L33) e che qualcuno sia sottoscritto a `getOrderDetails()` (il caricamento è lazy, :L51-L55).
- **Lista vuota senza errori.** `loadOrderList` inghiotte l'errore di `takeUserId(true)` per l'anonimo (feature-libs/order/core/facade/order-history.service.ts:L103-L129); controllare lo stato di login. Se la slice `orders` ha già `error: true`, `getOrderHistoryList` non ritenta (:L76-L83) finché non arriva `clearOrderList()`.
- **Place order fallisce subito.** Messaggio `Checkout conditions not met`: manca userId/cartId o è un anonimo senza guest cart (feature-libs/order/core/facade/order.service.ts:L107-L112). Errori Jalo vengono ritentati da `backOff` prima di arrivare al chiamante (feature-libs/order/occ/adapters/occ-order.adapter.ts:L61-L63).
- **Reorder 404 / URL strano.** Se l'URL contiene `/reorder?orderCode=` senza `orgUsers`, manca la config B2B (Trappola 5).
- **URL del dettaglio con campi inattesi.** Con `showOrderQuoteLink: true` l'URL è il risultato della fusione degli scope (feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L212-L231): stampare `getOrderDetailUrl` in un adapter esteso.
- **Breakpoint utili:** `OrderService.checkoutPreconditions` (feature-libs/order/core/facade/order.service.ts:L99-L117), `OrderConfirmationGuard.canActivate` (feature-libs/order/components/guards/order-confirmation.guard.ts:L24-L36), `OrdersEffect.loadUserOrders$` (feature-libs/order/core/store/effects/orders.effect.ts:L38-L54), `OrderCancellationGuard` (feature-libs/order/components/amend-order/cancellations/order-cancellation.guard.ts:L24-L38), `ReorderOrderService.deleteCartAndWait` (feature-libs/order/core/facade/reorder-order.service.ts:L76-L92).
- **Eventi.** Sottoscrivere temporaneamente `EventService.get(OrderPlacedEvent)` per vedere `userId`, `cartId`, `cartCode`, `order` (feature-libs/order/root/events/order.events.ts:L14-L72).
- **Test.** La libreria ha una config Vitest (`feature-libs/order/vitest.config.ts`); vedi il capitolo 44.

---

11. Domande di autoverifica

1. **Perché `OrderRootModule` non basta da solo per usare `OrderFacade`?** Perché la feature è "configurata" solo se ha `module`, che il root module non fornisce; il proxy lancia `Feature ... is not configured properly`. — core-libs/core/src/lazy-loading/feature-modules.service.ts:L33-L35; core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L43-L47.
2. **Dove si trova l'ordine appena piazzato e cosa succede con un refresh della pagina di conferma?** In un `BehaviorSubject` di `OrderService`, non nello store; al refresh è vuoto e `OrderConfirmationGuard` reindirizza a `orders`. — feature-libs/order/core/facade/order.service.ts:L24-L24; feature-libs/order/components/guards/order-confirmation.guard.ts:L24-L36.
3. **Come fa `OrderOverviewComponent` a funzionare sia nel dettaglio ordine sia nella conferma?** Legge da `OrderDetailsService`; il mapping CMS della conferma fornisce `{ provide: OrderDetailsService, useExisting: OrderFacade }`, e il componente gestisce l'assenza di `isOrderDetailsLoading` con un controllo `typeof`. — feature-libs/order/components/order-confirmation/order-confirmation.module.ts:L96-L105; feature-libs/order/components/order-details/order-overview/order-overview.component.ts:L66-L70.

4. **Quando parte la richiesta della lista ordini?** Quando qualcuno si sottoscrive a `getOrderHistoryList` e la slice `orders` non è né loading né success né error. — `feature-libs/order/core/facade/order-history.service.ts:L71-L87`.
5. **Come vengono caricati gli ordini generati da un replenishment?** Lo stesso `OrderHistoryComponent` è montato nella pagina di dettaglio replenishment; `loadOrderList` legge `replenishmentOrderCode` dal router e `OrdersEffect` chiama `loadReplenishmentDetailsHistory`. — `feature-libs/order/core/facade/order-history.service.ts:L107-L123`; `feature-libs/order/core/store/effects/orders.effect.ts:L39-L47`.
6. **Cosa fa il reorder al carrello attivo dell'utente?** Lo cancella e aspetta che l'entità sia rimossa (o in errore) prima di chiamare il backend. — `feature-libs/order/core/facade/reorder-order.service.ts:L56-L92`.
7. **Perché un reorder in uno storefront B2C senza config B2B fallisce?** L'endpoint `reorder` non ha default nella libreria order; `buildUrl` ripiega sul nome della chiave come path. — `feature-libs/order/occ/model/occ-order-endpoints.model.ts:L86-L93`; `core-libs/core/src/occ/services/occ-endpoints.service.ts:L220-L224`.
8. **Come sa `OrderCancellationService.save` che la cancellazione è andata a buon fine?** Attende `getCancelOrderSuccess()` con `first(Boolean)`, che legge il process state `cancelOrder`. — `feature-libs/order/components/amend-order/cancellations/order-cancellation.service.ts:L75-L78`; `feature-libs/order/core/facade/order-history.service.ts:L191-L204`.
9. **Qual è la quantità massima selezionabile per il reso di una entry?** Il validatore del form usa `returnableQuantity` (o `quantity`) dell'entry originale (`buildForm` su `order.entries`, letto da `OrderDetailsService`). `ReturnOrderComponent` sostituisce `returnableQuantity` con la `shippedQuantity` della consignment entry con lo stesso codice prodotto solo nelle entry passate alla UI: il contatore e `[max]` usano quindi `shippedQuantity`, mentre `Validators.max` resta sul valore originale. — `feature-libs/order/components/amend-order/amend-order.service.ts:L68-L70`, `:L96-L106`, `:L140-L148`; `feature-libs/order/components/amend-order/returns/return-order/return-order.component.ts:L42-L73`; `feature-libs/order/components/amend-order/amend-order-items/amend-order-items.component.html:L127-L127`.
10. **Cosa cambia attivando `USE_MY_ACCOUNT_V2_ORDER`?** Mapping v2 per le azioni di dettaglio e per la storia ordini, e un `MODULE_INITIALIZER` che sostituisce il contenuto dell'outlet `ORDER_CONSIGNMENT` con il tracking v2. — `feature-libs/order/components/order-details/order-details.module.ts:L61-L87`, `:L180-L187`; `feature-libs/order/components/order-history/order-history.module.ts:L65-L77`.

1. A cosa serve e perché esiste

`@spartacus/organization` è la libreria B2B di Spartacus. Copre le funzioni che un acquirente aziendale si aspetta oltre al carrello e al checkout: amministrare la propria azienda (unità, utenti, gruppi di utenti, budget, cost center, limiti di acquisto), approvare ordini, vedere gli ordini dell'unità, consultare l'estratto conto e registrarsi come utente B2B. È divisa in cinque sotto-pacchetti, ciascuno con il proprio entry point `root` (eager) e il proprio modulo lazy:

SOTTO-PACCHETTO	FEATURE LAZY	COSA FA
`administration`	`organizationAdministration`	CRUD delle sei entità aziendali, in un framework condiviso list/form/card
`account-summary`	`organizationAccountSummary`	estratto conto per unità, documenti e download allegati
`order-approval`	`organizationOrderApproval`	dashboard e dettaglio delle approvazioni, decisione approva/rifiuta
`unit-order`	`organizationUnitOrder`	storico e dettaglio degli ordini a livello di unità
`user-registration`	`organizationUserRegistration`	form di richiesta account B2B (anche con OTP)

L'entry point principale `@spartacus/organization` riesporta soltanto `administration` (il JSDoc parla ancora di "my-account") — feature-libs/organization/public_api.ts:L7-L10. A margine c'è `core-libs/core/src/cost-center`, che in `@spartacus/core` contiene solo i token dei converter dei cost center e un modulo vuoto — core-libs/core/src/cost-center/connectors/cost-center/converters.ts:L12-L22, core-libs/core/src/cost-center/cost-center.module.ts:L9-L17.

Il pezzo più interessante dal punto di vista architetturale è `administration`. Ha sei entità con UI quasi identiche: una lista paginata, un pannello di dettaglio, un form di creazione/modifica, sotto-liste di relazioni "assegna/rimuovi". Spartacus non scrive sei volte lo stesso codice. Usa **un solo componente CMS generico per la lista** (`ListComponent`) e **due servizi astratti** (`ListService`, `ItemService`) che ogni entità implementa. Il componente CMS li riceve dai `providers` del mapping CMS. La navigazione fra lista, dettaglio e form non usa pagine CMS separate: sono **child route Angular** dichiarate nel mapping CMS (`childRoutes`) e aggiunte a runtime alla configurazione del router. Il risultato è una "split view" a pannelli annidati in cui ogni livello è un `<router-outlet>` — feature-libs/organization/administration/components/budget/budget.config.ts:L29-L81, core-libs/storefront/cms-structure/services/cms-routes-impl.service.ts:L69-L124.

Questo capitolo segue soprattutto il **budget** da capo a fondo (CMS → route → componenti → servizi → NgRx → OCC). Poi mostra come le altre entità e gli altri sotto-pacchetti riusano lo stesso schema o se ne discostano.

Prerequisiti utili: il caricamento lazy dei feature CMS (cap. 12), le `childRoutes` e le guardie dei componenti CMS (cap. 15, cap. 16), lo store con `StateUtils` (cap. 19), le facade lazy (cap. 20) e OCC (cap. 21).

2. Mappa dei file

PATH	RUOLO
`feature-libs/organization/public_api.ts`	entry `@spartacus/organization`: riesporta `administration`

PATH	RUOLO
feature-libs/organization/administration/administration.module.ts	AdministrationModule (lazy): AdministrationCoreModule.forRoot() + OCC + componenti

feature-libs/organization/vitest.config.ts	configurazione Vitest: molti alias verso helper di test di core/storefront, maxWorkers: 4, soglie coverage

3. Come funziona passo per passo

3.1 Wiring: root eager, feature lazy

L'app importa solo il **root module**. AdministrationRootModule fornisce con provideDefaultConfig la layout config, la UI config, la route semantica organization (path organization), le sei routing config delle entità e una factory che dichiara i CMS component del feature lazy — feature-libs/organization/administration/root/administration-root.module.ts:L44-L64. La factory associa al feature organizationAdministration (costante ORGANIZATION_ADMINISTRATION_FEATURE, feature-libs/organization/administration/root/feature-name.ts:L7-L7) i sei Manage*ListComponent. Quando uno di questi compare in una pagina CMS, il feature viene caricato — feature-libs/organization/administration/root/administration-root.module.ts:L24-L42.

La demo app collega il feature al codice reale. Importa AdministrationRootModule e registra module: () => import('./administration-wrapper.module'), più le traduzioni e i chunk i18n — projects/storefrontapp/src/app/spartacus/features/organization/organization-administration-feature.module.ts:L21-L47. Il wrapper importa AdministrationModule e, se environment.cdc è attivo, anche CdcAdministrationModule — projects/storefrontapp/src/app/spartacus/features/organization/administration-wrapper.module.ts:L12-L20. È questo il punto in cui le integrazioni (CDC) si agganciano al feature lazy.

AdministrationModule porta tre strati — feature-libs/organization/administration/administration.module.ts:L12-L19:

- **core** (AdministrationCoreModule.forRoot()): page meta, store, guard, due HttpErrorHandler multi (OrganizationConflictHandler, OrganizationBadRequestHandler) e, in forRoot(), i sei connector —

feature-libs/organization/administration/core/administration-core.module.ts:L21-L54;

- **OCC** (`AdministrationOccModule`): importa `CostCenterOccModule` di core, fornisce gli endpoint, lega gli adapter astratti alle classi `Occ*` con `useClass` e i converter con `useExisting` + `multi` — feature-libs/organization/administration/occ/administration-occ.module.ts:L58-L80;
- **componenti** (`AdministrationComponentsModule`): i sei moduli entità — feature-libs/organization/administration/components/administration-components.module.ts:L15-L25. Ognuno importa `SharedOrganizationModule` (cioè `ListModule`, `SubListModule`, `FormModule`) e fornisce come default la propria CMS config e la table config — feature-libs/organization/administration/components/budget/budget-components.module.ts:L18-L30, feature-libs/organization/administration/components/shared/shared-organization.module.ts:L12-L15.

Gli altri quattro sotto-pacchetti seguono lo stesso schema root/lazy. Le eccezioni sono annotate nelle sezioni 3.11-3.14.

3.2 Routing semantico e parametri

I nomi dei parametri di route stanno tutti in `ROUTE_PARAMS`. Attenzione all'indirizzo: la chiave è `addressCode` ma il valore è `'addressId'` — feature-libs/organization/administration/root/route-params.ts:L10-L18. Ogni entità ha una routing config che definisce le route semantiche e il `paramsMapping`, cioè quale proprietà del modello riempie il parametro. Per il budget le route sono `orgBudget`, `orgBudgetCreate`, `orgBudgetDetails`, `orgBudgetCostCenters`, `orgBudgetEdit`, con `budgetCode → code` — feature-libs/organization/administration/root/config/default-budget-routing.config.ts:L10-L38.

Le chiavi dei modelli non sono uniformi, e il `paramsMapping` è il punto in cui questa differenza viene assorbita:

ENTITÀ	PARAMETRO	PROPRIETÀ	RIFERIMENTO
Budget	`budgetCode`	`code`	feature-libs/organization/administration/root/config/default-budget-routing.config.ts:L10-L13
Unità	`unitCode` / `addressId` / `userCode`	`uid` / `id` / `customerId`	feature-libs/organization/administration/root/config/default-units-routing.config.ts:L10-L15
Utente	`userCode`	`customerId`	feature-libs/organization/administration/root/config/default-user-routing.config.ts:L10-L13
Gruppo utenti	`userGroupCode`	`uid`	feature-libs/organization/administration/root/config/default-user-group-routing.config.ts:L10-L13
Permesso	`permissionCode`	`code` (path `organization/purchase-limits`)	feature-libs/organization/administration/root/config/default-permission-routing.config.ts:L10-L13

La route della lista unità si chiama `orgUnits` (al plurale). Tutte le altre route delle unità hanno il prefisso `orgUnit` — feature-libs/organization/administration/root/config/default-units-routing.config.ts:L20-L29. Su questo torneremo nelle trappole.

Per la meccanica di `paramsMapping` e della risoluzione `{ cxRoute, params } | cxUrl` vedi il cap. 14.

3.3 Il mapping CMS: un componente generico, provider specifici, child route

Il cuore dell'architettura è nella CMS config di ogni entità. Per il budget, `ManageBudgetsListComponent` è mappato sul generico `ListComponent`. Il mapping sostituisce `ListService` e `ItemService` con `useExisting` verso `BudgetListService` e `BudgetItemService` — feature-libs/organization/administration/components/budget/budget.config.ts:L29-L42. Usa poi tre proprietà di `CmsComponentMapping` (`providers`, `childRoutes`, `guards`) — core-libs/core/src/cms/config/cms-config.ts:L60-L77:

- `childRoutes.parent.data.cxPageMeta`: il breadcrumb `orgBudget.breadcrumbs.list` e il resolver `BudgetRoutePageMetaResolver`;
- `childRoutes.children`: `create` → `BudgetFormComponent`, `:budgetCode` → `BudgetDetailsComponent` con i figli `edit` e `cost-centers` — feature-libs/organization/administration/components/budget/budget.config.ts:L43-L77;
- `guards: [AuthGuard, AdminGuard]` — feature-libs/organization/administration/components/budget/budget.config.ts:L78-L78.

Le sotto-relazioni "assign" seguono un pattern fisso: una route (es. `budgets` sotto un cost center) con due figli, `''` per la lista degli assegnati e `'assign'` per la lista degli assegnabili — feature-libs/organization/administration/components/cost-center/cost-center.config.ts:L70-L83. Le unità sono l'eccezione principale. Usano un `UnitListComponent` specifico (l'albero) e applicano `canActivate: [OrgUnitGuard]` a `create`, `edit` e `children`, e `[UserGuard]` a `users/create` e `users/:userCode/roles` — feature-libs/organization/administration/components/unit/units.config.ts:L53-L138. Gli utenti applicano `UserGuard` a `create`, `edit` e `change-password` — feature-libs/organization/administration/components/user/user.config.ts:L66-L85.

3.4 Dal CMS al router: guardie dei componenti e child route a runtime

Alla prima apertura di `/organization/budgets`, il guard della pagina CMS fa tre cose in ordine — core-libs/storefront/cms-structure/guards/cms-page-guard.service.ts:L65-L99:

1. **Risolve i mapping** dei componenti della pagina (`determineMappings`). È qui che il feature lazy `organizationAdministration` viene caricato, perché la pagina contiene `ManageBudgetsListComponent`.
2. **Esegue le guardie dei componenti**. `CmsGuardsService.cmsPageCanActivate` raccoglie le classi da tutti i mapping (deduplicate con un `Set`), le istanzia attraverso `UnifiedInjector` e le compone con `GuardsComposer` — core-libs/storefront/cms-structure/services/cms-guards.service.ts:L36-L48, core-libs/storefront/cms-structure/services/cms-components.service.ts:L253-L261. Passare dallo `UnifiedInjector` è ciò che permette di trovare `AdminGuard`, che non è `providedIn: 'root'` ma vive nel child injector del modulo lazy (sez. 3.10).
3. **Se l'esito è** `true` e la route non ha già `cxCmsRouteContext`, chiama `CmsRoutesImplService.handleCmsRoutesInGuard`.

`handleCmsRoutesInGuard` controlla se esiste già una route per la label della pagina. Se non esiste, legge le `childRoutes` dei componenti e, quando ci sono figli, chiama `updateRouting`. Poi rinaviga all'URL corrente con `navigateByUrl` e ritorna `false` per annullare la navigazione in corso — core-libs/storefront/cms-structure/services/cms-routes-impl.service.ts:L69-L91. `updateRouting` agisce solo per **content page** con label che inizia con `/` (es. `/organization/budgets`). Crea una route `path: label.substring(1)` con `PageLayoutComponent` e i figli (le guardie avvolte ricorsivamente), unisce `parent.data` con `cxCmsRouteContext` e fa `router.resetConfig([newRoute, ...config])` — core-libs/storefront/cms-structure/services/cms-routes-impl.service.ts:L93-L124. La seconda navigazione trova `cxCmsRouteContext` nei data della route e salta questo passo — core-libs/storefront/cms-structure/guards/cms-page-guard.service.ts:L88-L88.

Da questo momento `organization/budgets/create`, `organization/budgets/:budgetCode`, `.../edit`, `.../cost-centers` sono route Angular "vere". Vengono rese nei `<router-outlet>` annidati della lista e delle card (sez. 3.6).

3.5 Le guardie di accesso

`AdminGuard` attende da `UserAccountFacade.get()` un utente non vuoto, legge `roles` e richiede `B2BUserRole.ADMIN` (`'b2badmingroup'`). Senza il ruolo naviga alla route `organization` e mostra un warning `organization.notification.noSufficientPermissions`. Un commento lo dichiara una soluzione temporanea, in attesa dei

permessi lato backend — feature-libs/organization/administration/core/guards/admin.guard.ts:L27-L49. I valori dei ruoli B2B sono b2badmingroup, b2bcustomergroup, b2bmanagergroup, b2bapprovergroup, e il diritto UNITORDERVIEWER vale unitorderviewergroup — core-libs/core/src/model/org-unit.model.ts:L18-L27.

OrgUnitGuard e UserGuard delegano a OrgUnitService.isUpdatingUnitAllowed() e B2BUserService.isUpdatingUserAllowed(). Se ricevono false mostrano un warning e ritornano un UrlTree verso organization — feature-libs/organization/administration/core/guards/org-unit.guard.ts:L25-L37. Nel core entrambi i metodi ritornano sempre true: sono hook da sovrascrivere, ad esempio nelle integrazioni — feature-libs/organization/administration/core/services/org-unit.service.ts:L501-L503, feature-libs/organization/administration/core/services/b2b-user.service.ts:L414-L416.

3.6 La lista: `ListComponent` + `ListService`

ListComponent (cx-org-list) inietta ListService e ItemService, che il mapping CMS ha risolto nelle implementazioni del budget, e attiva gli stili della feature a11yNavigationChevronContrast — feature-libs/organization/administration/components/shared/list/list.component.ts:L109-L114. Il viewType del servizio diventa la classe host — feature-libs/organization/administration/components/shared/list/list.component.ts:L116-L117.

ListService<T, P> è astratto — feature-libs/organization/administration/components/shared/list/list.service.ts:L42-L51:

- **struttura tabella**: il default è VERTICAL_STACKED, e VERTICAL da lg in su. getStructure() delega a TableService.buildStructure(viewType, defaultTableStructure) — feature-libs/organization/administration/components/shared/list/list.service.ts:L137-L142. Quest'ultimo usa la TableConfig se esiste per quel tipo, altrimenti costruisce una struttura "random" — core-libs/storefront/shared/components/table/table.service.ts:L49-L58;
- **paginazione**: un BehaviorSubject che parte da pageSize: 10. La config è iniettata come OrganizationUIConfig — feature-libs/organization/administration/components/shared/list/list.service.ts:L91-L97;
- **getData()**: unisce pagination$ con l'eventuale options.pagination della struttura, chiama load() ed emette prima i **ghost data** con startWith — feature-libs/organization/administration/components/shared/list/list.service.ts:L117-L129. I ghost data sono un array di 10 elementi vuoti che serve allo skeleton di caricamento — feature-libs/organization/administration/components/shared/list/list.service.ts:L53-L59. hasGhostData li riconosce per identità — feature-libs/organization/administration/components/shared/list/list.service.ts:L147-L170;
- **navigazione**: view() emette una nuova paginazione con currentPage, sort() torna a pagina 0 — feature-libs/organization/administration/components/shared/list/list.service.ts:L147-L170;
- **chiave**: key() vale 'code' di default — feature-libs/organization/administration/components/shared/list/list.service.ts:L103-L105. Gli utenti la ridefiniscono in customerId — feature-libs/organization/administration/components/user/services/user-list.service.ts:L52-L95;
- **viewType/domainType**: tableType (astratto, con il TODO "rename to viewType") è esposto come viewType. domainType vale _domainType se impostato, altrimenti viewType — feature-libs/organization/administration/components/shared/list/list.service.ts:L63-L83. viewType sceglie la table config, domainType è la root i18n delle celle;
- **bottone di creazione**: di default è un link (CreateButtonType.LINK) con label organization.add, e onCreateButtonClick è vuoto — feature-libs/organization/administration/components/shared/list/list.service.ts:L20-L23, feature-libs/organization/administration/components/shared/list/list.service.ts:L184-L198;

- **ricerca**: disabilitata di default. Il minimo di caratteri viene da `organizationUI.listSearch.minCharacters`, con fallback 3. `search()` aggiunge `query` e azzera `currentPage` — feature-libs/organization/administration/components/shared/list/list.service.ts:L204-L242.

Il template della lista sta dentro `cx-split-view [hideMode]="false"`. Il titolo è `viewType + '.header'` e un `<router-outlet>` in fondo ospita le split view annidate delle child route — feature-libs/organization/administration/components/shared/list/list.component.html:L1-L21, feature-libs/organization/administration/components/shared/list/list.component.html:L208-L211. Il link "create" punta a `{ cxRoute: structure.type + 'Create' }` ed è disattivato finché ci sono ghost data — feature-libs/organization/administration/components/shared/list/list.component.html:L128-L140. La tabella evidenzia l'item corrente confrontando `key` con `currentKey$` e usa `domainType` come `i18nRoot` — feature-libs/organization/administration/components/shared/list/list.component.html:L165-L173.

Due dettagli di UX nel componente:

- la ricerca ha `debounceTime(300)`, accetta query lunghe almeno il minimo (o vuote) e scarta le query invariate — feature-libs/organization/administration/components/shared/list/list.component.ts:L84-L98;
- `listData$` tiene in cache i valori dell'ultimo caricamento reale, per mostrare una tabella semitrasparente durante i caricamenti successivi invece dello skeleton — feature-libs/organization/administration/components/shared/list/list.component.ts:L159-L187.

Il click su una riga va a `launchItem`, che delega a `ItemService.launchDetails` — feature-libs/organization/administration/components/shared/list/list.component.ts:L212-L226.

3.7 L'item corrente: `CurrentItemService` + `ItemService`

`CurrentItemService<T>` ricava la **chiave** dell'item dai parametri di route (inclusi quelli delle child route), con la chiave di parametro fornita dalla sottoclasse (`getParamKey()`) e `distinctUntilChanged` — feature-libs/organization/administration/components/shared/current-item.service.ts:L18-L33. `item$` carica l'item con `getItem(code)` solo se la chiave c'è, altrimenti emette `undefined` — feature-libs/organization/administration/components/shared/current-item.service.ts:L40-L42. `b2bUnit$` legge sempre `ROUTE_PARAMS.unitCode`, qualunque sia l'entità — feature-libs/organization/administration/components/shared/current-item.service.ts:L47-L50. Le sottoclassi implementano `getParamKey`, `getItem` e `getError` — feature-libs/organization/administration/components/shared/current-item.service.ts:L56-L69. Per il budget: parametro `budgetCode`, item da `BudgetService.get`, errore da `getErrorState` — feature-libs/organization/administration/components/budget/services/current-budget.service.ts:L20-L42.

`ItemService<T>` ("Provides CRUD operations for all organization entities") riespone `key$`, `current$`, `unit$` ed `error$` da `CurrentItemService` — feature-libs/organization/administration/components/shared/item.service.ts:L17-L45. Aggiunge:

- `save(form, key?)`: con form invalido marca tutto come touched, aggiorna ricorsivamente la validità e ritorna `EMPTY`. Con form valido **salva** `form.value` **prima di** `form.disable()`, perché la disabilitazione in alcuni casi lo svuota, poi chiama `update(key, value)` se c'è una key, altrimenti `create(value)` — feature-libs/organization/administration/components/shared/item.service.ts:L47-L65;
- i metodi astratti `load`, `create` (protected), `update` e `getDetailsRoute` (protected). `delete` è opzionale — feature-libs/organization/administration/components/shared/item.service.ts:L70-L92;
- `launchDetails(item)`: naviga con `RoutingService.go({ cxRoute, params })` solo se la route esiste e l'item ha almeno una proprietà. I `params` sono di default l'item stesso (`buildRouteParams`) — feature-libs/organization/administration/components/shared/item.service.ts:L101-L120;
- `setEditMode()`, che alimenta il `BehaviorSubject` `isInEditMode$` — feature-libs/organization/administration/components/shared/item.service.ts:L126-L131.

`BudgetItemService.load` forza un nuovo caricamento a ogni chiamata ("to ensure accurate data") e poi ritorna `get(code)` — feature-libs/organization/administration/components/budget/services/budget-item.service.ts:L32-L41. `update`/`create` fanno dispatch e ritornano `getLoadingStatus(value.code ?? '')`, cioè lo stato dell'entità identificata dal codice **nel valore inviato** e non dalla key di route — feature-libs/organization/administration/components/budget/services/budget-item.service.ts:L43-L54. La route di dettaglio è `orgBudgetDetails`, anche se il JSDoc dice ancora `'budgetDetails'` — feature-libs/organization/administration/components/budget/services/budget-item.service.ts:L56-L62.

Il dettaglio (`BudgetDetailsComponent`) costruisce `model$` in `ngOnInit` da `key$ → itemService.load(code)` con `startWith({})` — feature-libs/organization/administration/components/budget/details/budget-details.component.ts:L48-L59. Il template disabilita "edit" se il budget non è attivo o se si è già in edit mode. Include `cx-org-toggle-status` e `cx-org-disable-info` e linka la sotto-lista `orgBudgetCostCenters` — feature-libs/organization/administration/components/budget/details/budget-details.component.html:L6-L17, feature-libs/organization/administration/components/budget/details/budget-details.component.html:L81-L89.

3.8 Il form: `FormService` + `FormComponent`

`FormService<T>` costruisce il form **una sola volta** (`build`) e poi lo riusa. Se il form esiste e c'è un item, fa solo `patchData`. Altrimenti esegue `reset()`, `enable()` e patch, perché "while we should be able to reset with initial value, this doesn't always work" — feature-libs/organization/administration/components/shared/form/form.service.ts:L20-L37. `patchData` disabilita il form se `active === false`, lo riabilita se `active === true` e applica `{...defaultValue, ...item}` — feature-libs/organization/administration/components/shared/form/form.service.ts:L39-L51.

`BudgetFormService.build` crea questi controlli — feature-libs/organization/administration/components/budget/form/budget-form.service.ts:L26-L80:

- `code`: obbligatorio, senza caratteri speciali;
- `name`;
- `startDate` / `endDate`, nel formato del date picker;
- `budget`, che deve essere positivo;
- i sotto-gruppi `currency.isocode` e `orgUnit.uid`;
- un validatore `dateRange` sull'intero gruppo.

Il nome genera il codice al `blur` tramite `createCodeWithName` — feature-libs/organization/administration/components/budget/form/budget-form.component.html:L9-L15. La generazione avviene solo se il codice è vuoto: spazi → `-`, tutto in minuscolo — feature-libs/organization/administration/components/shared/utility/entity-code.ts:L9-L17. `BudgetFormComponent` fornisce localmente `ItemService → BudgetItemService` e `CurrentItemService → CurrentBudgetService`, preseleziona unità e valuta se ce n'è una sola e in `ngOnInit` chiama `unitService.loadList()` — feature-libs/organization/administration/components/budget/form/budget-form.component.ts:L42-L95.

`FormComponent` (`cx-org-form`) deriva `form$` da `itemService.current$`. Senza item passa `{}` a `getForm` ("we trick the form builder...") — feature-libs/organization/administration/components/shared/form/form.component.ts:L65-L75. `disabled$` osserva `statusChanges` e vale `true` sullo stato `'DISABLED'` — feature-libs/organization/administration/components/shared/form/form.component.ts:L28-L83. La chiave i18n è `i18nRoot + '.edit'` oppure `'.create'`. `ngOnInit`/`ngOnDestroy` accendono e spengono l'edit mode — feature-libs/organization/administration/components/shared/form/form.component.ts:L125-L142. `save()` prende la key corrente, chiama `itemService.save` e su `LoadStatus.SUCCESS` va al dettaglio e notifica `${i18nRoot}.messages.create|update`. **In ogni caso** riabilita il form — feature-libs/organization/administration/components/shared/form/form.component.ts:L90-L123. Il template avvolge una `cx-org-card` con

`cxOrgItemActive`. Il bottone Save è disabilitato da `form.disabled || disabled$`, e il Cancel sfrutta il soft-close della split view — `feature-libs/organization/administration/components/shared/form/form.component.html:L1-L30`.

3.9 Card, messaggi, toggle-status, sotto-liste

Card. `CardComponent` (`cx-org-card`) fornisce **a livello di componente** il proprio `MessageService` e legge l'item da `itemService.current$` — `feature-libs/organization/administration/components/shared/card/card.component.ts:L29-L59`. Quando cambia l'item svuota i messaggi, confrontando `code`, `uid` o `customerId` — `feature-libs/organization/administration/components/shared/card/card.component.ts:L88-L98`. `closeView` chiude a mano la view (`view.toggle(true)`) e dopo 500 ms simula il click sul parent. Senza questo accorgimento la chiusura del router outlet sarebbe immediata e taglierebbe l'animazione — `feature-libs/organization/administration/components/shared/card/card.component.ts:L68-L82`. Il template ha tre slot di proiezione (`[actions]`, `[info]`, `[main]`), un `cx-org-message` con `aria-live="assertive"` e un `<router-outlet>` dopo la view per il livello successivo della split view — `feature-libs/organization/administration/components/shared/card/card.component.html:L36-L63`.

Poiché il `MessageService` è nei `providers` (non nei `viewProviders`), è visibile anche al contenuto proiettato. In Angular i `providers` di un componente sono accessibili al template **e** al contenuto `ng-content`, mentre i `viewProviders` arrivano solo al template — `angular:adev/src/content/guide/di/debugging-and-troubleshooting-di.md:L279-L287`, `angular:packages/core/src/render3/di.ts:L685-L704`. Per questo `cx-org-toggle-status`, proiettato in `[actions]` dal template di dettaglio, scrive nella stessa area messaggi della card.

Messaggi. `MessageService` è `@Injectable()` senza `providedIn`. `add()` unisce i default, crea un `Subject` di eventi e lo restituisce. I messaggi info senza timeout ricevono 3000 ms — `feature-libs/organization/administration/components/shared/message/services/message.service.ts:L12-L51`. `MessageComponent` crea il componente del messaggio in un `ViewContainerRef` figlio, con un injector che fornisce `MessageData` — `feature-libs/organization/administration/components/shared/message/message.component.ts:L30-L58`. La chiusura avviene in due fasi: prima la classe `terminated` per l'animazione CSS, poi `destroy()` dopo 500 ms — `feature-libs/organization/administration/components/shared/message/message.component.ts:L68-L79`. L'auto-hide gira solo nel browser — `feature-libs/organization/administration/components/shared/message/base-message.component.ts:L68-L75`.

Toggle status. La disattivazione chiede conferma con un `ConfirmationMessageComponent` nel `MessageService` della card, l'attivazione no — `feature-libs/organization/administration/components/shared/detail/toggle-status-action/toggle-status.component.ts:L70-L105`. `confirm()` emette `{ confirm: true }` sugli eventi del messaggio — `feature-libs/organization/administration/components/shared/message/confirmation/confirmation-message.component.ts:L55-L63`. L'aggiornamento invia a `itemService.update` solo un patch `{ [key]: valore, active: !active }` — `feature-libs/organization/administration/components/shared/detail/toggle-status-action/toggle-status.component.ts:L118-L138`. Se l'input `disabled` è valorizzato, è lui a decidere (anche con `false`). Altrimenti il toggle è bloccato quando il parent è disabilitato o l'item è la root unit — `feature-libs/organization/administration/components/shared/detail/toggle-status-action/toggle-status.component.ts:L110-L116`. La root unit si riconosce per esclusione: ha `uid` e `name`, non ha `orgUnit`/`unit`, e non ha `parentOrgUnit` oppure ce l'ha uguale al proprio `uid` — `feature-libs/organization/administration/components/shared/detail/disable-info/disable-info.service.ts:L19-L34`. Quando l'item corrente passa a `active === false`, `ItemActiveDirective` mostra `organization.notification.disabled` — `feature-libs/organization/administration/components/shared/item-active.directive.ts:L26-L47`. `ItemExistsDirective` mostra `organization.notification.notExist` quando `error$` emette `true` — `feature-libs/organization/administration/components/shared/item-exists.directive.ts:L24-L37`.

Solo `UserGroupItemService` e `UnitAddressItemService` implementano `delete`. Le altre entità si "eliminano" disattivandole — `feature-libs/organization/administration/components/user-group/services/user-group-`

item.service.ts:L45-L47, feature-libs/organization/administration/components/unit/links/addresses/services/unit-address-item.service.ts:L74-L74. DeleteItemComponent chiede conferma e chiama l'opzionale itemService.delete?.(...) — feature-libs/organization/administration/components/shared/detail/delete-item-action/delete-item.component.ts:L97-L117.

Sotto-liste. SubListService estende ListService. Usa il solo layout VERTICAL, ghost data di 3 righe, e assign/unassign opzionali che di default ritornano EMPTY (con un TODO "abstract") — feature-libs/organization/administration/components/shared/sub-list/sub-list.service.ts:L18-L44. filterSelected filtra lato client perché "we can't filter with the backend API" — feature-libs/organization/administration/components/shared/sub-list/sub-list.service.ts:L46-L63. SubListComponent estende ListComponent e ricarica con service.getData(key) a ogni cambio di key — feature-libs/organization/administration/components/shared/sub-list/sub-list.component.ts:L43-L69. Il suo template rende una cx-org-card con i18nRoot = viewType e mostra la paginazione solo con totalPages > 1 — feature-libs/organization/administration/components/shared/sub-list/sub-list.component.html:L1-L5, feature-libs/organization/administration/components/shared/sub-list/sub-list.component.html:L23-L35. AssignCellComponent.toggleAssign chiama assign/unassign(key, link) e notifica ${viewType}.assigned|unassigned. Il link è code ?? customerId ?? uid del contesto della riga, perché "the object do not have a normalized shape" — feature-libs/organization/administration/components/shared/sub-list/assign-cell.component.ts:L50-L109.

Celle. CellComponent legge il contesto dall'outlet. Con il toggle a11yCardNotificationMessage si sottoscrive a outlet.context$ e chiama markForCheck — feature-libs/organization/administration/components/shared/table/cell.component.ts:L31-L47. Una cella è linkabile solo se la proprietà è definita e cellOptions.linkable è true. La route generata è _type + 'Details' — feature-libs/organization/administration/components/shared/table/cell.component.ts:L69-L87. Le sottoclassi sono piccole: ActiveLinkCellComponent cambia solo tabIndex — feature-libs/organization/administration/components/shared/table/active-link/active-link-cell.component.ts:L19-L23; AmountCellComponent mostra budget + ' ' + currency — feature-libs/organization/administration/components/shared/table/amount/amount-cell.component.ts:L19-L33.

3.10 Core: NgRx, servizi-facade, esito delle operazioni

Store. OrganizationStoreModule registra la feature NgRx organization con reducer da token, metaReducers ed effects — feature-libs/organization/administration/core/store/organization-store.module.ts:L14-L23. Lo stato ha sei slice (budget, orgUnit, userGroup, permission, costCenter, b2bUser) — feature-libs/organization/administration/core/store/organization-state.ts:L103-L114. Ognuna è un combineReducers di entityLoaderReducer (entities, list e le liste di relazione) — feature-libs/organization/administration/core/store/reducers/index.ts:L94-L105. Il meta-reducer clearOrganizationState azzera **l'intero** stato organization su CLEAR_ORGANIZATION_DATA, AuthActions.LOGOUT e SiteContextActions.LANGUAGE_CHANGE — feature-libs/organization/administration/core/store/reducers/index.ts:L209-L227.

Azioni ed effects. Le azioni budget estendono le StateUtils.Entity*Action. LoadBudgets usa come id dell'entità lista la serializeSearchConfig(params) — feature-libs/organization/administration/core/store/actions/budget.action.ts:L64-L75. LoadBudgetSuccess usa i code come id — feature-libs/organization/administration/core/store/actions/budget.action.ts:L51-L62. UpdateBudget marca in loading payload.budget.code, non payload.budgetCode — feature-libs/organization/administration/core/store/actions/budget.action.ts:L132-L140. loadBudgets$ normalizza la pagina con StateUtils.normalizeListPage(budgets, 'code') ed emette sia le entità sia la pagina — feature-libs/organization/administration/core/store/effects/budget.effect.ts:L58-L72. createBudget$ e updateBudget$ emettono OrganizationClearData sia in successo sia in errore — feature-libs/organization/administration/core/store/effects/budget.effect.ts:L94-L109, feature-libs/organization/administration/core/store/effects/budget.effect.ts:L122-L139. Gli errori passano da tryNormalizeHttpError — feature-libs/organization/administration/core/store/effects/budget.effect.ts:L37-L44.

Servizi. `BudgetService` è `providedIn: 'root'`. I comandi ottengono lo userId con `takeUserId(true)` e fanno dispatch. Il ramo d'errore è vuoto, con un TODO — feature-libs/organization/administration/core/services/budget.service.ts:L28-L45. Le query usano due schemi diversi:

- `get(code)` usa `using()`: una sottoscrizione collaterale a `loading$` (con `auditTime(0)`) innesca `loadBudget` se lo stato non è né loading né success né error. Il valore emesso è `getBudgetValue` filtrato sui valori truthy — feature-libs/organization/administration/core/services/budget.service.ts:L63-L89;
- `getList(params)` usa `observeOn(queueScheduler)`, innesca il load se serve ed emette solo a stato success o error — feature-libs/organization/administration/core/services/budget.service.ts:L91-L104.

`getCostCenters(code)` non fa chiamate dedicate: legge i `costCenters` annidati nel budget — feature-libs/organization/administration/core/services/budget.service.ts:L106-L115.

Esito. `getItemStatus` osserva lo stato dell'entità con `pairwise()` e produce un risultato solo per la transizione **da** `loading` **a uno stato successivo**: `SUCCESS`, `ERROR` o `null` — feature-libs/organization/administration/core/utils/get-item-status.ts:L15-L31. `LoadStatus` è un enum numerico (`SUCCESS = 0`, `ERROR = 1`) — feature-libs/organization/administration/core/model/organization-item-status.ts:L7-L15. È questo meccanismo che collega un dispatch "fire-and-forget" alla UI che aspetta un esito.

Nel create l'ordine delle azioni è `CreateBudgetSuccess` seguito da `OrganizationClearData` — feature-libs/organization/administration/core/store/effects/budget.effect.ts:L96-L99. `getItemStatus` vede quindi prima la coppia (loading, success) ed emette `SUCCESS`. Il reset successivo produce una coppia con stato precedente non-loading, che viene filtrata. `FormComponent` comunque prende solo il primo esito (`take(1)`) — feature-libs/organization/administration/components/shared/form/form.component.ts:L95-L96.

Selettori, connector, guardie. I selector partono da `createFeatureSelector('organization')`. La lista viene denormalizzata con `StateUtils.denormalizeSearch` — feature-libs/organization/administration/core/store/selectors/budget.selector.ts:L51-L59, feature-libs/organization/administration/core/store/selectors/feature.selector.ts:L14-L17. `BudgetConnector` delega 1:1 all'astratto `BudgetAdapter` — feature-libs/organization/administration/core/connectors/budget/budget.connector.ts:L13-L41, feature-libs/organization/administration/core/connectors/budget/budget.adapter.ts:L11-L34. Le guardie sono fornite da `OrganizationsGuardsModule` nel child injector del modulo lazy, apposta per permetterne l'override da altre librerie o dall'app — feature-libs/organization/administration/core/guards/organization-guards.module.ts:L12-L21. Il core aumenta inoltre via module augmentation i tipi `B2BUnit`, `B2BUser` e `CostCenter` di `@spartacus/core` — feature-libs/organization/administration/core/model/augmented-core.model.ts:L9-L33.

Errori HTTP. `OrganizationConflictHandler` gestisce i 409 con errori `AlreadyExistsError`: confronta il messaggio con regex per budget, user, userGroup, unit e cost center e mostra `organization.httpHandlers.conflict.<key>` — feature-libs/organization/administration/core/http-interceptors/conflict/conflict.handler.ts:L20-L92. Il suo `hasMatch` richiede sia lo status sia una regex corrispondente, così le altre risposte 409 non vengono intercettate — feature-libs/organization/administration/core/http-interceptors/conflict/conflict.handler.ts:L29-L31. `OrganizationBadRequestHandler` fa lo stesso con i 400 `ModelSavingError`/`DuplicateUidError` — feature-libs/organization/administration/core/http-interceptors/bad-request/bad-request.handler.ts:L20-L29, feature-libs/organization/administration/core/http-interceptors/bad-request/bad-request.handler.ts:L84-L89. Per la catena `HttpErrorHandler` vedi il cap. 41.

Page meta. `OrganizationPageMetaResolver` si applica a `CompanyPageTemplate` (content page) — feature-libs/organization/administration/core/services/organization-page-meta.module.ts:L11-L20, feature-libs/organization/administration/core/services/organization-page-meta.resolver.ts:L41-L50. Inserisce il breadcrumb "Organization" dopo "home", tranne quando la route corrente è proprio `organization` — feature-libs/organization/administration/core/services/organization-page-meta.resolver.ts:L99-L130.

Il layout di `CompanyPageTemplate` ha il solo slot `BodyContent` — `feature-libs/organization/administration/root/config/default-organization-layout.config.ts:L9-L15`.

3.11 OCC

Gli endpoint budget sono `/users/${userId}/budgets` e `/users/${userId}/budgets/${budgetCode}`. Quelli dei cost center non contengono lo `userId` (`/costcenters`, `/costcentersall`) — `feature-libs/organization/administration/occ/config/default-occ-organization-config.ts:L13-L53`. `OccBudgetAdapter` usa questi metodi HTTP — `feature-libs/organization/administration/occ/adapters/occ-budget.adapter.ts:L33-L73`:

- GET per il singolo budget e per la lista;
- POST su `budgets` per create;
- PATCH su `budget` per update;
- il serializer `BUDGET_SERIALIZER` e il normalizer `BUDGET_NORMALIZER` per le conversioni.

La `SearchConfig`, compresa l'eventuale `query` della ricerca, finisce nei `queryParams` di `buildUrl` — `feature-libs/organization/administration/occ/adapters/occ-budget.adapter.ts:L81-L86`. Il normalizer converte `startDate`/`endDate` da datetime a date. Il serializer fa l'inverso e porta `endDate` a fine giornata — `feature-libs/organization/administration/occ/converters/occ-budget-normalizer.ts:L20-L26`, `feature-libs/organization/administration/occ/converters/occ-budget-serializer.ts:L22-L28`. `OccCostCenterAdapter.loadList` usa `costCentersAll`, mentre `create` usa `costCenters`. `assignBudget` fa POST con `budgetCode` come query param e body `null` — `feature-libs/organization/administration/occ/adapters/occ-cost-center.adapter.ts:L41-L92`.

Il core di Spartacus ha già i converter OCC dei cost center in `CostCenterOccModule`, che aggiunge anche l'endpoint `getActiveCostCenters`. `AdministrationOccModule` lo importa — `core-libs/core/src/occ/adapters/cost-center/cost-center-occ.module.ts:L20-L40`, `core-libs/core/src/occ/adapters/cost-center/default-occ-cost-centers-config.ts:L9-L18`.

3.12 Le altre entità: dove divergono dal budget

- **Unità (albero).** `UnitListService` costruisce la lista da `OrgUnitService.getTree()`, inizializza `UnitTreeService` con la key corrente e appiattisce l'albero nei nodi espansi. La ricerca è client-side su `id`/`name` (toggle `enableB2BUnitSearch`) — `feature-libs/organization/administration/components/unit/services/unit-list.service.ts:L50-L95`. `filterTree` tiene il nodo che corrisponde con tutti i figli. Per gli antenati di un match tiene solo i rami corrispondenti e li forza espansi — `feature-libs/organization/administration/components/unit/services/unit-list.service.ts:L97-L142`. I nodi ricevono `count`, `expanded`, `depthLevel` e `uid = id` (commento "tmp, should be normalized") — `feature-libs/organization/administration/components/unit/services/unit-list.service.ts:L155-L189`. L'espansione combina il toggle globale, quello del singolo nodo e `minimalExpanded = 1` — `feature-libs/organization/administration/components/unit/services/unit-tree.service.ts:L26-L91`.
- **Utenti.** La key è `customerId`. I ruoli vengono filtrati su quelli noti e la ricerca dipende da `enableB2BCustomerSearch` — `feature-libs/organization/administration/components/user/services/user-list.service.ts:L52-L95`. I ruoli disponibili sono una lista fissa di quattro, "not driven by the backend (lack of API)" — `feature-libs/organization/administration/core/services/b2b-user.service.ts:L349-L364`. Alla creazione di un utente il customerId non è noto. L'effect naviga quindi direttamente a `orgUserDetails` (workaround dichiarato), tranne quando il contesto di route è `/organization/units`. Emette poi due `CreateB2BUserSuccess`, uno con i dati reali e uno con l'id temporaneo — `feature-libs/organization/administration/core/store/effects/b2b-user.effect.ts:L85-L113`, `feature-libs/organization/administration/core/store/effects/b2b-user.effect.ts:L641-L648`. Creando un utente da un'unità, `UnitUserItemService.create` imposta `customerId = 'new'` come id temporaneo da tracciare —

feature-libs/organization/administration/components/unit/links/users/create/unit-user-item.service.ts:L49-L60.

- **Cost center.** La ricerca dipende da `enableB2BCostCenterSearch` — feature-libs/organization/administration/components/cost-center/services/cost-center-list.service.ts:L55-L57. L'assegnazione dei budget osserva lo stato di loading del **budget**, perché le azioni `AssignBudget` marcano l'entità `BUDGET_ENTITIES` — feature-libs/organization/administration/components/cost-center/budgets/cost-center-budget-list.service.ts:L46-L64, feature-libs/organization/administration/core/store/actions/cost-center.action.ts:L242-L254.

I tre toggle di ricerca sono `true` nei `defaultFeatureToggles` — core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L252-L265, core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1044-L1046.

3.13 Account summary

`AccountSummaryRootModule` registra quattro cose — feature-libs/organization/account-summary/root/account-summary-root.module.ts:L37-L59:

- una route `path: null` (con `@ts-ignore`) per `cxRoute: 'orgAccountSummaryDetails'`, protetta da `CmsPageGuard`;
- la routing config;
- i CMS component lazy;
- un `BlobErrorInterceptor` in `HTTP_INTERCEPTORS`.

Le route sono `organization/account-summary` e `organization/account-summary/details/:orgUnit` — feature-libs/organization/account-summary/root/config/default-account-summary-routing.config.ts:L9-L23. `AccountSummaryFacade` è una facade lazy con `getAccountSummary`, `getDocumentList` e `getDocumentAttachment` — feature-libs/organization/account-summary/root/facade/account-summary.facade.ts:L17-L30. `AccountSummaryService` memorizza `userId` e `orgUnitId` in campi aggiornati da sottoscrizioni nel costruttore, e restituisce le chiamate al connector con `shareReplay(1)` — feature-libs/organization/account-summary/core/facade/account-summary.service.ts:L27-L82.

La lista **riusa il framework administration**. `AccountSummaryModule` importa `AdministrationModule` — feature-libs/organization/account-summary/account-summary.module.ts:L13-L21. La CMS config sostituisce `ListService`/`ItemService` con le versioni account summary e dichiara la child route `:unitCode` — feature-libs/organization/account-summary/components/list/account-summary-list.config.ts:L47-L84. `OrganizationTableType` viene esteso a runtime con `ACCOUNT_SUMMARY_UNIT` — feature-libs/organization/account-summary/components/model/augmented.model.ts:L10-L16. `AccountSummaryUnitListService` estende `UnitListService` cambiando solo `tableType` — feature-libs/organization/account-summary/components/services/account-summary-unit-list.service.ts:L15-L17.

Il download degli allegati usa `responseType: 'blob'`. Per questo `BlobErrorInterceptor` riconverte in JSON i corpi d'errore `Blob` (solo nel browser) — feature-libs/organization/account-summary/occ/adapters/occ-account-summary.adapter.ts:L71-L90, feature-libs/organization/account-summary/root/http-interceptors/blob-error.interceptor.ts:L31-L55. Il componente scarica con `URL.createObjectURL` + `FileDownloadService.download` — feature-libs/organization/account-summary/components/details/document/account-summary-document.component.ts:L133-L142.

3.14 Order approval, unit order, user registration

Order approval. Il root dichiara 7 CMS component lazy con dipendenza `ORDER_FEATURE`, una route `path: null` per `orderApprovalDetails` con `AuthGuard, CmsPageGuard`, e le route `my-account/approval-dashboard` e `my-`

account/approval/:approvalCode — feature-libs/organization/order-approval/root/order-approval-root.module.ts:L21-L72. Non ci sono entry point /core e /occ: il public API principale esporta tutto — feature-libs/organization/order-approval/public_api.ts:L7-L16. OrderApprovalService non ha una facade astratta. Usa lo store NgRx e il process state orderApproval.makeDecision — feature-libs/organization/order-approval/core/services/order-approval.service.ts:L116-L143, feature-libs/organization/order-approval/core/store/order-approval-state.ts:L10-L14. L'effect makeDecision$ ignora gli utenti anonimi e, su successo, ricarica l'approvazione — feature-libs/organization/order-approval/core/store/effects/order-approval.effect.ts:L97-L114. Il dettaglio riusa i componenti di @spartacus/order sostituendo OrderDetailsService con OrderApprovalDetailService — feature-libs/organization/order-approval/components/details/order-approval-details.module.ts:L45-L94. Il servizio legge approvalCode dallo stato del router e chiama loadOrderApproval a ogni emissione — feature-libs/organization/order-approval/components/details/order-approval-detail.service.ts:L19-L32. ApproverGuard ammette approver e admin — feature-libs/organization/order-approval/core/guards/approver.guard.ts:L29-L52.

Unit order. Il root dichiara 4 CMS component lazy e due route path: null. Quella di dettaglio ha un cxContext ORDER_ENTRIES_CONTEXT — feature-libs/organization/unit-order/root/unit-order-root.module.ts:L23-L82. UnitOrderFacade usa facadeFactory con async: true — feature-libs/organization/unit-order/root/facade/unit-order.facade.ts:L13-L33. Con async il resolver aggiunge un delay(0), "required to make lazy NgRx store feature ready" — core-libs/core/src/lazy-loading/facade-factory/facade-descriptor.ts:L32-L36, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L38-L57. Lo stato è la feature NgRx 'unit order' (con uno spazio nel nome) — feature-libs/organization/unit-order/core/store/unit-order-state.ts:L10-L21. UnitLevelOrdersViewerGuard ammette unitorderviewergroup o b2badmingroup — feature-libs/organization/unit-order/core/guards/unit-level-orders-viewer.guard.ts:L30-L54.

User registration. Il root dichiara solo 3 CMS component lazy, senza routing config — feature-libs/organization/user-registration/root/user-registration-root.module.ts:L11-L34. UserRegistrationService implementa la facade con un Command — feature-libs/organization/user-registration/core/facade/user-registration.service.ts:L16-L41. L'adapter fa POST su /orgUsers con l'header USE_CLIENT_TOKEN — feature-libs/organization/user-registration/occ/adapters/occ-user-registration.adapter.ts:L37-L57. Per il client token vedi il cap. 22. I dati aziendali non vengono inviati come campi strutturati: finiscono nel message tramite la chiave i18n userRegistrationForm.messageToApproverTemplate — feature-libs/organization/user-registration/components/form/user-registration-form.service.ts:L144-L200. Dopo l'invio si reindirizza al login solo con ResourceOwnerPasswordFlow o con il toggle authorizationCodeFlowByDefault — feature-libs/organization/user-registration/components/form/user-registration-form.service.ts:L177-L206. I componenti sono protetti da NotAuthGuard — feature-libs/organization/user-registration/components/verification-token-form/verification-token-form.module.ts:L51-L70. Un HttpErrorHandler dedicato gestisce i 409 — feature-libs/organization/user-registration/core/user-registration-core.module.ts:L14-L28.

3.15 Stili, schematic e test

feature-libs/organization/_index.scss definisce il mixin visible-focus e importa gli stili di administration, order-approval, user-registration, account-summary e unit-order (feature-libs/organization/_index.scss:L3-L15). Lo schematic addSpartacusOrganization segue la sequenza standard analyzeApplication → addFeatures → addPackageJsonDependenciesForLibrary → finalizeInstallation (feature-libs/organization/schematics/add-organization/index.ts:L25-L45); lo spec ha un blocco per ciascuna delle cinque feature (feature-libs/organization/schematics/add-organization/index_spec.ts:L126-L459) e per administration verifica con snapshot anche il modulo di configurazione B2B generato (feature-libs/organization/schematics/add-organization/index_spec.ts:L162-L170). feature-libs/organization/vitest.config.ts mappa numerosi path core-libs/... di helper di test (pagination, split view, url pipe, mock transla-

tion) sui sorgenti (feature-libs/organization/vitest.config.ts:L16-L34) e limita il pool a maxWorkers: 4 (feature-libs/organization/vitest.config.ts:L37-L37).

---

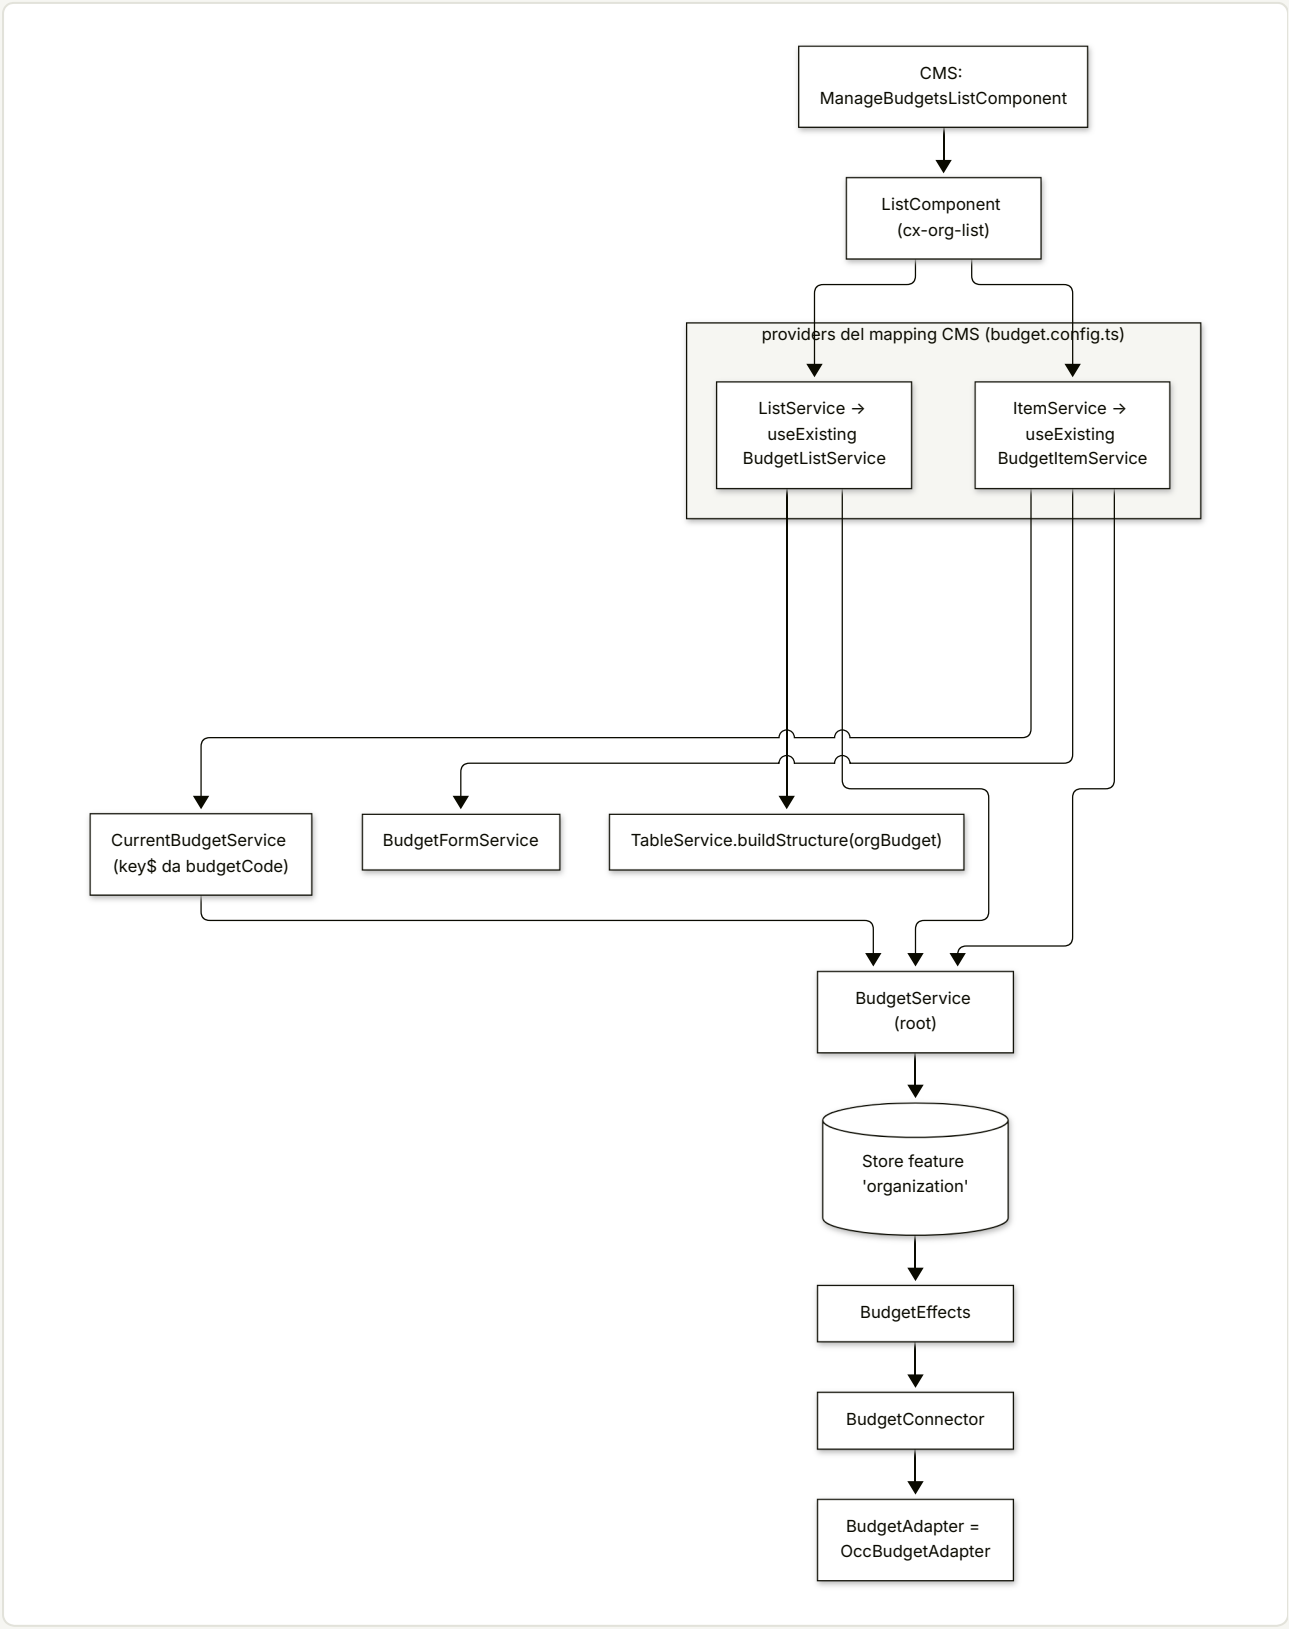
4. Diagrammi

4.1 Prima apertura di /organization/budgets: lazy loading, guardie, child route

■ TAVOLA 28.1 diagramma a tutta pagina, in fondo al capitolo

Riferimenti: sez. 3.4 (core-libs/storefront/cms-structure/guards/cms-page.guard.ts:L51-L70, core-libs/storefront/cms-structure/guards/cms-page-guard.service.ts:L65-L99, core-libs/storefront/cms-structure/services/cms-guards.service.ts:L36-L48, core-libs/storefront/cms-structure/services/cms-routes-impl.service.ts:L69-L124) e sez. 3.5.

4.2 Composizione DI: un `ListComponent`, sei entità



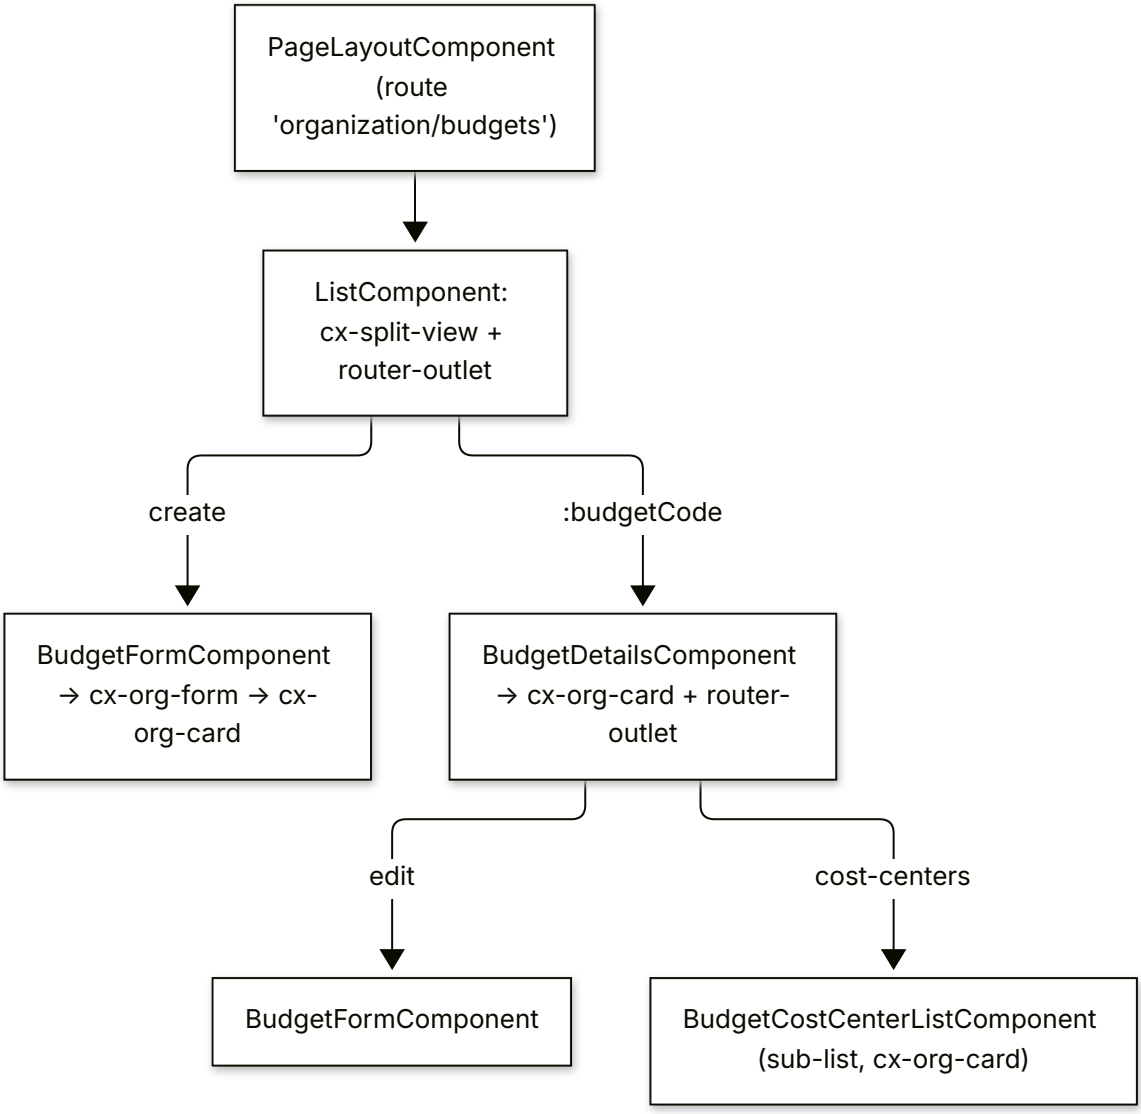
Riferimenti: `feature-libs/organization/administration/components/budget/budget.config.ts:L29-L42`, `feature-libs/organization/administration/components/budget/services/budget-item.service.ts:L22-L30`, `feature-libs/organization/administration/components/budget/services/budget-list.service.ts:L30-L38`, `feature-libs/organization/administration/occ/administration-occ.module.ts:L58-L80`.

4.3 Salvataggio del form budget (create)

■ TAVOLA 28.2 diagramma a tutta pagina, in fondo al capitolo

Riferimenti: sez. 3.7, 3.8, 3.10 (feature-libs/organization/administration/components/shared/item.service.ts:L47-L65, feature-libs/organization/administration/core/store/effects/budget.effect.ts:L86-L112, feature-libs/organization/administration/core/utils/get-item-status.ts:L15-L31). Nel ramo `EMPTY` la sottoscrizione di `FormComponent.save` non riceve mai un valore, quindi `form.enable()` non viene chiamato. Non serve, perché il form invalido non era stato disabilitato.

4.4 Split view: livelli di router-outlet



Riferimenti: feature-libs/organization/administration/components/budget/budget.config.ts:L52-L76, feature-libs/organization/administration/components/shared/list/list.component.html:L208-L211, feature-libs/organization/administration/components/shared/card/card.component.html:L36-L63.

5. Estratti di codice reale

5.1 Il mapping CMS del budget

feature-libs/organization/administration/components/budget/budget.config.ts:L29-L81

```ts
export const budgetCmsConfig: CmsConfig = {
  cmsComponents: {
    ManageBudgetsListComponent: {
      component: ListComponent,
      providers: [
        {
          provide: ListService,
          useExisting: BudgetListService,
        },
        {
          provide: ItemService,
          useExisting: BudgetItemService,
        },
      ],
      childRoutes: {
        parent: {
          data: {
            cxPageMeta: {
              breadcrumb: 'orgBudget.breadcrumbs.list',
              resolver: BudgetRoutePageMetaResolver,
            },
          },
        },
        children: [
          {
            path: 'create',
            component: BudgetFormComponent,
          },
          {
            path: `:${ROUTE_PARAMS.budgetCode}`,
            component: BudgetDetailsComponent,
            // ...
            children: [
              {
                path: `edit`,
                component: BudgetFormComponent,
              },
              {
                path: 'cost-centers',
                component: BudgetCostCenterListComponent,
              },
            ],
```

```
          },
        ],
      },
      guards: [AuthGuard, AdminGuard],
    },
  },
};
```

5.2 Child route aggiunte a runtime

core-libs/storefront/cms-structure/services/cms-routes-impl.service.ts:L93-L124

```ts
  private updateRouting(
    pageContext: PageContext,
    pageLabel: string,
    childRoutesConfig: CmsComponentChildRoutesConfig
  ): boolean {
    if (
      pageContext.type === PageType.CONTENT_PAGE &&
      pageLabel.startsWith('/') &&
      pageLabel.length > 1
    ) {
      const children = this.wrapCmsGuardsRecursively(
        childRoutesConfig.children ?? []
      );

      const newRoute: CmsRoute = {
        path: pageLabel.substring(1),
        component: PageLayoutComponent,
        children: children,
        data: deepMerge({}, childRoutesConfig?.parent?.data ?? {}, {
          cxCmsRouteContext: {
            type: pageContext.type,
            id: pageLabel,
          },
        }),
      };

      this.router.resetConfig([newRoute, ...this.router.config]);
      return true;
    }

    return false;
  }
```

5.3 `CurrentItemService`: la chiave viene dalla route

feature-libs/organization/administration/components/shared/current-item.service.ts:L30-L42

```ts
readonly key$: Observable<string> = this.routingService.getParams().pipe(
  map((params) => params[this.getParamKey()]),
  distinctUntilChanged()
);

/**
 * Observes the active item.
 *
 * The active item is loaded by the active `key$`.
 */
readonly item$: Observable<T | undefined> = this.key$.pipe(
  switchMap((code: string) => (code ? this.getItem(code) : of(undefined)))
);
```

5.4 ItemService.save

feature-libs/organization/administration/components/shared/item.service.ts:L47-L65

```ts
save(
  form: UntypedFormGroup,
  key?: string
): Observable<OrganizationItemStatus<T>> {
  if (form.invalid) {
    form.markAllAsTouched();
    FormUtils.deepUpdateValueAndValidity(form);
    return EMPTY;
  } else {
    /**
     * This assignment is needed to re-use form value after `form.disable()` call
     * In some cases value was converted by `form.disable()` into empty object
     */
    const formValue = form.value;
    form.disable();

    return key ? this.update(key, formValue) : this.create(formValue);
  }
}
```

5.5 FormComponent.save

feature-libs/organization/administration/components/shared/form/form.component.ts:L90-L112

```ts
save(form: UntypedFormGroup): void {
  this.itemService.key$
    .pipe(
      first(),
      switchMap((key) =>
```

```
        this.itemService.save(form, key).pipe(
          take(1),
          map((data) => ({
            item: data.item,
            status: data.status,
            action: key ? 'update' : 'create',
          }))
        )
      )
    )
    .subscribe(({ item, action, status }) => {
      if (status === LoadStatus.SUCCESS) {
        this.itemService.launchDetails(item);
        this.notify(item, action);
      }
      form.enable();
    });
}
```

5.6 `ListService.getData`: ghost data prima di ogni load

feature-libs/organization/administration/components/shared/list/list.service.ts:L117-L129

TS

```
getData(...args: any): Observable<EntitiesModel<T> | undefined> {
  return this.pagination$.pipe(
    // we merge any configured pagination from the table structure
    switchMap((pagination) =>
      this.getStructure().pipe(
        map((config) => ({ ...pagination, ...config.options?.pagination }))
      )
    ),
    switchMap((pagination) =>
      this.load(pagination, ...args).pipe(startWith(this.ghostData))
    )
  );
}
```

5.7 `BudgetService.get` e `getList`: load implicito

feature-libs/organization/administration/core/services/budget.service.ts:L75-L104

TS

```
get(budgetCode: string): Observable<Budget> {
  const loading$ = this.getBudgetState(budgetCode).pipe(
    auditTime(0),
    tap((state) => {
      if (!(state.loading || state.success || state.error)) {
        this.loadBudget(budgetCode);
```

```
        }
      })
    );

    return using(
      () => loading$.subscribe(),
      () => this.getBudgetValue(budgetCode)
    );
  }

  getList(params: SearchConfig): Observable<EntitiesModel<Budget> | undefined> {
    return this.getBudgetList(params).pipe(
      observeOn(queueScheduler),
      tap((process: StateUtils.LoaderState<EntitiesModel<Budget>>) => {
        if (!(process.loading || process.success || process.error)) {
          this.loadBudgets(params);
        }
      }),
      filter((process: StateUtils.LoaderState<EntitiesModel<Budget>>) =>
        Boolean(process.success || process.error)
      ),
      map((result) => result.value)
    );
  }
```

5.8 getItemStatus

feature-libs/organization/administration/core/utils/get-item-status.ts:L15-L31

TS

```
export function getItemStatus<T>(
  itemState: Observable<StateUtils.LoaderState<T>>
): Observable<OrganizationItemStatus<T>> {
  return itemState.pipe(
    observeOn(queueScheduler),
    pairwise(),
    filter(([previousState]) => previousState.loading ?? false),
    map(([_previousState, currentState]) => ({
      status: currentState.success
        ? LoadStatus.SUCCESS
        : currentState.error
          ? LoadStatus.ERROR
          : null,
      item: currentState.value,
    }))
  );
}
```

5.9 Create effect e meta-reducer

feature-libs/organization/administration/core/store/effects/budget.effect.ts:L94-L109

```ts
      switchMap((payload) =>
        this.budgetConnector.create(payload.userId, payload.budget).pipe(
          switchMap((data) => [
            new BudgetActions.CreateBudgetSuccess(data),
            new OrganizationActions.OrganizationClearData(),
          ]),
          catchError((error: HttpErrorResponse) =>
            from([
              new BudgetActions.CreateBudgetFail({
                budgetCode: payload.budget.code ?? '',
                error: tryNormalizeHttpError(error, this.logger),
              }),
              new OrganizationActions.OrganizationClearData(),
            ])
          )
        )
```

feature-libs/organization/administration/core/store/reducers/index.ts:L209-L227

```ts
export function clearOrganizationState(
  reducer: ActionReducer<OrganizationState, Action>
): ActionReducer<OrganizationState, Action> {
  return function (state, action) {
    if (action.type === OrganizationActions.CLEAR_ORGANIZATION_DATA) {
      state = undefined;
    }
    if (action.type === AuthActions.LOGOUT) {
      state = undefined;
    }
    if (action.type === SiteContextActions.LANGUAGE_CHANGE) {
      state = undefined;
    }

    return reducer(state, action);
  };
}

export const metaReducers: MetaReducer<any>[] = [clearOrganizationState];
```

5.10 Guardie nel child injector

feature-libs/organization/administration/core/guards/organization-guards.module.ts:L12-L21

```ts
@NgModule({
  // To ensure effective over-providing from within the child injector of a lazy-loaded module
  // by other extension libraries or end-user customizations, it's essential to provide guards manually
  // in the child injector and not in the root injector (providedIn: 'root').
  //
  // If guards were provided in the root injector, the only place to over-provide them or their dependencies
  // would be the root injector (root module), which would break lazy loading for those guards and their dependencies.
  providers: [AdminGuard, UserGuard, OrgUnitGuard],
})
export class OrganizationsGuardsModule {}
```

5.11 Toggle status: conferma solo in disattivazione, patch minimo

feature-libs/organization/administration/components/shared/detail/toggle-status-action/toggle-status.component.ts:L118-L138

```ts
  protected update(item: T): void {
    this.itemService
      .update(
        item[this.key as keyof BaseItem] as string,
        this.getPatchedItem(item)
      )
      .pipe(
        take(1),
        filter((data) => data.status === LoadStatus.SUCCESS)
      )
      .subscribe((data) => this.notify({ ...item, ...data.item }));
  }

  protected getPatchedItem(item: T): T {
    const patch: BaseItem = {};

    Object.assign(patch, { [this.key]: item[this.key as keyof T] });

    patch.active = !item.active;
    return patch as T;
  }
```

5.12 Estendere un enum a runtime (account summary)

feature-libs/organization/account-summary/components/model/augmented.model.ts:L10-L16

```ts
declare module '@spartacus/organization/administration/components' {
  enum OrganizationTableType {
    ACCOUNT_SUMMARY_UNIT = 'orgAccountSummary',
```

```
  }
}

(OrganizationTableType as any)['ACCOUNT_SUMMARY_UNIT'] = 'orgAccountSummary';
```

6. Configurazione

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
`organizationUI.listSearch.minCharacters`	number	3	`feature-libs/organization/administration/root/config/default-organization-ui.config.ts:L9-L15` (tipo `feature-libs/organization/administration/root/config/organization-ui.config.ts:L17-L30`)	`feature-libs/organization/administration/components/shared/list/list.service.ts:L221-L223`

Tutti i valori di `OrganizationTableType`, che fanno da root i18n di liste e card, compaiono come namespace del chunk `organization`. Il chunk ne contiene anche altri (`organization`, `orgUnitAssignedRoles`, `orgUnitUserRoles`, `orgUnitAssignedUsers`) — `feature-libs/organization/administration/assets/translations/translations.ts:L9-L41`, `feature-libs/organization/administration/components/shared/organization.model.ts:L9-L50`. Per il caricamento dei chunk vedi il cap. 37.

---

7. Commenti e note notevoli dal sorgente

- "Provides CRUD operations for all organization entities. This base class simplifies the various entity implementation, and ensures a consistent component implementation." — `feature-libs/organization/administration/components/shared/item.service.ts:L17-L22`. È la dichiarazione d'intenti dell'intero framework.
- "This assignment is needed to re-use form value after `form.disable()` call..." — `feature-libs/organization/administration/components/shared/item.service.ts:L56-L59`. Spiega perché l'ordine "leggi valore, poi disabilita" non va invertito.
- "while we should be able to reset with initial value, this doesn't always work hence, we're patching afterwards." — `feature-libs/organization/administration/components/shared/form/form.service.ts:L30-L31`.
- "TODO: rename to `viewType`" — `feature-libs/organization/administration/components/shared/list/list.service.ts:L66-L66`. Nelle sottoclassi la proprietà resta `tableType`.
- "// TODO: abstract" su `assign` — `feature-libs/organization/administration/components/shared/sub-list/sub-list.service.ts:L34-L34`.
- "As we can't filter with the backend API, we do this client side." — `feature-libs/organization/administration/components/shared/sub-list/sub-list.service.ts:L46-L48`.
- "// TODO: this doesn't work with lazy loaded feature" sulla routing config dei gruppi utenti — `feature-libs/organization/administration/root/config/default-user-group-routing.config.ts:L15-L15`.
- "// TODO: Inline this factory when we start releasing Ivy compiled libraries" — `feature-libs/organization/administration/root/administration-root.module.ts:L24-L24`. Lo stesso commento compare nei root module di account-summary, order-approval e unit-order (non in user-registration) — `feature-libs/organization/account-summary/root/account-summary-root.module.ts:L20-L20`, `feature-libs/organization/order-approval/root/order-approval-root.module.ts:L20-L20`, `feature-libs/organization/unit-order/root/unit-order-root.module.ts:L22-L22`, `feature-libs/organization/user-registration/root/user-registration-root.module.ts:L10-L11`.
- "routing as temporary solution until /organization won't have set up proper permission on backend" — `feature-libs/organization/administration/core/guards/admin.guard.ts:L36-L37`.

- Il commento che motiva la registrazione delle guardie nel child injector — feature-libs/organization/administration/core/guards/organization-guards.module.ts:L13-L18.
- "// TODO: for future releases, refactor this part to thrown errors" (gli errori di takeUserId vengono ignorati) — feature-libs/organization/administration/core/services/budget.service.ts:L42-L42.
- "// TODO Workaround for not known customerId while user creation (redireciton)" — feature-libs/organization/administration/core/store/effects/b2b-user.effect.ts:L87-L87.
- "Note: No id or code is provided when creating a new user so we cannot store a value in the ngrx state..." — feature-libs/organization/administration/components/unit/links/users/create/unit-user-item.service.ts:L52-L56.
- @deprecated Use budgetTableConfig instead. su newBudgetTableConfig — feature-libs/organization/administration/components/budget/budget.config.ts:L129-L132.
- "This is not for the public API" / "TODO:#my-account-architecture - Number.MAX_VALUE?" su MAX_OCC_INTEGER_VALUE = 2147483647 — feature-libs/organization/administration/components/constants.ts:L7-L9.
- "The views are router based, which means if we close a view, the router outlet is cleaned immediately..." — feature-libs/organization/administration/components/shared/card/card.component.ts:L68-L72.
- "We use a child view container ref, as creating components will become siblings." — feature-libs/organization/administration/components/shared/message/message.component.ts:L30-L31.
- "// we don't want to run this logic when doing SSR" — feature-libs/organization/administration/components/shared/message/base-message.component.ts:L70-L70.
- Il blocco AUGMENTABLE_TYPES_START … AUGMENTABLE_TYPES_END attorno all'export di OrganizationTableType — feature-libs/organization/administration/components/public_api.ts:L16-L18.
- Il JSDoc Returns 'budgetDetails' contraddice il codice, che ritorna 'orgBudgetDetails' — feature-libs/organization/administration/components/budget/services/budget-item.service.ts:L56-L62.
- "When enabled, the organization's table component will stop re-rendering its rows each data update..." (toggle a11yCardNotificationMessage) — core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L238-L242.

8. Extension point

EXTENSION POINT	COME SI USA	DEFINIZIONE	RICETTA
ItemService<T>, CurrentItemService<T>	sottoclasse e sostituzione nei providers del mapping CMS (o nei providers del componente form)	feature-libs/organization/administration/components/shared/item.service.ts:L23-L132, feature-libs/organization/administration/components/shared/current-item.service.ts:L18-L70	Ricette CMS, outlet e layout
ListService<T,P>, SubListService<T>	sottoclasse (tableType, load, key, isSearchEnabled, getCreateButtonType, assign/unassign)	feature-libs/organization/administration/components/shared/list/list.service.ts:L20-L243, feature-libs/organization/administration/components/shared/sub-list/sub-list.service.ts:L18-L64	Ricette CMS, outlet e layout

EXTENSION POINT	COME SI USA	DEFINIZIONE	RICETTA
`FormService<T>`	sottoclasse (`build`, `defaultValue`)	`feature-libs/organization/administration/components/shared/form/form.service.ts:L11-L58`	Ricette CMS, outlet e layout
`CmsConfig.cmsComponents.Manage*ListComponent`	`provideConfig` con `component`, `providers`, `childRoutes`, `guards` sostitutivi	`feature-libs/organization/administration/components/budget/budget.config.ts:L29-L81`	Ricette CMS, outlet e layout
`TableConfig` per `OrganizationTableType`	`provideConfig({ table: { orgBudget: … } })` (celle, `dataComponent`, paginazione)	`feature-libs/organization/administration/components/budget/budget.config.ts:L87-L127`	Ricette CMS, outlet e layout
`CellComponent` e celle derivate	componente custom referenziato da `dataComponent`	`feature-libs/organization/administration/components/shared/table/cell.component.ts:L31-L111`	Ricette CMS, outlet e layout
`MessageService` / `MessageData.component`	messaggio custom che estende `BaseMessageComponent`	`feature-libs/organization/administration/components/shared/message/services/message.service.ts:L14-L56`, `feature-libs/organization/administration/components/shared/message/message.model.ts:L42-L47`	Ricette CMS, outlet e layout
`OrganizationTableType`	module augmentation + assegnazione runtime (vedi 5.12)	`feature-libs/organization/administration/components/shared/organization.model.ts:L9-L35`, `feature-libs/organization/administration/components/public_api.ts:L16-L18`	Upgrade-safe
Routing config delle entità, `ROUTE_PARAMS`	`provideConfig({ routing: { routes: { orgBudget: { paths: [...] } } } })`	`feature-libs/organization/administration/root/config/default-budget-routing.config.ts:L10-L38`, `feature-libs/organization/administration/root/route-params.ts:L10-L18`	Ricette config e DI
`OrganizationUIConfig`	`provideConfig({ organizationUI: { listSearch: { minCharacters } } })`	`feature-libs/organization/administration/root/config/organization-ui.config.ts:L13-L34`	Ricette config e DI
`AdminGuard`, `OrgUnitGuard`, `UserGuard`	override nel child injector del feature lazy (es. modulo importato nel wrapper accanto ad `AdministrationModule`)	`feature-libs/organization/administration/core/guards/organization-guards.module.ts:L12-L21`	Ricette config e DI
`OrgUnitService.isUpdatingUnitAllowed`, `B2BUserService.isUpdatingUserAllowed`	override del servizio per abilitare i guard	`feature-libs/organization/administration/core/services/org-unit.service.ts:L501-L503`, `feature-libs/organization/administration/core/services/b2b-user.service.ts:L414-L416`	Ricette config e DI

EXTENSION POINT	COME SI USA	DEFINIZIONE	RICETTA
`OrganizationConflictHandler`, `OrganizationBadRequestHandler`	nuovo `HttpErrorHandler` multi o sottoclasse con regex aggiuntive	feature-libs/organization/administration/core/http-interceptors/conflict/conflict.handler.ts:L20-L92	Ricette config e DI
`BudgetAdapter` & co., token `BUDGET_NORMALIZER/BUDGET_SERIALIZER`, `COST_CENTER_NORMALIZER`	adapter custom (`useClass`) o converter aggiuntivi (`multi`)	feature-libs/organization/administration/core/connectors/budget/budget.adapter.ts:L11-L34, feature-libs/organization/administration/core/connectors/budget/converters.ts:L11-L20, core-libs/core/src/cost-center/connectors/cost-center/converters.ts:L12-L22	Ricette OCC e dati
Endpoint OCC (`backend.occ.endpoints.*`)	`provideConfig` con endpoint sostitutivi	feature-libs/organization/administration/occ/config/default-occ-organization-config.ts:L9-L75	Ricette OCC e dati
`OrganizationPageMetaResolver`	sottoclasse con `getScore` più alto (come fa `AccountSummaryPageMetaResolver`)	feature-libs/organization/administration/core/services/organization-page-meta.resolver.ts:L38-L131, feature-libs/organization/account-summary/core/account-summary-page-meta.resolver.ts:L31-L103	Ricette OCC e dati
`AccountSummaryFacade`, `UnitOrderFacade`, `UserRegistrationFacade`	facade lazy: override del servizio di implementazione nel feature	feature-libs/organization/account-summary/root/facade/account-summary.facade.ts:L17-L30, feature-libs/organization/unit-order/root/facade/unit-order.facade.ts:L13-L33, feature-libs/organization/user-registration/root/facade/user-registration.facade.ts:L13-L31	Ricette feature lazy
`OrderApprovalDetailService`	servizio sostitutivo di `OrderDetailsService` nei componenti order	feature-libs/organization/order-approval/components/details/order-approval-detail.service.ts:L15-L66	Ricette CMS, outlet e layout
Feature module lazy (wrapper)	aggiungere estensioni accanto ad `AdministrationModule`, come fa la demo con CDC	projects/storefrontapp/src/app/spartacus/features/organization/administration-wrapper.module.ts:L12-L20	Ricette feature lazy

Due note pratiche.

Override dei guard. Non serve ridichiarare il mapping CMS. Basta fornire la propria classe con `{ provide: AdminGuard, useClass: … }` in un modulo caricato **dentro** il feature lazy. Il guard viene istanziato tramite `UnifiedInjector` — core-libs/storefront/cms-structure/services/cms-guards.service.ts:L41-L45 — e il commento in feature-libs/organization/administration/core/guards/organization-guards.module.ts:L13-L18 spiega che un override nel root injector romperebbe il lazy loading.

Nuova entità o vista. Il percorso più breve è quello dell'account summary:

- estendere `OrganizationTableType`;
- sottoclassare un `ListService` esistente cambiando `tableType`;
- dichiarare un CMS mapping con il componente lista adatto e i propri provider `ListService`/`ItemService`. L'account summary usa `AccountSummaryListComponent extends UnitListComponent`; per una lista piatta si usa `ListComponent` — feature-libs/organization/account-summary/components/list/account-summary-list.config.ts:L49-L51, feature-libs/organization/account-summary/components/list/account-summary-list.component.ts:L18-L18.

Riferimenti: feature-libs/organization/account-summary/components/services/account-summary-unit-list.service.ts:L15-L17, feature-libs/organization/account-summary/components/list/account-summary-list.config.ts:L47-L84.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. `LoadStatus.SUCCESS` **vale** `0`**, cioè falsy.** `if (data.status)` non funziona. Il codice confronta sempre con `=== LoadStatus.SUCCESS` — feature-libs/organization/administration/core/model/organization-item-status.ts:L7-L10, feature-libs/organization/administration/components/shared/form/form.component.ts:L106-L106.
2. **Ogni create/update di budget azzera tutto lo stato** `organization`. Succede anche quando l'operazione fallisce, perché viene emesso `OrganizationClearData`. Liste, alberi e relazioni vengono ricaricati da zero — feature-libs/organization/administration/core/store/effects/budget.effect.ts:L96-L107, feature-libs/organization/administration/core/store/reducers/index.ts:L209-L227. Lo stesso reset avviene al cambio lingua — feature-libs/organization/administration/core/store/reducers/index.ts:L219-L221.
3. `getItemStatus` **vede solo la transizione.** Se ci si sottoscrive dopo che il loading è già finito, non arriva alcun esito. L'id osservato deve inoltre coincidere con l'id marcato dall'azione — feature-libs/organization/administration/core/utils/get-item-status.ts:L19-L21.
4. **Update con codice cambiato.** `BudgetItemService.update(code, value)` osserva `getLoadingStatus(value.code)`, e `UpdateBudget` marca `budget.code`. Se il codice nel form diverge dalla key di route, il loading viene tracciato sul nuovo codice — feature-libs/organization/administration/components/budget/services/budget-item.service.ts:L43-L49, feature-libs/organization/administration/core/store/actions/budget.action.ts:L132-L140.
5. **Create utente.** `UserItemService.create` osserva `getLoadingStatus(value.uid ?? '')`, ma il form utente non ha un controllo `uid` (ha `customerId`, vuoto in creazione), quindi l'id osservato è `''` — feature-libs/organization/administration/components/user/services/user-item.service.ts:L45-L50, feature-libs/organization/administration/components/user/form/user-form.service.ts:L22-L24. `CreateB2BUser` marca come loading `customerId ?? null`, e `entityReducer` converte un id `null` in `''` — feature-libs/organization/administration/core/store/actions/b2b-user.action.ts:L128-L134, core-libs/core/src/state/utils/entity/entity.reducer.ts:L28-L33. Entrambi gli id collassano quindi sull'entità `''`. Il secondo `CreateB2BUserSuccess`, quello con il `customerId` temporaneo, chiude la transizione, e `FormComponent` riceve `SUCCESS` — feature-libs/organization/administration/core/store/effects/b2b-user.effect.ts:L92-L97. La navigazione principale al dettaglio la fa comunque l'effect (`redirectToDetails`) — feature-libs/organization/administration/core/store/effects/b2b-user.effect.ts:L88-L90. Lo skip del redirect dipende dalla stringa hardcoded `'/organization/units'` — feature-libs/organization/administration/core/store/effects/b2b-user.effect.ts:L641-L648.

6. **Un solo form per entità.** Il `FormService` sono `providedIn: 'root'`, quindi lo stato del form sopravvive alle navigazioni e viene resettato o patchato a ogni `getForm` — feature-libs/organization/administration/components/shared/form/form.service.ts:L20-L37, feature-libs/organization/administration/components/budget/form/budget-form.service.ts:L18-L21. `BudgetFormComponent` chiama `getForm()` senza item in un field initializer, `FormComponent.form$` lo richiama con l'item: le due chiamate condividono lo stesso `FormGroup` — feature-libs/organization/administration/components/budget/form/budget-form.component.ts:L67-L67, feature-libs/organization/administration/components/shared/form/form.component.ts:L65-L75.
7. **Entità disattivata = form disabilitato.** `patchData` disabilita il form se `active === false` — feature-libs/organization/administration/components/shared/form/form.service.ts:L39-L51. Visto che il form è unico (punto 6), aprire un'entità disattivata e poi una attiva riabilita il form solo perché `active === true` scatena il ramo `enable`.
8. `orgUnits` **vs** `orgUnit`**.** La route lista delle unità è `orgUnits`, ma `OrganizationTableType.UNIT` vale `'orgUnit'`. I link "create" (`structure.type + 'Create'` → `orgUnitCreate`) e le celle (`_type + 'Details'` → `orgUnitDetails`) funzionano perché producono nomi che esistono. Una route costruita come `type` senza suffisso non esisterebbe — feature-libs/organization/administration/root/config/default-units-routing.config.ts:L20-L29, feature-libs/organization/administration/components/shared/organization.model.ts:L15-L15, feature-libs/organization/administration/components/shared/list/list.component.html:L135-L135.
9. **Le child route esistono solo dopo la prima visita.** Vengono create da `handleCmsRoutesInGuard` solo per content page con label che inizia con `/` — core-libs/storefront/cms-structure/services/cms-routes-impl.service.ts:L98-L102. Il primo ingresso costa una navigazione annullata e una ripetuta (`navigateByUrl` + `return false`) — core-libs/storefront/cms-structure/services/cms-routes-impl.service.ts:L83-L88.
10. `AdminGuard` **può restare sospeso.** Filtra finché l'utente non è caricato (`Object.keys(user).length > 0`). Se `UserAccountFacade.get()` non emette mai un utente non vuoto, la navigazione non si risolve — feature-libs/organization/administration/core/guards/admin.guard.ts:L28-L29.
11. `OrgUnitGuard` **e** `UserGuard` **sono no-op** finché qualcuno non sovrascrive `isUpdating*Allowed` — feature-libs/organization/administration/core/services/org-unit.service.ts:L501-L503, feature-libs/organization/administration/core/services/b2b-user.service.ts:L414-L416.
12. **La sotto-lista "cost center del budget" filtra per** `active`, non per `selected` come il `filterSelected` di base. Mostra solo i cost center attivi annidati nel budget — feature-libs/organization/administration/components/budget/cost-centers/budget-cost-center-list.service.ts:L46-L56, feature-libs/organization/administration/components/shared/sub-list/sub-list.service.ts:L49-L63. La table config imposta `pageSize: MAX_OCC_INTEGER_VALUE` (2147483647), ma `load` ignora la paginazione: i cost center vengono dai dati annidati del budget (`getCostCenters`), senza una chiamata dedicata — feature-libs/organization/administration/components/budget/budget.config.ts:L121-L123, feature-libs/organization/administration/components/budget/cost-centers/budget-cost-center-list.service.ts:L33-L40.
13. `cachedValues` **si aggiorna anche con lista vuota.** La condizione `length >= 0` è sempre vera — feature-libs/organization/administration/components/shared/list/list.component.ts:L178-L181.
14. **Il** `MessageService` **della card è condiviso.** Sta nei `providers`, quindi i componenti proiettati (toggle-status, delete-item) e `cxOrgItemActive` sull'host usano la stessa istanza — feature-libs/organization/administration/components/shared/card/card.component.ts:L34-L34, angular:adev/src/content/guide/di/debugging-and-troubleshooting-di.md:L279-L287. Spostarlo in `viewProviders` in una sottoclasse romperebbe i messaggi delle azioni proiettate.
15. `@ViewChild(MessageService)` **in** `SubListComponent` **è lecito.** Sembra strano, ma `@ViewChild` accetta un provider definito nell'albero dei componenti figli. Qui trova quello della `cx-org-card` nel template — feature-

libs/organization/administration/components/shared/sub-list/sub-list.component.ts:L46-L47, angular:packages/core/src/metadata/di.ts:L431-L436.

16. **Testi e nomi da sapere.** "assign"/"unassign" sono hardcoded nel template della cella e non tradotti — feature-libs/organization/administration/components/shared/sub-list/assign-cell.component.ts:L28-L32. La table config dei permessi si chiama `permisionTableConfig` (con il refuso) — feature-libs/organization/administration/components/permission/permission.config.ts:L79-L79. `CostCenterService.get` è tipato `Observable<Budget>` — feature-libs/organization/administration/core/services/cost-center.service.ts:L87-L101.
17. **API Angular deprecate.** `MessageRenderService` usa `ComponentFactoryResolver`/`ComponentFactory` — feature-libs/organization/administration/components/shared/message/services/message-render.service.ts:L7-L26.
18. **Endpoint senza slash iniziale.** `accountSummary*` e `unitLevelOrderDetail` non hanno lo slash iniziale, gli altri sì — feature-libs/organization/account-summary/occ/config/default-occ-account-summary-config.ts:L10-L15, feature-libs/organization/unit-order/occ/config/default-occ-organization-config.ts:L13-L14. È innocuo: `urlPathJoin` rimuove gli slash ai bordi di ogni parte e conserva solo quello iniziale della prima, il base URL — core-libs/core/src/occ/utils/occ-url-util.ts:L12-L33, core-libs/core/src/occ/services/occ-endpoints.service.ts:L233-L238.
19. **Campi asincroni in** `AccountSummaryService`**.** `userId` e `orgUnitId` vengono letti da campi impostati in modo asincrono nel costruttore. Se un metodo viene chiamato prima delle emissioni, i valori sono `undefined`. `getAccountSummary` usa `??`, gli altri due metodi usano `||` — feature-libs/organization/account-summary/core/facade/account-summary.service.ts:L32-L73. Il download crea un object URL senza `revokeObjectURL` nel codice letto — feature-libs/organization/account-summary/components/details/document/account-summary-document.component.ts:L133-L142. Il resolver usa l'etichetta hardcoded `'Account Summaries'` — feature-libs/organization/account-summary/core/account-summary-page-meta.resolver.ts:L42-L42.
20. **Load ripetuti nell'order approval.** `approvalCode$` deriva da `getRouterState()` senza `distinctUntilChanged`, quindi ogni emissione dello stato del router con un codice valorizzato rilancia `loadOrderApproval`, anche se il codice non cambia. Il fallback di `get()` (load se lo stato è vuoto) di solito non scatta, perché il dispatch del `tap` avviene prima della sottoscrizione a `get()` — feature-libs/organization/order-approval/components/details/order-approval-detail.service.ts:L19-L30, feature-libs/organization/order-approval/core/services/order-approval.service.ts:L74-L85.
21. `CostCenterModule.forRoot()` **di core è vuoto** e non risulta importato nelle librerie — core-libs/core/src/cost-center/cost-center.module.ts:L9-L17. I converter OCC dei cost center sono altrove, in `CostCenterOccModule` — core-libs/core/src/occ/adapters/cost-center/cost-center-occ.module.ts:L20-L40.

---

10. Come fare debug

- **"La lista non compare / redirect a organization".** Verifica i ruoli dell'utente: `AdminGuard` richiede `b2badmingroup` e reindirizza con il warning `organization.notification.noSufficientPermissions` — feature-libs/organization/administration/core/guards/admin.guard.ts:L31-L46. Se la pagina resta bianca senza redirect, controlla che `UserAccountFacade.get()` emetta un utente non vuoto (trappola 10).
- **Child route non attive (404 su** `/organization/budgets/xyz`**).** Ispeziona `router.config` dopo la prima visita: deve comparire una route `organization/budgets` con `data.cxCmsRouteContext` — core-libs/storefront/cms-structure/services/cms-routes-impl.service.ts:L107-L119. Se manca, la pagina CMS non è una

content page con label `/organization/budgets`, oppure il mapping del componente non ha `childRoutes` (sez. 3.4).

- **Store.** In Redux DevTools apri lo slice `organization.budget`: ci sono `entities` (chiave `code`) e `list` (chiave = `serializeSearchConfig(params)`) — feature-libs/organization/administration/core/store/reducers/index.ts:L94-L105, feature-libs/organization/administration/core/store/actions/budget.action.ts:L64-L75. Dopo un salvataggio deve comparire l'azione `'[Organization] Clear Data'` (`CLEAR_ORGANIZATION_DATA`) e lo stato tornare vuoto — feature-libs/organization/administration/core/store/actions/organization.action.ts:L9-L9, feature-libs/organization/administration/core/store/reducers/index.ts:L213-L215.
- **Il form non naviga dopo Save.** Controlla in DevTools che l'entità con id = `value.code` passi da `loading: true` a `success: true`. `getItemStatus` reagisce solo a quella transizione — feature-libs/organization/administration/core/utils/get-item-status.ts:L19-L28. Se l'azione marcasse un id diverso da quello osservato, non arriverebbe alcun `SUCCESS`.
- **Il form resta disabilitato.** `save()` disabilita il form prima della chiamata — feature-libs/organization/administration/components/shared/item.service.ts:L60-L61. `FormComponent` lo riabilita solo quando arriva un esito — feature-libs/organization/administration/components/shared/form/form.component.ts:L105-L110. Se `getItemStatus` non emette mai, il form resta disabilitato. Un'altra causa è un item con `active === false` (trappola 7).
- **Errore 409/400 senza messaggio specifico.** Gli handler intervengono solo se il messaggio corrisponde alle loro regex — feature-libs/organization/administration/core/http-interceptors/conflict/conflict.handler.ts:L29-L31. Altrimenti decide la catena generica (cap. 41).
- **Tabella "random" o colonne sbagliate.** `TableService.buildStructure` ricade sulla struttura random quando manca una `table.<viewType>` — core-libs/storefront/shared/components/table/table.service.ts:L49-L58. Verifica che `tableType` del tuo `ListService` coincida con la chiave della table config.
- **Breakpoint utili:**
  - `ListService.getData` (feature-libs/organization/administration/components/shared/list/list.service.ts:L117-L129);
  - `ItemService.save` (feature-libs/organization/administration/components/shared/item.service.ts:L47-L65);
  - `CmsRoutesImplService.handleCmsRoutesInGuard` (core-libs/storefront/cms-structure/services/cms-routes-impl.service.ts:L69-L91);
  - `CmsGuardsService.cmsPageCanActivate` (core-libs/storefront/cms-structure/services/cms-guards.service.ts:L36-L48).
- **Rete.** Una lista budget produce un GET su `/users/{userId}/budgets` con `pageSize`, `currentPage`, `sort` ed eventuale `query` come query string — feature-libs/organization/administration/occ/adapters/occ-budget.adapter.ts:L81-L86. Le date in uscita sono datetime con `endDate` a fine giornata — feature-libs/organization/administration/occ/converters/occ-budget-serializer.ts:L22-L28.

---

11. Domande di autoverifica

1. **Perché esiste un solo `ListComponent` per sei entità, e come sa quali dati caricare?** Il mapping CMS di ogni `Manage*ListComponent` fornisce `ListService` e `ItemService` con `useExisting` verso le implementazioni dell'entità. Il componente inietta le astrazioni — feature-libs/organization/administration/components/budget/budget.config.ts:L31-L42, feature-libs/organization/administration/components/shared/list/list.component.ts:L109-L114.

2. **In che ordine il guard CMS carica il feature, esegue** `AdminGuard` **e crea le child route?** Prima `determineMappings` (lazy loading), poi `cmsPageCanActivate` (guardie). Solo se l'esito è `true` e manca `cxCmsRouteContext` viene chiamato `handleCmsRoutesInGuard` — core-libs/storefront/cms-structure/guards/cms-page-guard.service.ts:L65-L99.
3. **Perché** `AdminGuard` **non è** `providedIn: 'root'`**, e come viene trovato?** È fornito nel child injector del modulo lazy per permetterne l'override senza rompere il lazy loading — feature-libs/organization/administration/core/guards/organization-guards.module.ts:L13-L19. Viene risolto tramite `UnifiedInjector` — core-libs/storefront/cms-structure/services/cms-guards.service.ts:L41-L45.
4. **Da dove viene la "chiave" dell'item corrente in un pannello di dettaglio?** Dai parametri di route, con la chiave restituita da `getParamKey()` (es. `budgetCode`) — feature-libs/organization/administration/components/shared/current-item.service.ts:L30-L33, feature-libs/organization/administration/components/budget/services/current-budget.service.ts:L32-L33.
5. **Come fa la UI a sapere che un create è riuscito, se** `BudgetService.create` **ritorna** `void`**?** `getLoadingStatus` usa `getItemStatus`, che con `pairwise()` intercetta la transizione da `loading` a `success`/`error` dell'entità — feature-libs/organization/administration/core/services/budget.service.ts:L145-L149, feature-libs/organization/administration/core/utils/get-item-status.ts:L15-L31.
6. **Perché** `if (status)` **sarebbe un bug?** `LoadStatus.SUCCESS` vale `0` — feature-libs/organization/administration/core/model/organization-item-status.ts:L7-L10.
7. **Cosa succede allo stato NgRx dopo un update di budget, anche fallito?** L'effect emette `OrganizationClearData`, e il meta-reducer imposta `state = undefined` per tutta la feature `organization` — feature-libs/organization/administration/core/store/effects/budget.effect.ts:L122-L139, feature-libs/organization/administration/core/store/reducers/index.ts:L209-L227.
8. **Perché** `ItemService.save` **legge** `form.value` **prima di** `form.disable()`**?** Perché in alcuni casi `disable()` trasforma il valore in un oggetto vuoto (commento nel sorgente) — feature-libs/organization/administration/components/shared/item.service.ts:L56-L61.
9. **Come si aggiunge una vista basata sul framework in un'altra libreria senza toccare l'enum originale?** Con module augmentation di `OrganizationTableType` più un'assegnazione runtime, poi una sottoclasse di `ListService` con il nuovo `tableType`, come fa l'account summary — feature-libs/organization/account-summary/components/model/augmented.model.ts:L10-L16, feature-libs/organization/account-summary/components/services/account-summary-unit-list.service.ts:L15-L17.
10. **Perché** `UnitOrderFacade` **usa** `async: true`**?** Il resolver aggiunge un `delay(0)` dopo aver risolto il feature, per dare tempo alla feature NgRx lazy di essere pronta — core-libs/core/src/lazy-loading/facade-factory/facade-descriptor.ts:L32-L36, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L53-L55, feature-libs/organization/unit-order/root/facade/unit-order.facade.ts:L13-L33.
11. **Perché un componente proiettato in** `cx-org-card` **vede il** `MessageService` **della card?** `CardComponent` lo dichiara nei `providers`, che in Angular sono visibili anche al contenuto proiettato (a differenza dei `viewProviders`) — feature-libs/organization/administration/components/shared/card/card.component.ts:L34-L34, angular:adev/src/content/guide/di/debugging-and-troubleshooting-di.md:L285-L287.

TAVOLA 28.1 **4.1 Prima apertura di /organization/budgets: lazy loading, guardie, child route**

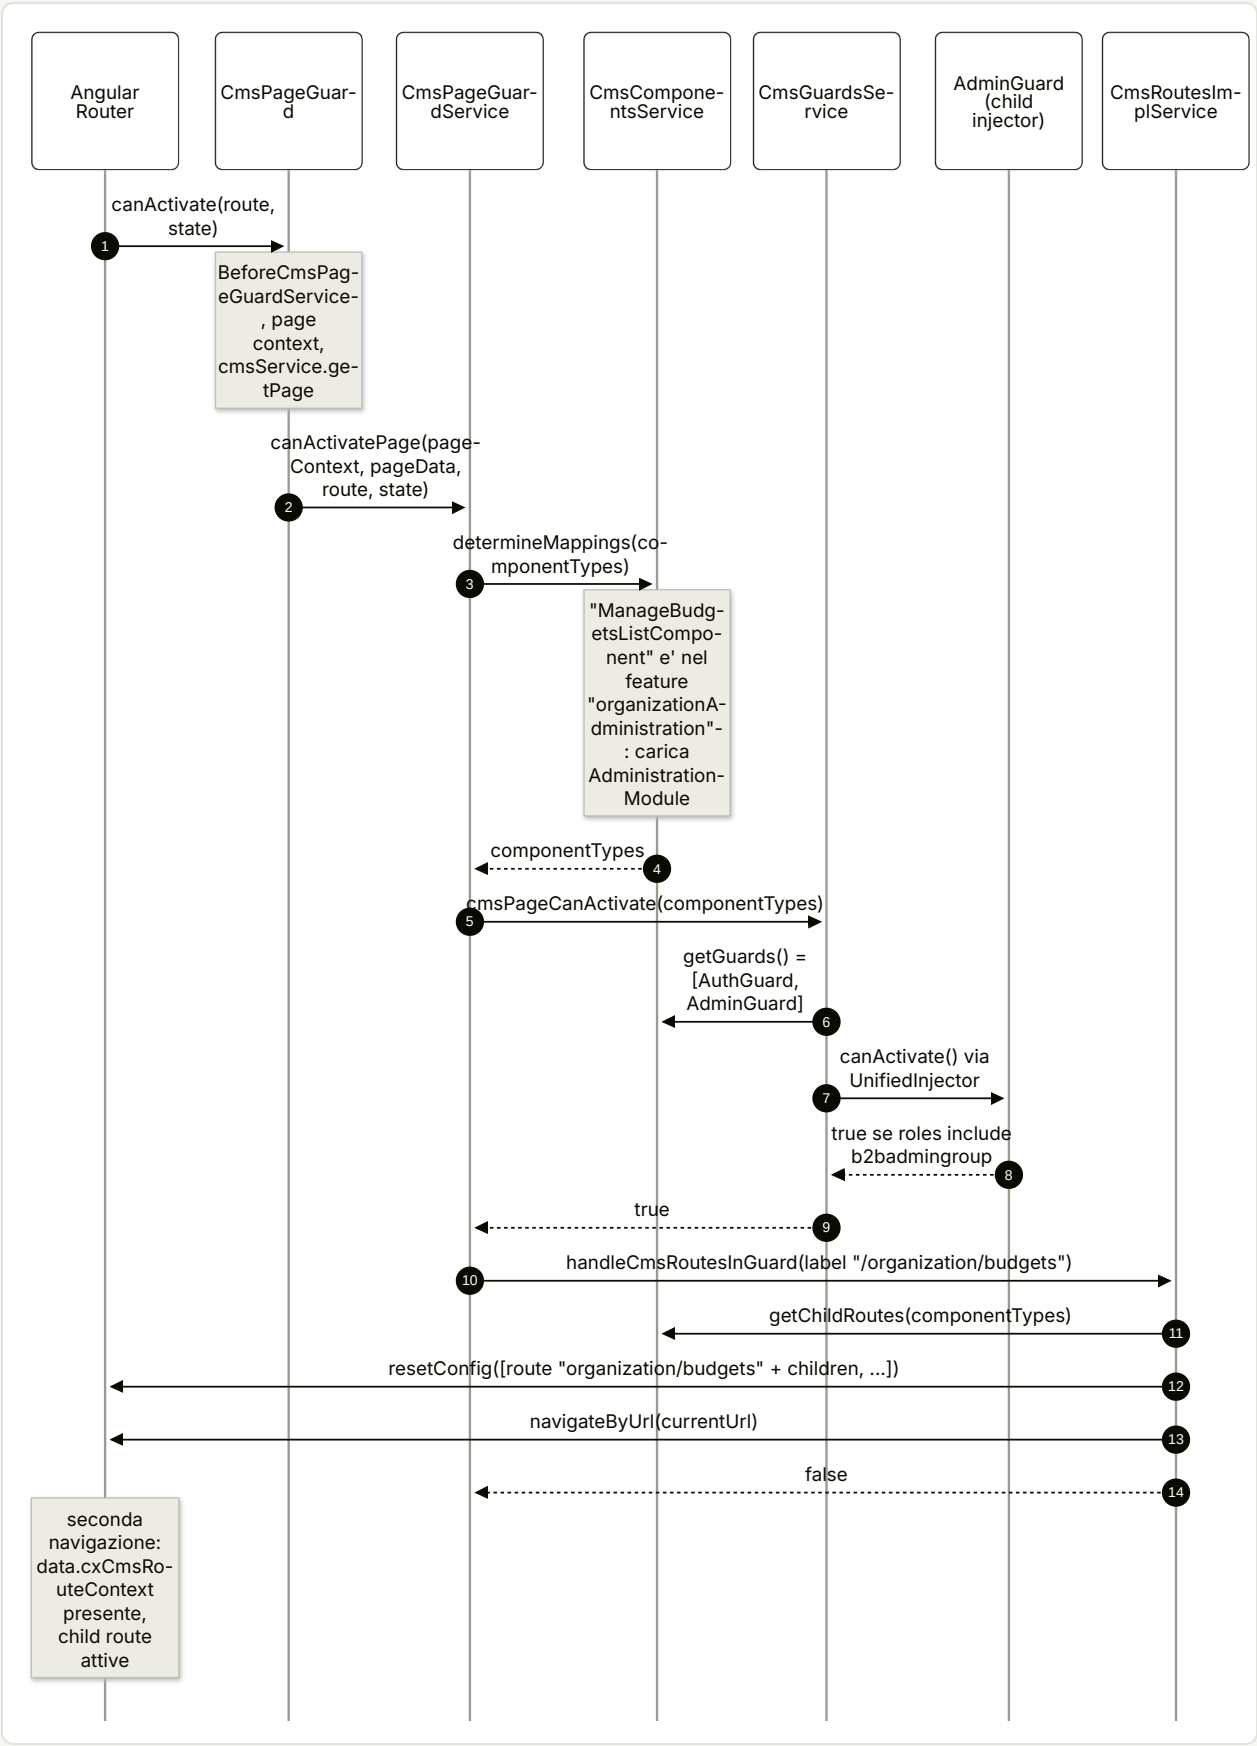

TAVOLA 28.2 **4.3 Salvataggio del form budget (create)**

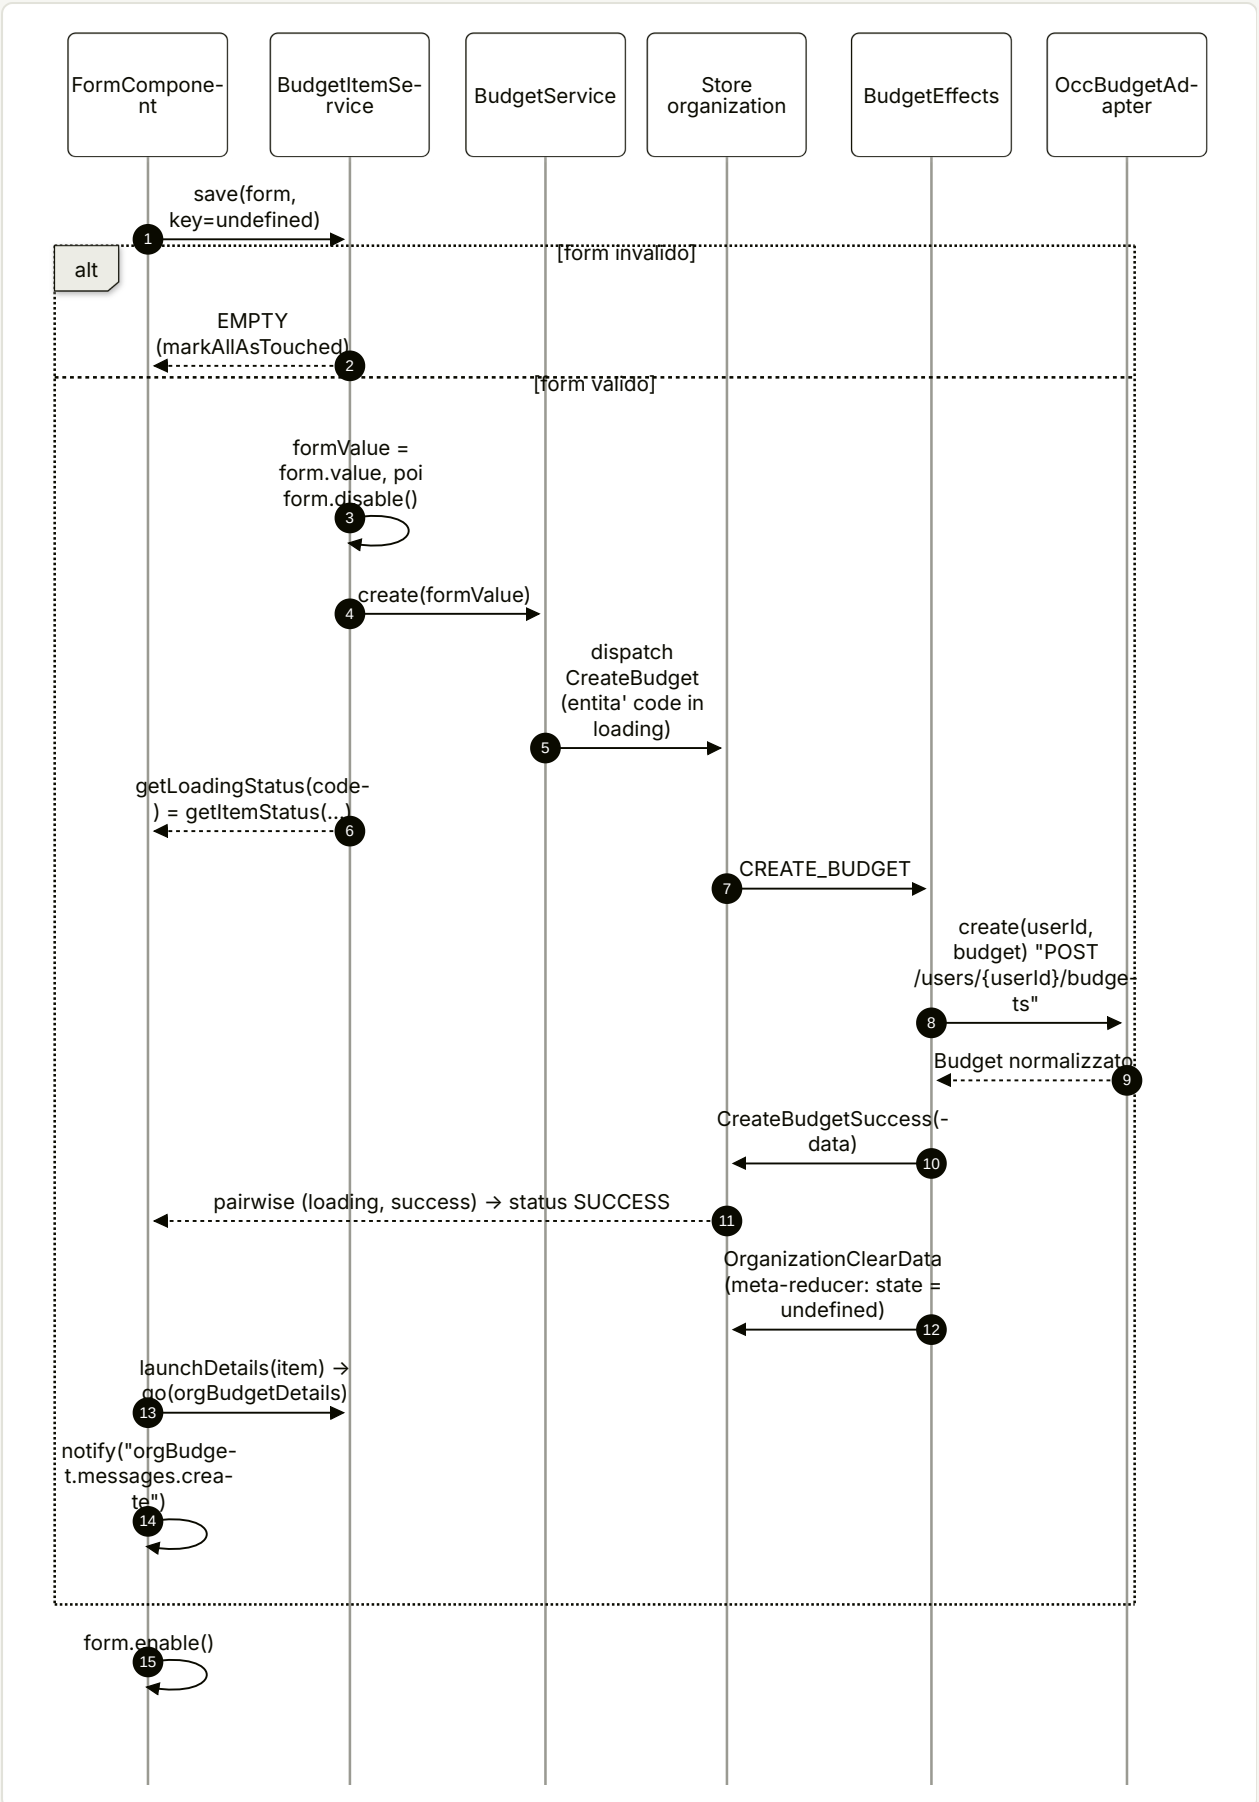

29

ASM (Assisted Service Module)

Il customer support agent che emula un cliente: ricerca, sessione, carrello, Customer 360.

IN QUESTO CAPITOLO

1. A cosa serve e perché esiste
2. Mappa dei file
3. Come funziona passo per passo

11. Domande di autoverifica

Riferimenti allo SHA `5b7a1c2bf2808d7380bc20596d10f4fa710c3da1` (vedi 00-meta).

1. A cosa serve e perché esiste

L'Assisted Service Module (`@spartacus/asm`) permette a un **customer support agent** (CS agent: commesso in negozio o operatore di call center) di autenticarsi nello storefront con le proprie credenziali e di **emulare** un cliente: cercarlo, aprire una sessione "come se fosse lui", vederne e modificarne il carrello, legare un carrello anonimo al suo account, crearne l'account, consultare una vista aggregata (Customer 360). Tutto questo avviene nello stesso storefront usato dai clienti, sopra una barra ASM che si apre solo quando serve.

Dal punto di vista architetturale ASM è interessante per tre ragioni:

1. **È una feature lazy che però deve modificare il cuore dell'autenticazione.** La parte eager (`AsmRootModule`) sostituisce con `useExisting` quattro servizi del core — `AuthStorageService`, `AuthService`, `AuthHttpHeaderService`, `ProtectedRoutesService` — e aggiunge un interceptor HTTP (`feature-libs/asm/root/asm-root.module.ts:L65-L92`). Il resto (store NgRx, componenti, adapter OCC) è caricato on demand con il nome feature `'asm'` (`feature-libs/asm/root/feature-name.ts:L7-L7`, `projects/storefrontapp/src/app/spartacus/features/asm/asm-feature.module.ts:L18-L27`).
2. **Due "identità" condividono un unico slot token.** Il core ha un solo token OAuth in `AuthStorageService`; ASM aggiunge un `TokenTarget` (`CSAgent` / `User`) che dice di chi è quel token, più un secondo token "emulato" del cliente da ripristinare (`feature-libs/asm/root/services/asm-auth-storage.service.ts:L18-L21`, `feature-libs/asm/root/services/asm-auth-storage.service.ts:L37-L50`). L'emulazione OCC, invece, è ottenuta impostando lo `userId` al `customerId` del cliente invece di `current` (`feature-libs/asm/root/services/csagent-auth.service.ts:L134-L141`).
3. **Non deve pesare sull'utente normale.** Lo dice esplicitamente il sorgente: "This service is added to avoid any polution of the UI and runtime performance for the ordinary production user" (`feature-libs/asm/root/services/asm-enabler.service.ts:L13-L17`). La UI viene caricata solo se l'URL contiene `asm=true`, se ASM è stato usato prima nel browser o se si arriva da un deep link di emulazione (`feature-libs/asm/root/services/asm-enabler.service.ts:L42-L49`).

Questo capitolo presuppone il capitolo 22 — Autenticazione (token, `AuthInterceptor`, `AuthHttpHeaderService`, `UserIdService`) e il capitolo 12 — Feature module e lazy loading (`featureModules`, `facadeFactory`). I dialog ASM usano il launch dialog descritto in 18 — Layout, breakpoint, launch dialog; lo store usa i loader di 19 — State management.

2. Mappa dei file

La libreria ha 12 entry point ng-packagr, uno per ogni `ng-package.json`: `feature-libs/asm/{,root,core,occ,components,assets}/ng-package.json` e `feature-libs/asm/customer-360/{,root,core,occ,components,assets}/ng-package.json`. L'entry point principale, per esempio, pubblica in `../../dist/asm` con `entryFile: ./public_api.ts` — `feature-libs/asm/ng-package.json:L1-L8`.

PATH	RUOLO
`feature-libs/asm/asm.module.ts`	`AsmModule = AsmComponentsModule + AsmCoreModule + AsmOccModule` (target del lazy load)

PATH	RUOLO
feature-libs/asm/root/asm-root.module.ts	eager: override servizi auth, route deep link `asmDeepLink`, interceptor, `defaultAsmConfig`
feature-libs/asm/root/asm-loader.module.ts	`APP_INITIALIZER` non bloccante → `AsmEnablerService.load()`
feature-libs/asm/root/asm-constants.ts	`ASM_ENABLED_LOCAL_STORAGE_KEY = 'asm_enabled'`
feature-libs/asm/root/feature-name.ts	`ASM_FEATURE = 'asm'`
feature-libs/asm/root/config/asm-config.ts	`AsmConfig` (abstract, `useExisting: Config`, augment di `Config`)
feature-libs/asm/root/config/default-asm-config.ts	`defaultAsmConfig` (timer, ricerca, customer list, header user id)
feature-libs/asm/root/services/asm-enabler.service.ts	decide se caricare la UI ASM
feature-libs/asm/root/services/asm-auth-storage.service.ts	`AsmAuthStorageService`, enum `TokenTarget`, token emulato
feature-libs/asm/root/services/csagent-auth.service.ts	`CsAgentAuthService`: login/logout agente, avvio emulazione
feature-libs/asm/root/services/asm-auth.service.ts	`AsmAuthService`: override di `AuthService`
feature-libs/asm/root/services/asm-auth-http-header.service.ts	`AsmAuthHttpHeaderService`: token agente sulle richieste marcate
feature-libs/asm/root/services/asm-protected-routes.service.ts	nessuna route protetta per l'agente loggato
feature-libs/asm/root/services/asm-deep-link.service.ts	parametri e navigazione del deep link
feature-libs/asm/root/interceptors/user-id-http-header.interceptor.ts	header `sap-commerce-cloud-user-id`
feature-libs/asm/root/facade/*.facade.ts	`AsmBindCartFacade`, `AsmCreateCustomerFacade`, `AsmCustomerListFacade` (proxy lazy)
feature-libs/asm/root/model/augmented-core.model.ts	augment di `LAUNCH_CALLER` con `ASM_*`
feature-libs/asm/core/asm-core.module.ts	store, connector, facade, `MODULE_INITIALIZER` di persistenza
feature-libs/asm/core/store/	stato `asm`: due loader di ricerca + `asmUi`; effects e meta-reducer
feature-libs/asm/core/facade/asm.service.ts	`AsmService` (dispatch/select sullo store)
feature-libs/asm/core/services/asm-state-persistence.service.ts	sync `{ui, emulatedUserToken, tokenTarget}` ↔ storage `asm`
feature-libs/asm/core/connectors/	`AsmAdapter`, `AsmConnector`, token normalizer

feature-libs/asm/styles/components/_asm-session-timer.component.scss	Placeholder `%cx-asm-session-timer`.
feature-libs/asm/styles/components/_asm-switch-customer-dialog.component.scss	Placeholder `%cx-asm-switch-customer-dialog`.
feature-libs/asm/styles/components/_asm-toggle-ui.component.scss	Placeholder `%cx-asm-toggle-ui`.
feature-libs/asm/styles/components/_csagent-login-form.component.scss	Placeholder `%cx-csagent-login-form`.

PATH	RUOLO
feature-libs/asm/styles/components/_customer-emulation.component.scss	Placeholder %cx-customer-emulation.
feature-libs/asm/styles/components/_customer-list.component.scss	Placeholder %cx-customer-list.
feature-libs/asm/styles/components/_customer-selection.component.scss	Placeholder %cx-customer-selection.
feature-libs/asm/styles/components/_dot-spinner.component.scss	Placeholder %cx-dot-spinner.

3. Come funziona passo per passo

3.1 Packaging: cosa è eager e cosa è lazy

L'app importa `AsmRootModule` eagerly e dichiara `featureModules[ASM_FEATURE].module: () => import('@spartacus/asm').then((m) => m.AsmModule)`; non sono dichiarati `cmsComponents`, perché la UI ASM non è un componente CMS (projects/storefrontapp/src/app/spartacus/features/asm/asm-feature.module.ts:L18-L27). `AsmModule` si limita a importare componenti, core e occ (feature-libs/asm/asm.module.ts:L12-L15).

`AsmRootModule` (feature-libs/asm/root/asm-root.module.ts:L34-L95) contiene tutto ciò che deve esistere **prima** che la feature sia caricata:

- importa `AsmLoaderModule` e `PageLayoutModule`;
- registra una route figlia con `path: null` (con `// @ts-ignore`), `CmsPageGuard`, `PageLayoutComponent` e `data.cxRoute: 'asmDeepLink'` nel contesto della home page CMS (feature-libs/asm/root/asm-root.module.ts:L38-L51); il path reale arriva dalla `RoutingConfig` di default `asmDeepLink.paths: ['assisted-service/emulate']` (feature-libs/asm/root/asm-root.module.ts:L56-L64) — vedi il meccanismo delle route semantiche nel capitolo 14 — Routing;
- fornisce `defaultAsmConfig` (feature-libs/asm/root/asm-root.module.ts:L55-L55);
- sostituisce i servizi auth del core e aggiunge `UserIdHttpHeaderInterceptor` (feature-libs/asm/root/asm-root.module.ts:L65-L92).

Il token `DELEGATED_AUTH_HTTP_HEADER_SERVICE` è fornito anch'esso con `AsmAuthHttpHeaderService`, come provider di retro-compatibilità per il fix CXSPA-12514 da rimuovere quando il toggle `enableExpiredRefreshTokenHandlers` sarà completamente attivo (feature-libs/asm/root/asm-root.module.ts:L77-L83). Il token vive nel core senza factory ed esiste perché altre librerie (es. Punchout) possano delegare all'override ASM senza importarlo a compile-time (core-libs/core/src/auth/user-auth/services/auth-http-header.service.ts:L72-L82).

3.2 Attivazione: `AsmLoaderModule` e `AsmEnablerService`

`AsmLoaderModule` registra un `APP_INITIALIZER` la cui factory ritorna una funzione `void`: chiama `AsmEnablerService.load()` senza restituire una Promise, quindi **non blocca il bootstrap** (feature-libs/asm/root/asm-loader.module.ts:L16-L40). Il commento motiva la scelta: router e state "aren't available in an optimized way during the APP_INITIALIZER" (feature-libs/asm/root/asm-loader.module.ts:L29-L34). Per l'ordine degli initializer vedi 10 — Bootstrap.

`AsmEnablerService.isEnabled()` (feature-libs/asm/root/services/asm-enabler.service.ts:L42-L49) restituisce vero se:

- `isLaunched()`: la query string di `Location.path()` contiene esattamente il parametro `asm=true` (feature-libs/asm/root/services/asm-enabler.service.ts:L55-L58);
- `isUsedBefore()`: `localStorage['asm_enabled'] === 'true'` (feature-libs/asm/root/services/asm-enabler.service.ts:L70-L79, costante in feature-libs/asm/root/asm-constants.ts:L7-L7);
- `isEmulateInURL()`: `location.path().indexOf('assisted-service/emulate?') > 0` (feature-libs/asm/root/services/asm-enabler.service.ts:L63-L65).

Al primo lancio via `asm=true` scrive `asm_enabled='true'`, così le visite successive riaprono la barra anche senza parametro (feature-libs/asm/root/services/asm-enabler.service.ts:L43-L47).

Se abilitato, `addUi()` risolve la feature `'asm'` (lazy load di `AsmModule`) e poi lancia `LAUNCH_CALLER.ASM` con il `LaunchDialogService` (feature-libs/asm/root/services/asm-enabler.service.ts:L84-L88). `LAUNCH_CALLER.ASM` è già nell'enum dello storefront (core-libs/storefront/layout/launch-dialog/config/launch-config.ts:L93-L94); la config di layout di default, fornita dai componenti, lo aggancia all'outlet `'cx-storefront'` con `AsmMainUiComponent` (feature-libs/asm/components/default-asm-layout.config.ts:L10-L17). `LaunchDialogService.launch()` trova la config del caller, sceglie la strategia di render e la invoca (core-libs/storefront/layout/launch-dialog/services/launch-dialog.service.ts:L78-L97); per una config con `outlet` è `OutletRenderStrategy`, che aggiunge il componente all'outlet in posizione `BEFORE` (default) e forza il render dell'outlet (core-libs/storefront/layout/launch-dialog/services/outlet-render.strategy.ts:L45-L84). Per gli outlet vedi 17 — Outlet.

Il lazy load di `AsmModule` porta con sé `AsmCoreModule`, che registra lo store (`AsmStoreModule`) e un `MODULE_INITIALIZER` che invoca `AsmStatePersistenceService.initSync()` (feature-libs/asm/core/asm-core.module.ts:L15-L35).

3.3 La duplicazione nel core: `AuthService.refreshAuthConfig()`

C'è un secondo punto che "sa" se ASM è attivo, e sta nel core. `AuthService` contiene una copia della logica di rilevamento (`isAsmEnabled`, `isLaunched`, `isEmulateInURL`, `isUsedBefore` con letterale `'asm_enabled'`) e la usa in `refreshAuthConfig()`: se il toggle `authorizationCodeFlowByDefault` è attivo e ASM è abilitato, il client OAuth diventa `'asm_client'` e `isUsingASMClient` passa a `true` (core-libs/core/src/auth/user-auth/facade/auth.service.ts:L263-L327). `refreshAuthConfig()` e `checkOAuthParamsInUrl()` sono invocati da un initializer del core, solo in browser e dopo che la config è stabile (core-libs/core/src/auth/user-auth/user-auth.module.ts:L43-L54). Con i default attuali `authorizationCodeFlowByDefault` vale `true` (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1029-L1029), quindi **il percorso normale del login agente è l'Authorization Code flow** (§3.6), non il form username/password.

3.4 `AsmConfig`

`AsmConfig` è una classe astratta `@Injectable({ providedIn: 'root', useExisting: Config })` con chiave `asm` e sotto-chiavi `agentSessionTimer`, `customerSearch`, `customerList`, `asmSessionSupport`, `userIdHttpHeader`, `createCustomer`; augmenta l'interfaccia `Config` di `@spartacus/core` (feature-libs/asm/root/config/asm-config.ts:L11-L59). I default sono in feature-libs/asm/root/config/default-asm-config.ts:L11-L84 (dettaglio nella §6). Siccome `defaultAsmConfig` è fornito dal modulo eager, è disponibile prima del lazy load (feature-libs/asm/root/asm-root.module.ts:L55-L55). Il meccanismo generale è nel capitolo 11 — Configurazione.

3.5 Il modello di stato dell'autenticazione ASM

`AsmAuthStorageService extends AuthStorageService` (feature-libs/asm/root/services/asm-auth-storage.service.ts:L37-L139) aggiunge due `BehaviorSubject`:

- `_tokenTarget$`, inizializzato a `TokenTarget.User`: dice se il token corrente è dell'agente o di un utente (feature-libs/asm/root/services/asm-auth-storage.service.ts:L38-L39);
- `emulatedUserToken$`: il token del cliente che era loggato quando l'agente ha fatto login "sopra" di lui (caso in-store), da ripristinare al logout dell'agente (feature-libs/asm/root/services/asm-auth-storage.service.ts:L41-L50).

Il costruttore legge **sincronicamente** lo stato persistito con chiave `'asm'` tramite `StatePersistenceService.readStateFromStorage` e ripristina token emulato e target (feature-libs/asm/root/services/asm-auth-storage.service.ts:L52-L69). Il motivo si deduce dal codice: la sincronizzazione completa (`initSync`) parte solo dopo il lazy load (§3.11), mentre il target del token serve già alle prime richieste intercettate (§3.8).

Combinando questi due valori con lo `userId` del core si ottengono i predicati chiave:

PREDICATO	DEFINIZIONE	RIFERIMENTO
agente loggato	token presente && target `CSAgent` && `access_token` ≠ quello del token emulato	feature-libs/asm/root/services/csagent-auth.service.ts:L148-L164
cliente emulato	`userId` ≠ `anonymous` e ≠ `current`	feature-libs/asm/root/services/csagent-auth.service.ts:L171-L173, core-libs/core/src/auth/user-auth/facade/user-id.service.ts:L81-L88
utente "loggato" (per il resto dello storefront)	token presente && (target `User` || (target `CSAgent` && emulato))	feature-libs/asm/root/services/asm-auth.service.ts:L201-L214

L'ultima riga è il trucco centrale: durante un'emulazione il token è dell'agente, ma per guard, carrello e checkout l'utente risulta loggato e le chiamate OCC usano `/users/<customerId>/...`.

3.6 Login dell'agente

Authorization Code flow (default). Con `authorizationCodeFlowByDefault` il template mostra il link "Sign In as Agent" invece del form (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.html:L45-L63, feature-libs/asm/components/asm-main-ui/asm-main-ui.component.html:L116-L124). Il click chiama `CsAgentAuthService.authorizeCustomerSupportAgentWhenUseCodeFlow()` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L386-L388), che:

1. legge sincronicamente `customerId` (da `UserAccountFacade.get()`) e il token utente corrente (feature-libs/asm/root/services/csagent-auth.service.ts:L90-L101);
2. **prima del redirect a pagina intera** persiste lo stato di emulazione: dispatch `Logout`; se c'era un cliente loggato `setUserId(customerId)` + `setEmulatedUserToken(userToken)` + `Login`, altrimenti `userId = anonymous` e token emulato pulito (feature-libs/asm/root/services/csagent-auth.service.ts:L103-L120). Il commento spiega che `initLoginFlow()` naviga via e ciò che segue "does not run reliably" (feature-libs/asm/root/services/csagent-auth.service.ts:L104-L106);
3. passa il target a `CSAgent` e chiama `initLoginFlow()`; in errore torna a `User` (feature-libs/asm/root/services/csagent-auth.service.ts:L122-L126).

Al ritorno dall'Authorization Server l'initializer del core chiama `refreshAuthConfig()` (che imposta di nuovo `asm_client`) e poi `checkOAuthParamsInUrl()`, che per DI è l'override di `AsmAuthService` (feature-libs/asm/root/services/asm-auth.service.ts:L69-L95): se non si usa il client ASM delega al core; altrimenti

`tryLogin()` e, se il token è stato ricevuto, target `CSAgent`, `userId = anonymous` **solo se non c'è già un'emulazione pendente** (CXSPA-13777), dispatch `Login` e `authRedirectService.redirect()`. Il core, simmetricamente, salta l'impostazione di `userId = current` quando `isEmulated` o `isUsingASMClient` è vero (core-libs/core/src/auth/user-auth/facade/auth.service.ts:L97-L104).

Password flow (toggle disattivato). `CSAgentLoginFormComponent` emette `{userId, password}` (feature-libs/asm/components/csagent-login-form/csagent-login-form.component.ts:L55-L64); `AsmMainUiComponent.loginCustomerSupportAgent()` chiama `authorizeCustomerSupportAgent()` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L376-L384), che passa il target a `CSAgent` **prima** di `authorizeWithPasswordFlow()`, poi dispatcha `Logout` e, come nel code flow, avvia subito l'emulazione del cliente già loggato oppure imposta `anonymous` (feature-libs/asm/root/services/csagent-auth.service.ts:L46-L84). Deduzione dal codice: il token restituito dal password flow finisce nello stesso `AuthStorageService` del token utente, quindi il target deve già dire "CSAgent" quando arriva.

3.7 Che cosa vede il resto dello storefront mentre l'agente è loggato

`AsmAuthService` ritocca il comportamento di `AuthService`:

- `loginWithCredentials()` rifiuta il login cliente (messaggio `asm.auth.agentLoggedInError`) se c'è un token con target `CSAgent` (feature-libs/asm/root/services/asm-auth.service.ts:L97-L134);
- `loginWithRedirect()`: se l'agente è attivo ma non emula nessuno, invece dell'errore reindirizza a `'/'`, per gestire guard come `CheckoutAuthGuard` che mandano a `/login` (feature-libs/asm/root/services/asm-auth.service.ts:L136-L156);
- `coreLogout()` in emulazione **non revoca** i token: pulisce il token emulato, `clearUserId()` e dispatcha `Logout`; altrimenti delega al core (feature-libs/asm/root/services/asm-auth.service.ts:L180-L196).

`AsmProtectedRoutesService.isUrlProtected()` restituisce `false` per qualsiasi URL quando l'agente è loggato, così può navigare le pagine CMS anche senza emulare (feature-libs/asm/root/services/asm-protected-routes.service.ts:L15-L43).

3.8 Le richieste HTTP: quale token, quali header

Le chiamate ai web service ASM sono marcate dall'adapter con l'header interceptor `cx-use-csagent-token` (`USE_CUSTOMER_SUPPORT_AGENT_TOKEN`, definito nel core: core-libs/core/src/occ/utils/interceptor-util.ts:L10-L10) e costruite con `{ baseSite: false, prefix: false }`, cioè fuori dal prefisso `/occ/v2/{site}` (feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L99-L121).

L'`AuthInterceptor` del core chiede a `AuthHttpHeaderService` se intercettare gli errori e se aggiungere l'header, prende il token stabile e chiama `alterRequest()` (core-libs/core/src/auth/user-auth/http-interceptors/auth.interceptor.ts:L31-L48). Per DI quel servizio è `AsmAuthHttpHeaderService`, che:

- estende `shouldAddAuthorizationHeader()` e `shouldCatchError()` alle richieste con `cx-use-csagent-token` (feature-libs/asm/root/services/asm-auth-http-header.service.ts:L60-L76);
- in `alterRequest()`, per le richieste CS agent senza `Authorization`, aggiunge l'header con il token e rimuove `cx-use-csagent-token` "to avoid problems with CORS" (feature-libs/asm/root/services/asm-auth-http-header.service.ts:L84-L106);
- per le richieste OCC **non** marcate, quando il target è `CSAgent` e c'è un token emulato con `access_token`, usa il token del cliente (`getTokenForRequest` / `shouldUseEmulatedUserToken`, feature-libs/asm/root/services/asm-auth-http-header.service.ts:L108-L133). È il caso in-store: l'agente ha fatto login sopra la sessione di un cliente, e le chiamate "normali" continuano col token di quest'ultimo;

- su refresh token scaduto, se l'agente è loggato imposta il logout in corso, esegue `logoutCustomerSupportAgent()` e mostra `asm.csagentTokenExpired`; altrimenti comportamento del core (feature-libs/asm/root/services/asm-auth-http-header.service.ts:L149-L167).

Altri due interceptor completano il quadro:

- `UserIdHttpHeaderInterceptor`: no-op se `asm.userIdHttpHeader.enable` è falsy; altrimenti legge `OCC_HTTP_TOKEN.sendUserIdAsHeader` dal context della richiesta: se stringa usa quel valore, se `true` usa `takeUserId()` scartando gli id costanti (`anonymous`, `current`, ...), e imposta l'header `sap-commerce-cloud-user-id` (feature-libs/asm/root/interceptors/user-id-http-header.interceptor.ts:L44-L84). Il context token è nel core (core-libs/core/src/occ/utils/occ-http-token.ts:L9-L20) e lo valorizzano, fra gli adapter core, product search e user cost centers (core-libs/core/src/occ/adapters/product/occ-product-search.adapter.ts:L52-L52, core-libs/core/src/occ/adapters/user/occ-user-cost-centers.adapter.ts:L33-L33). Il JSDoc della config avverte che l'header può rompere istanze Commerce che non lo consentono in CORS (feature-libs/asm/root/config/asm-config.ts:L39-L50);
- `SiteContextInterceptor` (registrato da `AsmCustomer360RootModule`, feature-libs/asm/customer-360/root/asm-customer-360-root.module.ts:L29-L33) aggiunge `lang` e `curr` come query param alle richieste verso il base URL OCC che contengono `/assistedservicewebservices/` (feature-libs/asm/customer-360/root/interceptors/site-context.interceptor.ts:L54-L72).

> DA VERIFICARE — L'ordine effettivo fra `UserIdHttpHeaderInterceptor`, `SiteContextInterceptor` e `AuthInterceptor` dipende dall'ordine con cui l'app importa i moduli che li registrano (multi provider `HTTP_INTERCEPTORS`); il codice ASM non lo fissa. Per il meccanismo generale vedi 06 — HttpClient e interceptor.

3.9 Ricerca cliente: store, effect, adapter

`CustomerSelectionComponent` cerca per nome (`searchTerm`) o per numero d'ordine (`searchOrder`) con `debounceTime(300)`, solo da 3 caratteri in su, con `pageSize = asm.customerSearch.maxResults`; i due campi si escludono (feature-libs/asm/components/customer-selection/customer-selection.component.ts:L96-L192). `AsmService` — servizio `providedIn: 'root'` che lavora sullo store, non una facade proxy — dispatcha `CustomerSearch` (feature-libs/asm/core/facade/asm.service.ts:L20-L79).

Lo stato `asm` (feature-libs/asm/core/store/asm-state.ts:L15-L23) contiene due `LoaderState<CustomerSearchPage>` (`customerSearchResult`, `customerListCustomersSearchResult`) e `asmUi`; `AsmStoreModule` registra la feature store con reducer, meta-reducer e gli effects `CustomerEffects` e `AsmSessionEffects` (feature-libs/asm/core/store/asm-store.module.ts:L16-L25). I reducer di ricerca sono `StateUtils.loaderReducer` (feature-libs/asm/core/store/reducers/index.ts:L24-L34).

`CustomerEffects.customerSearch$` usa `switchMap` (una nuova ricerca cancella la precedente) sul connector; un 400 con messaggio `'Wrong orderId'` è convertito in un successo vuoto, gli altri errori in `CustomerSearchFail` con l'errore normalizzato (feature-libs/asm/core/store/effects/customer.effect.ts:L18-L43). `OccAsmAdapter.customerSearch()` è una POST con body `{query, orderId, customerListId}` e query param `baseSite`, `sort` (default `byNameAsc` solo se non c'è `customerListId`), `pageSize`, `page` (feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L131-L186).

3.10 Avvio e fine dell'emulazione

Il submit della selezione emette `{ customerId, parameters: { orderId } }` (feature-libs/asm/components/customer-selection/customer-selection.component.ts:L221-L232). `AsmMainUiComponent.startCustomerEmulationSession()` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L394-L418):

- chiama `CsAgentAuthService.startCustomerEmulationSession(customerId)`, che pulisce il token emulato, dispatcha `Logout`, imposta `userId = customerId` e dispatcha `Login` (feature-libs/asm/root/services/csagent-auth.service.ts:L134-L141);
- se `asm.asmSessionSupport.enabled`, crea un evento `{ eventType: 'StartSession' }` (`AsmSessionCreationAction` → `AsmSessionEffects` → POST `asmSessionEvents`: feature-libs/asm/core/store/effects/asm-session.effect.ts:L14-L41, feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L70-L97);
- se riceve `parameters` delega la navigazione ad `AsmDeepLinkService.handleNavigation()` (§3.12). I `parameters` arrivano dal deep link, ma anche dalla selezione cliente, che passa sempre `{ orderId }`: per esempio, dopo una ricerca per numero d'ordine si naviga a `orderDetails` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.html:L109-L112, feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L406-L411, feature-libs/asm/root/services/asm-deep-link.service.ts:L51-L56). Senza `customerId` mostra `asm.error.noCustomerId`.

Quando `isUserLoggedIn()` diventa vero (target `CSAgent` && emulato) lo stream `customer$` chiama `handleCustomerSessionStartRedirection()`, che naviga a `'/'` se la sessione è stata appena avviata (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L166-L175, feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L363-L374).

Fine emulazione (l'agente resta). "End session" in `CustomerEmulationComponent` chiama `authService.logout()` (feature-libs/asm/components/customer-emulation/customer-emulation.component.ts:L69-L71); il percorso standard di logout arriva a `AsmAuthService.coreLogout()` che, essendo in emulazione, pulisce solo token emulato e `userId` senza revoca (feature-libs/asm/root/services/asm-auth.service.ts:L180-L196).

Logout dell'agente. `logoutCustomerSupportAgent()` (feature-libs/asm/root/services/csagent-auth.service.ts:L186-L209) revoca i token, dispatcha l'azione stringa `'[Auth] Logout Customer Support Agent'`, rimette il target a `User`; se era in corso un'emulazione con token emulato (caso in-store) ripristina il token del cliente con `userId = current` e `Login`, altrimenti chiama `authService.logout()`. Il logout è attivato dal pulsante, dalla scadenza del timer di sessione (feature-libs/asm/components/asm-session-timer/asm-session-timer.component.ts:L23-L97) o dal refresh token scaduto (§3.8). Quando `customerSupportAgentLoggedIn$` diventa falso la barra chiude i dialog aperti (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L153-L162).

3.11 Persistenza dello stato ASM

`AsmStatePersistenceService.initSync()` sincronizza con chiave `'asm'` lo stato `{ ui, emulatedUserToken, tokenTarget }` tramite `StatePersistenceService.syncWithStorage`, filtrando le emissioni finché la slice `store.asm` non esiste (la feature potrebbe essere ancora in caricamento) (feature-libs/asm/core/services/asm-state-persistence.service.ts:L48-L87). Il `refresh_token` del token emulato **non** viene persistito "to minimize risk of user account hijacking" (feature-libs/asm/core/services/asm-state-persistence.service.ts:L74-L79). `onRead()` riporta i valori nello store (`AsmUiUpdate`) e nell'`AsmAuthStorageService` (feature-libs/asm/core/services/asm-state-persistence.service.ts:L93-L105). La lettura anticipata nel costruttore di `AsmAuthStorageService` (§3.5) copre la finestra fra bootstrap e lazy load.

3.12 Deep link `assisted-service/emulate?customerId=...`

1. L'URL attiva la UI (`isEmulateInURL`, §3.2).
2. `AsmDeepLinkService` legge i parametri da `winRef.location.search` **una sola volta**, nel costruttore (feature-libs/asm/root/services/asm-deep-link.service.ts:L18-L24); `getParamsInUrl()` scarta le chiavi con valore falsy (feature-libs/asm/root/services/asm-deep-link.service.ts:L69-L79). I parametri sono `customerId`, `orderId`, `ticketId`, `cartId`, `cartType` (feature-libs/asm/root/model/asm.models.ts:L34-L44).

3. `AsmMainUiComponent.subscribeForDeeplink()` naviga a `'/'` ("to avoid 404") solo se l'URL corrente è un deep link di emulazione (`isEmulateInURL()`, feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L283-L286) e, quando l'agente è loggato e c'è `customerId`: se un cliente è già loggato e non è stato emulato via deep link apre la conferma di switch, altrimenti chiama `startSessionWithParameters` in un `setTimeout` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L282-L316).
4. `confirmSwitchCustomer()` carica il cliente target con `userAccountFacade.getById()` e apre `ASM_SWITCH_CUSTOMER`; se è lo stesso cliente si limita a `setEmulatedByDeepLink(true)` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L318-L345). Con `SWITCH` il dialog fa logout del cliente corrente, lasciando che la sottoscrizione del punto 3 avvii la nuova emulazione (feature-libs/asm/components/asm-switch-customer-dialog/asm-switch-customer-dialog.component.ts:L61-L66).
5. Dopo l'avvio, `AsmDeepLinkService.handleNavigation()` naviga con priorità: `cartType==='active'` → `cart`; `cartType==='saved'` + `cartId` → `my-account/saved-cart/<id>`; `orderId` → `orderDetails`; `ticketId` → `supportTicketDetails` (feature-libs/asm/root/services/asm-deep-link.service.ts:L44-L64).
6. `AsmBindCartComponent` reagisce a deep link con `cartType` `inactive`/`active`: nasconde il pulsante bind e memorizza `deepLinkCartId`; solo per `inactive` mostra "save" e precompila il campo cart id; poi mostra l'alert e chiama `handleDeepLinkNavigation()` (feature-libs/asm/components/asm-bind-cart/asm-bind-cart.component.ts:L286-L314, in particolare feature-libs/asm/components/asm-bind-cart/asm-bind-cart.component.ts:L300-L310).

3.13 La barra ASM: orchestrazione in `AsmMainUiComponent`

Oltre a quanto visto, `ngOnInit` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L142-L254):

- se `asmCustomer360` è configurato ne avvia subito il lazy load (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L143-L150);
- osserva lo stato UI: con `status === 403` fa logout agente, `hideUi()` e azzera `status` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L183-L189);
- reagisce alla chiusura dei dialog: con `selectedUser` avvia l'emulazione (e va a `orders` per `ORDER_HISTORY`), con `customerId` (cliente appena creato) emula e torna a `'/'`, poi `ACTIVE_CART` → `cart`, `CUSTOMER_360` → apre il dialog C360; `'forbidden'` → logout + `hideUi()` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L190-L233);
- quando l'agente è loggato, dopo `debounceTime(500)`, lancia una ricerca fittizia `query: 'autoSearchToAvoidUnauthorizedLogin', pageSize: 1` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L235-L251). Lo scopo si ricostruisce dal codice: se l'utente autenticato non ha i permessi da agente, la ricerca fallisce con 403; il reducer `asmUi` fonde l'errore di `CustomerSearchFail` nello stato UI (feature-libs/asm/core/store/reducers/asm-ui.reducer.ts:L21-L26) e il `status: 403` fa scattare il logout descritto sopra.

`hideUi()` nasconde il componente tramite `@HostBinding('class.hidden')`, rimuove `asm_enabled` dal localStorage, chiama `oAuthLibWrapperService.refreshAuthConfig()` e `authService.updateIsUsingASMClient(false)` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L420-L425, feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L113-L113). Il template mostra il login agente se non loggato, `cx-customer-emulation` se c'è un cliente, `cx-customer-selection` altrimenti; tutto nascosto se `collapsed` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.html:L83-L125).

Gli altri componenti in breve:

- `AsmBindCartComponent` (OnPush): valida che il cart id non sia quello attivo; se il carrello attivo del cliente ha articoli apre `ASM_BIND_CART`, altrimenti fa bind diretto e ricarica il carrello corrente (feature-libs/asm/components/asm-bind-cart/asm-bind-cart.component.ts:L77-L179); con `REPLACE` salva il vecchio carrello

come saved cart (feature-libs/asm/components/asm-bind-cart/asm-bind-cart.component.ts:L270-L284). Il bind passa da AsmBindCartService, un Command che usa uid dell'utente corrente (feature-libs/asm/core/facade/asm-bind-cart.service.ts:L23-L45), e da OccAsmAdapter.bindCart(), POST form-urlencoded (feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L188-L217).

- CustomerListComponent: liste clienti via AsmCustomerListService (QueryService per le liste, store per i clienti della lista: feature-libs/asm/core/facade/asm-customer-list.service.ts:L22-L84); chiude con 'forbidden' su 403 (feature-libs/asm/components/customer-list/customer-list.component.ts:L150-L214); startColumnAction() chiude con { actionType, selectedUser } (feature-libs/asm/components/customer-list/customer-list.component.ts:L305-L315).
- AsmCreateCustomerFormComponent: valida i campi, chiama la facade e chiude con l'utente creato; mappa ValidationError e AssistedServiceDuplicatedUidError su chiavi i18n (feature-libs/asm/components/asm-create-customer-form/asm-create-customer-form.component.ts:L82-L190).
- AsmSessionTimerComponent: countdown al secondo, a 0 logout di agente e cliente, reset su navigazione e cambio userId (feature-libs/asm/components/asm-session-timer/asm-session-timer.component.ts:L23-L97).
- I dialog ASM sono inlineRoot: true + DIALOG_TYPE.DIALOG (feature-libs/asm/components/default-bind-cart-layout.config.ts:L14-L22, feature-libs/asm/components/customer-list/default-customer-list-layout.config.ts:L10-L18); i relativi LAUNCH_CALLER sono aggiunti sia a livello di tipo sia a runtime (feature-libs/asm/root/model/augmented-core.model.ts:L9-L23).

3.14 Facade root e lazy loading dei servizi

Le tre facade root (AsmBindCartFacade, AsmCreateCustomerFacade, AsmCustomerListFacade) sono proxy facadeFactory sulla feature ASM_FEATURE (feature-libs/asm/root/facade/asm-bind-cart.facade.ts:L12-L26, feature-libs/asm/root/facade/asm-create-customer.facade.ts:L14-L25, feature-libs/asm/root/facade/asm-customer-list.facade.ts:L14-L39); facadeProviders nel core ASM collega ciascuna facade all'implementazione con useExisting (feature-libs/asm/core/facade/facade-providers.ts:L17-L33). Il proxy connette subito il risultato (connectable + ReplaySubject), quindi il metodo viene eseguito anche senza subscribe e più sottoscrizioni non lo ripetono (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L70-L92). Vedi 20 — Facade, command & query.

3.15 Customer 360

Feature e dipendenze. AsmCustomer360RootModule dichiara featureModules.asmCustomer360.dependencies: [ASM_FEATURE] e l'alias asmCustomer360Core → asmCustomer360 (feature-libs/asm/customer-360/root/asm-customer-360-root.module.ts:L18-L36, nomi in feature-libs/asm/customer-360/root/feature-name.ts:L7-L8). L'app demo carica @spartacus/asm/customer-360 (projects/storefrontapp/src/app/spartacus/features/asm/asm-customer-360-feature.module.ts:L21-L33); AsmCustomer360Module importa core, occ, components e fornisce defaultAsmCustomer360Config (feature-libs/asm/customer-360/asm-customer-360.module.ts:L16-L24). AsmCustomer360CoreModule importa StoreFinderModule per la sezione mappa (feature-libs/asm/customer-360/core/asm-customer-360-core.module.ts:L12-L16).

Configurazione a tab. AsmCustomer360Config (chiave asmCustomer360, feature-libs/asm/customer-360/components/config/asm-customer-360-config.ts:L11-L21) contiene tabs, dateFormat, dateTimeFormat; ogni tab ha i18nNameKey e components, ogni componente { component?, requestData?, config? } (feature-libs/asm/customer-360/root/model/asm-customer-360-tabs-config.ts:L9-L13, feature-libs/asm/customer-360/root/model/asm-customer-360-tab-config.ts:L11-L21). requestData è un AsmCustomer360Query { type?, additionalRequestParameters? }, dove type può essere un AsmCustomer360Type o una stringa qualsiasi (feature-libs/asm/customer-360/root/model/asm-customer-360.model.ts:L243-L258); i 12 tipi standard sono in feature-libs/asm/customer-360/root/model/asm-customer-360.model.ts:L77-L90. Il default definisce 6 tab

(overview, profile, activity, feedback, promotions, store locations) (feature-libs/asm/customer-360/components/config/default-asm-customer-360-config.ts:L21-L142).

Caricamento dati. Il click su Customer 360 apre il dialog `ASM_CUSTOMER_360` passando `{ customer }` (feature-libs/asm/components/customer-emulation/customer-emulation.component.ts:L73-L84); il caller è aggiunto all'enum e mappato su `AsmCustomer360Component` come dialog inline root (feature-libs/asm/customer-360/root/model/augmented-core.model.ts:L9-L15, feature-libs/asm/customer-360/components/default-asm-customer-360-layout.config.ts:L14-L22). Il componente carica separatamente l'overview e i dati della tab corrente (feature-libs/asm/customer-360/components/asm-customer-360/asm-customer-360.component.ts:L116-L164). `setTabData()` chiama `AsmCustomer360Facade.get360Data(currentTab.components)` e mappa ogni componente della tab sull'elemento della risposta con lo stesso `type` (feature-libs/asm/customer-360/components/asm-customer-360/asm-customer-360.component.ts:L267-L294).

La facade è un proxy `facadeFactory` sulla feature `asmCustomer360` (feature-libs/asm/customer-360/root/facade/asm-customer-360.facade.ts:L13-L26). L'implementazione `AsmCustomer360Service` è un `Command` che raccoglie i `requestData` dei componenti e, se ce ne sono, invia **una sola** richiesta con `options.userId = customer.customerId`; altrimenti restituisce `{ value: [] }` (feature-libs/asm/customer-360/core/services/asm-customer-360.service.ts:L33-L73). L'adapter OCC fa POST su `/assistedservicewebservices/${baseSiteId}/users/${userId}/customer360` con body `{ customer360Queries }`, header CS agent e normalizer `ASM_CUSTOMER_360_NORMALIZER` (feature-libs/asm/customer-360/occ/adapters/default-occ-asm-customer-360-config.ts:L9-L18, feature-libs/asm/customer-360/occ/adapters/occ-asm-customer-360.adapter.ts:L54-L89).

Framework delle sezioni. Il template rende ogni componente della tab in `cx-asm-customer-360-section` passando `[component]`, `[config]`, `[data]` e ascoltando `(navigate)` (feature-libs/asm/customer-360/components/asm-customer-360/asm-customer-360.component.html:L195-L205). `AsmCustomer360SectionComponent` fornisce **per istanza** `AsmCustomer360SectionContextSource` (e `AsmCustomer360SectionContext` con `useExisting`), inoltra gli input nei subject della sorgente e rende il componente con `*ngComponentOutlet`; al destroy completa i subject (feature-libs/asm/customer-360/components/sections/asm-customer-360-section/asm-customer-360-section.component.ts:L23-L75, feature-libs/asm/customer-360/components/sections/asm-customer-360-section/asm-customer-360-section.component.html:L1-L1). Il componente di sezione, creato dentro quell'host, inietta il context e legge `data$`, `config$`, scrive su `navigate$` (feature-libs/asm/customer-360/components/sections/asm-customer-360-section-context.model.ts:L14-L29). Esempi: la sezione active cart arricchisce le entry con `ProductService.get(code, ProductScope.DETAILS)` (feature-libs/asm/customer-360/components/sections/asm-customer-360-active-cart/asm-customer-360-active-cart.component.ts:L40-L75); la sezione activity mappa i tipi a rotte ed emette su `navigate$` (feature-libs/asm/customer-360/components/sections/asm-customer-360-activity/asm-customer-360-activity.component.ts:L91-L118); la sezione mappa combina `config$` e `data$` e chiama `storeFinderService.findStoresAction(...)` (feature-libs/asm/customer-360/components/sections/asm-customer-360-map/asm-customer-360-map.component.ts:L61-L91).

Navigazione dalla sezione. `navigate$` → `(navigate)` → `navigateTo()` chiude il dialog con un `AsmDialogActionEvent { actionType: NAVIGATE, route }` (feature-libs/asm/customer-360/components/asm-customer-360/asm-customer-360.component.ts:L218-L225, feature-libs/asm/customer-360/core/utils.ts:L16-L27); `AsmMainUiComponent` lo passa ad `AsmComponentService.handleAsmDialogAction()`, che chiama `routingService.go(route)` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L268-L274, feature-libs/asm/components/services/asm-component.service.ts:L111-L118).

3.16 Installazione via schematics e stili

`addAsmFeatures()` valida l'installazione Spartacus, risolve le dipendenze tra feature con `analyzeCrossFeatureDependencies` ed esegue in catena `analyzeApplication`, `addFeatures`, `addPackageJsonDependenciesForLibrary(peerDependencies, ...)` e `finalizeInstallation` (feature-libs/asm/

schematics/add-asm/index.ts:L25-L43); è registrata sia come `ng-add` sia come `add` (feature-libs/asm/schematics/collection.json:L4-L16). Lo spec copre l'installazione senza feature, il lazy loading, l'assenza dei moduli dipendenti generati, gli stili e l'eager loading (feature-libs/asm/schematics/add-asm/index_spec.ts:L41-L134). Negli stili, `$asm-components-allowlist` contiene sei selettori ripetuti due volte (`cx-asm-toggle-ui`, `cx-csagent-login-form`, `cx-customer-emulation`, `cx-customer-selection`, `cx-dot-spinner`, `cx-customer-list`) (feature-libs/asm/styles/components/_index.scss:L17-L24): il loop `@each` emette quindi due volte lo stesso `@extend`, senza effetti visibili (Sass deduplica l'estensione). DA VERIFICARE: deduplicazione non verificata compilando, `node_modules` assente.

---

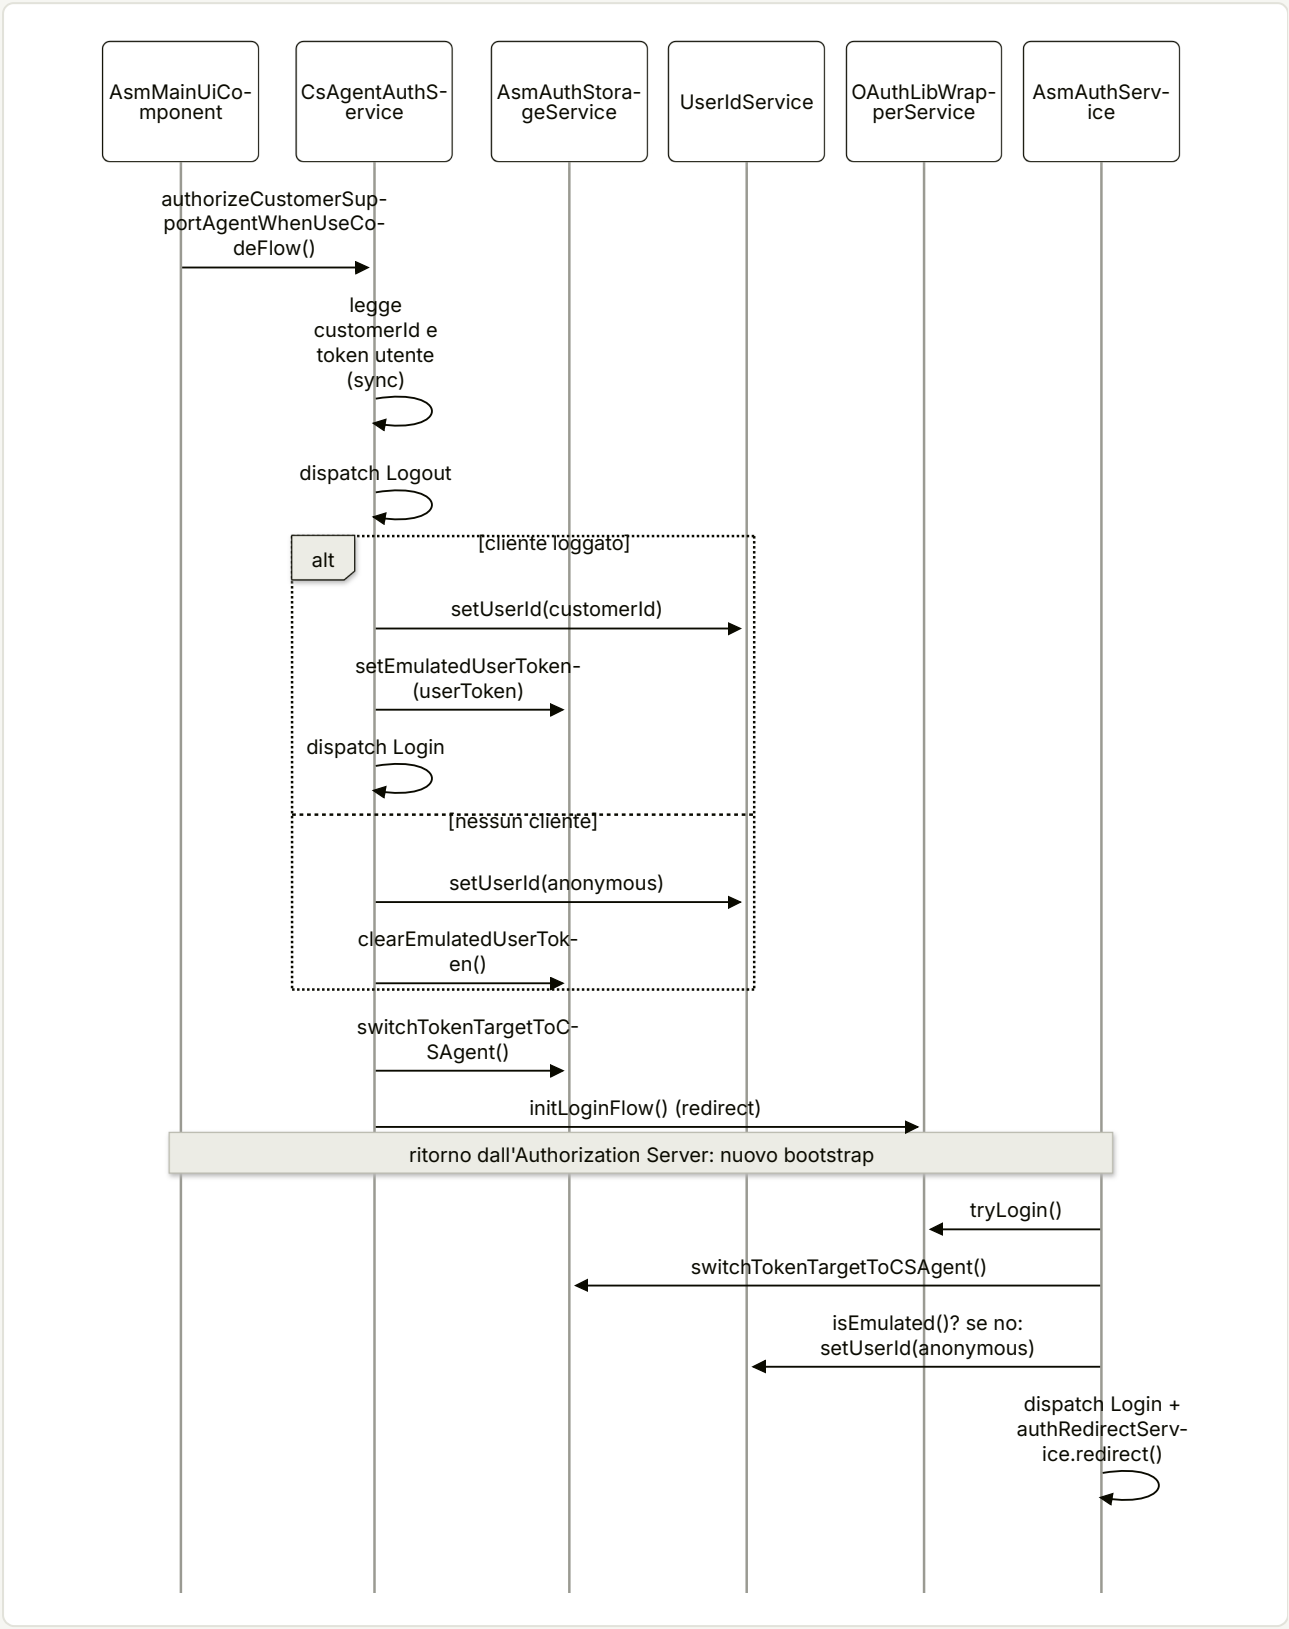
4. Diagrammi

4.1 Bootstrap e attivazione della UI ASM

■ **TAVOLA 29.1** diagramma a tutta pagina, in fondo al capitolo

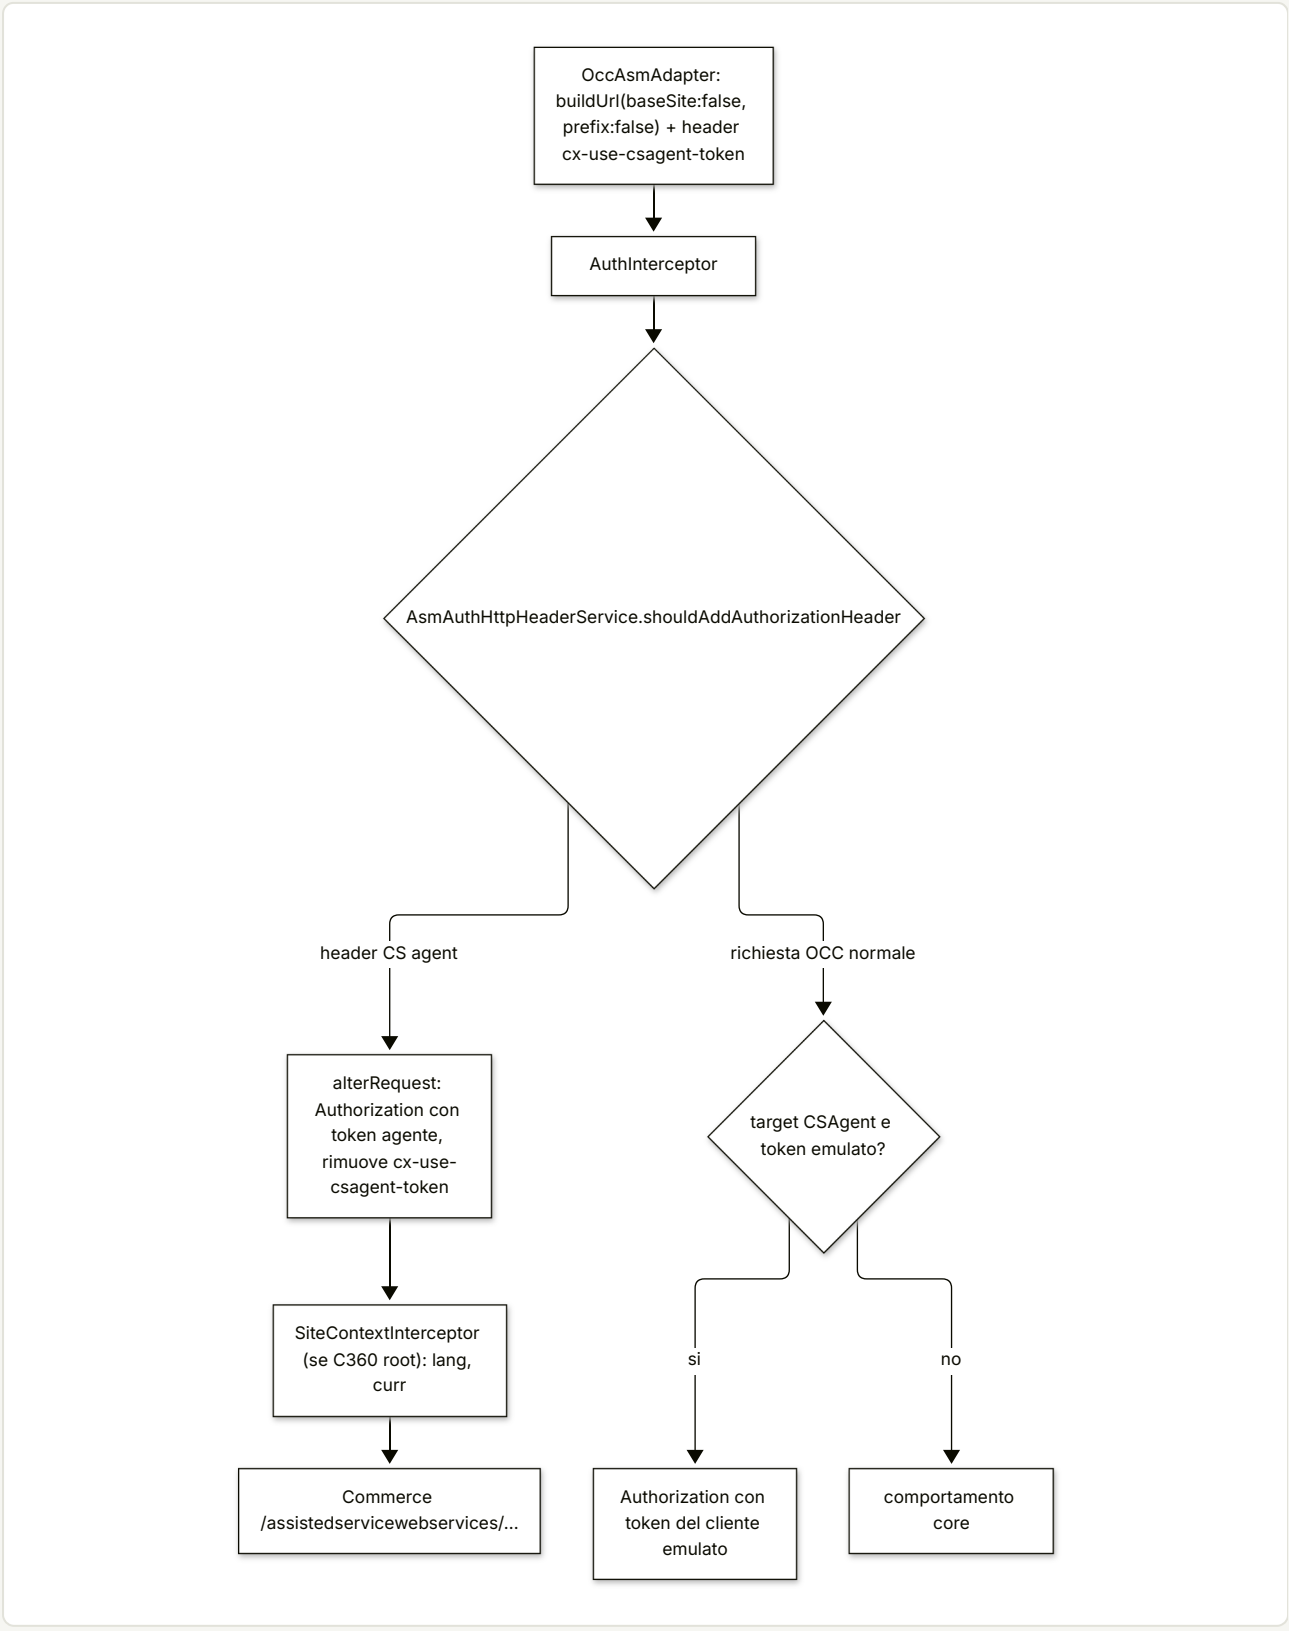
Riferimenti: projects/storefrontapp/src/app/spartacus/features/asm/asm-feature.module.ts:L18-L27, feature-libs/asm/root/asm-root.module.ts:L65-L76, feature-libs/asm/root/services/asm-auth-storage.service.ts:L52-L69, core-libs/core/src/auth/user-auth/user-auth.module.ts:L43-L54, feature-libs/asm/root/asm-loader.module.ts:L16-L40, feature-libs/asm/root/services/asm-enabler.service.ts:L42-L88, feature-libs/asm/core/asm-core.module.ts:L15-L35, core-libs/storefront/layout/launch-dialog/services/outlet-render.strategy.ts:L45-L84.

4.2 Login agente con Authorization Code flow ed emulazione in-store



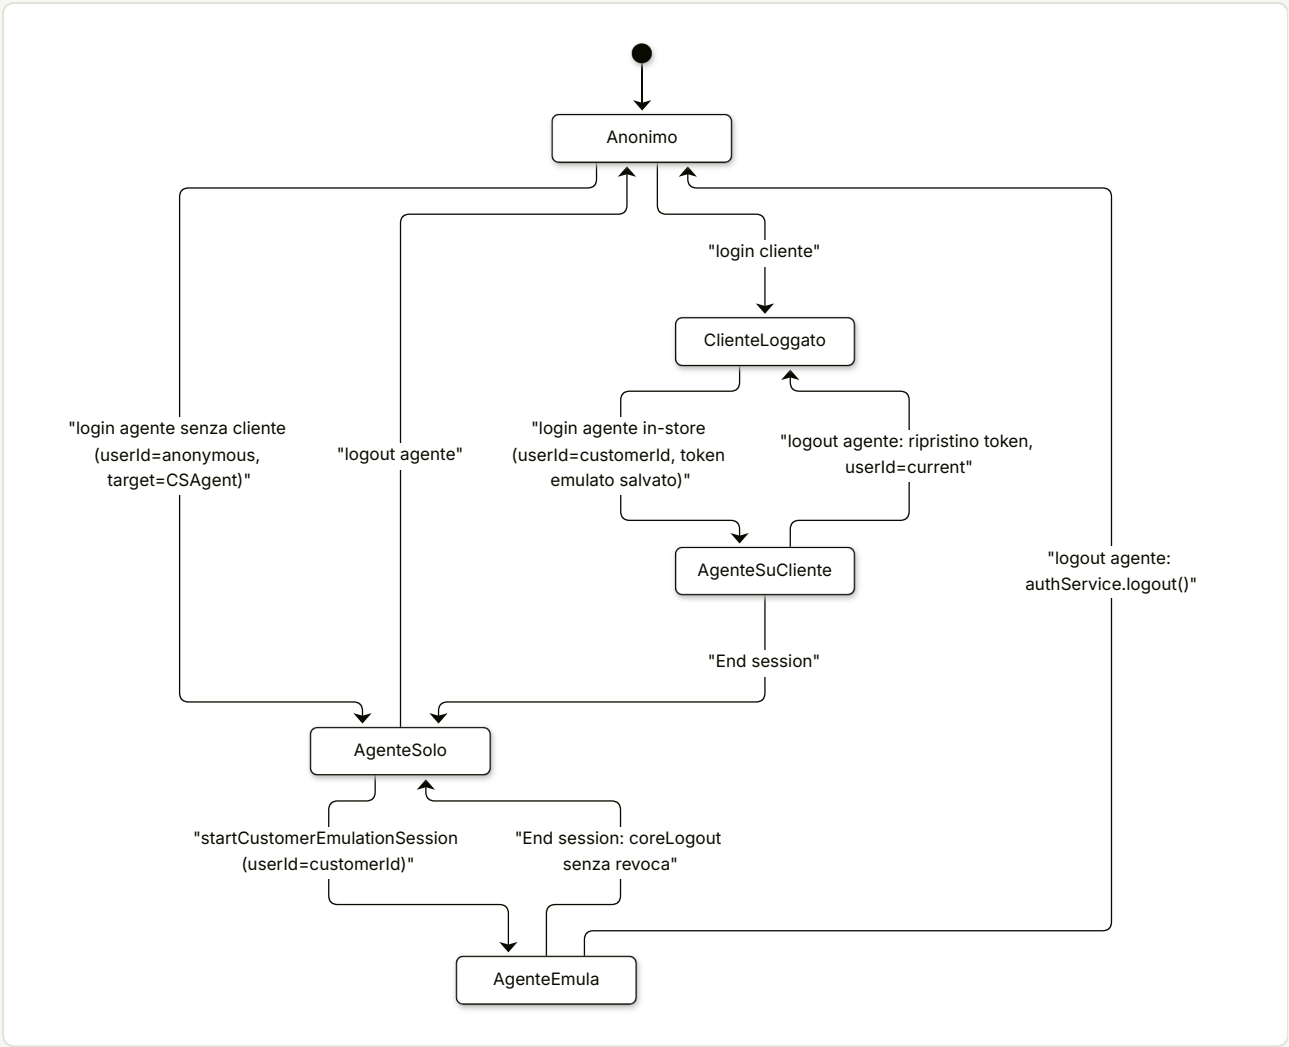
Riferimenti: `feature-libs/asm/root/services/csagent-auth.service.ts:L89-L127`, `feature-libs/asm/root/services/asm-auth.service.ts:L69-L95`.

4.3 Richiesta verso `assistedservicewebservices`



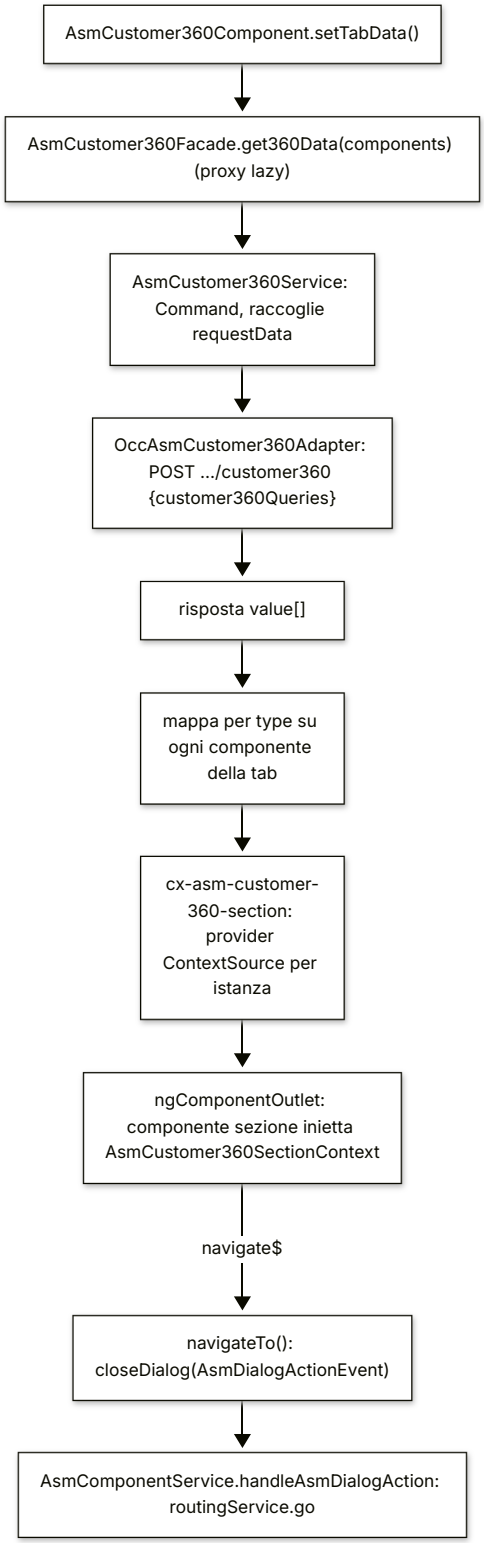
Riferimenti: `feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L99-L121`, `core-libs/core/src/auth/user-auth/http-interceptors/auth.interceptor.ts:L31-L48`, `feature-libs/asm/root/services/asm-auth-http-header.service.ts:L60-L133`, `feature-libs/asm/customer-360/root/interceptors/site-context.interceptor.ts:L54-L72`. L'ordine fra interceptor nel diagramma è illustrativo (vedi NOTA in §3.8).

4.4 Stati di sessione



Riferimenti: `feature-libs/asm/root/services/csagent-auth.service.ts:L46-L84`, `feature-libs/asm/root/services/csagent-auth.service.ts:L134-L141`, `feature-libs/asm/root/services/csagent-auth.service.ts:L186-L209`, `feature-libs/asm/root/services/asm-auth.service.ts:L180-L196`. Nota: "End session" dallo stato AgenteSuCliente passa da `coreLogout()`, che pulisce il token emulato (`feature-libs/asm/root/services/asm-auth.service.ts:L185-L189`): dopo, il logout agente non può più ripristinare il cliente.

4.5 Customer 360: dalla tab alla sezione



Riferimenti: `feature-libs/asm/customer-360/components/asm-customer-360/asm-customer-360.component.ts:L267-L294`, `feature-libs/asm/customer-360/core/services/asm-customer-360.service.ts:L33-L73`, `feature-libs/asm/customer-360/occ/adapters/occ-asm-customer-360.adapter.ts:L54-L89`, `feature-libs/`

asm/customer-360/components/sections/asm-customer-360-section/asm-customer-360-section.component.ts:L23-L75, feature-libs/asm/components/services/asm-component.service.ts:L111-L118.

---

5. Estratti di codice reale

5.1 Initializer non bloccante

feature-libs/asm/root/asm-loader.module.ts:L29-L40

```ts
/**
 *
 * We do not like to block the UI, which is why we delgate loading of ASM
 * to a real component; the router and state aren't available in an optimized
 * way during the APP_INITIALIZER.
 */
export function asmFactory(asmEnablerService: AsmEnablerService): () => void {
  const isReady = () => {
    asmEnablerService.load();
  };
  return isReady;
}
```

5.2 Le tre condizioni di attivazione e il caricamento della UI

feature-libs/asm/root/services/asm-enabler.service.ts:L42-L58

```ts
  isEnabled(): boolean {
    if (this.isLaunched() && !this.isUsedBefore()) {
      if (this.winRef.localStorage) {
        this.winRef.localStorage.setItem(ASM_ENABLED_LOCAL_STORAGE_KEY, 'true');
      }
    }
    return this.isLaunched() || this.isUsedBefore() || this.isEmulateInURL();
  }

  /**
   * Indicates whether ASM is launched through the URL,
   * using the asm flag in the URL.
   */
  protected isLaunched(): boolean {
    const params = this.location.path().split('?')[1];
    return !!params && params.split('&').includes('asm=true');
  }
```

feature-libs/asm/root/services/asm-enabler.service.ts:L84-L88

```ts
protected addUi(): void {
  this.featureModules
    .resolveFeature('asm')
    .subscribe(() => this.launchDialogService.launch(LAUNCH_CALLER.ASM));
}
```

5.3 Route senza path e override dei servizi auth

feature-libs/asm/root/asm-root.module.ts:L38-L76

```ts
  RouterModule.forChild([
    {
      // @ts-ignore
      path: null,
      canActivate: [CmsPageGuard],
      component: PageLayoutComponent,
      data: {
        cxRoute: 'asmDeepLink',
        cxCmsRouteContext: {
          id: HOME_PAGE_CONTEXT,
          type: PageType.CONTENT_PAGE,
        },
      },
    },
  ]),
],
providers: [
  provideDefaultConfig(defaultAsmConfig),
  provideDefaultConfig(<RoutingConfig>{
    routing: {
      routes: {
        asmDeepLink: {
          paths: ['assisted-service/emulate'],
        },
      },
    },
  }),
  {
    provide: AuthStorageService,
    useExisting: AsmAuthStorageService,
  },
  {
    provide: AuthService,
    useExisting: AsmAuthService,
  },
  {
```

```
    provide: AuthHttpHeaderService,
    useExisting: AsmAuthHttpHeaderService,
  },
```

5.4 Login agente con password flow

feature-libs/asm/root/services/csagent-auth.service.ts:L63-L83

```ts
  this.authStorageService.switchTokenTargetToCSAgent();
  try {
    await this.oAuthLibWrapperService.authorizeWithPasswordFlow(
      userId,
      password
    );
    this.store.dispatch(new AuthActions.Logout());

    if (customerId !== undefined && userToken !== undefined) {
      // OCC specific user id handling. Customize when implementing different backend
      this.userIdService.setUserId(customerId);
      this.authStorageService.setEmulatedUserToken(userToken);
      this.store.dispatch(new AuthActions.Login());
    } else {
      // When we can't get the customerId just end all current sessions
      this.userIdService.setUserId(OCC_USER_ID_ANONYMOUS);
      this.authStorageService.clearEmulatedUserToken();
    }
  } catch {
    this.authStorageService.switchTokenTargetToUser();
  }
```

5.5 Emulazione e logout agente

feature-libs/asm/root/services/csagent-auth.service.ts:L134-L141

```ts
public startCustomerEmulationSession(customerId: string): void {
  this.authStorageService.clearEmulatedUserToken();

  // OCC specific user id handling. Customize when implementing different backend
  this.store.dispatch(new AuthActions.Logout());
  this.userIdService.setUserId(customerId);
  this.store.dispatch(new AuthActions.Login());
}
```

feature-libs/asm/root/services/csagent-auth.service.ts:L195-L208

```ts
    await this.oAuthLibWrapperService.revokeAndLogout();

    this.store.dispatch({ type: '[Auth] Logout Customer Support Agent' });
    this.authStorageService.setTokenTarget(TokenTarget.User);

    if (isCustomerEmulated && emulatedToken) {
      this.store.dispatch(new AuthActions.Logout());
      this.authStorageService.setToken(emulatedToken);
      this.userIdService.setUserId(OCC_USER_ID_CURRENT);
      this.authStorageService.clearEmulatedUserToken();
      this.store.dispatch(new AuthActions.Login());
    } else {
      this.authService.logout();
    }
```

5.6 Ritorno dal code flow (CXSPA-13777)

feature-libs/asm/root/services/asm-auth.service.ts:L69-L95

```ts
override async checkOAuthParamsInUrl(): Promise<void> {
  const isUsingASMClient = await firstValueFrom(this.isUsingASMClient());
  if (!isUsingASMClient) {
    await super.checkOAuthParamsInUrl();
    return;
  }

  try {
    const loginResult = await this.oAuthLibWrapperService.tryLogin();
    const token = this.authStorageService.getItem('access_token');

    if (loginResult.result && token && loginResult.tokenReceived) {
      this.authStorageService.switchTokenTargetToCSAgent();
      // The customer userId is restored eagerly from storage before this handler runs
      // (AuthStatePersistenceService). Preserve an emulation started before the code-flow
      // redirect; only anonymize for a pure agent login (no emulation pending) — CXSPA-13777.
      const isEmulated = await firstValueFrom(
        this.userIdService.isEmulated()
      );
      if (!isEmulated) {
        this.userIdService.setUserId(OCC_USER_ID_ANONYMOUS);
      }
      this.store.dispatch(new AuthActions.Login());
      this.authRedirectService.redirect();
    }
  } catch {}
}
```

5.7 "Loggato" per lo storefront

feature-libs/asm/root/services/asm-auth.service.ts:L201-L214

```ts
isUserLoggedIn(): Observable<boolean> {
  return combineLatest([
    this.authStorageService.getToken(),
    this.userIdService.isEmulated(),
    this.authStorageService.getTokenTarget(),
  ]).pipe(
    map(
      ([token, isEmulated, tokenTarget]) =>
        Boolean(token?.access_token) &&
        (tokenTarget === TokenTarget.User ||
          (tokenTarget === TokenTarget.CSAgent && isEmulated))
    )
  );
}
```

5.8 Header CS agent e token emulato

feature-libs/asm/root/services/asm-auth-http-header.service.ts:L84-L133

```ts
public alterRequest(
  request: HttpRequest<any>,
  token?: AuthToken
): HttpRequest<any> {
  const hasAuthorizationHeader = !!this.getAuthorizationHeader(request);
  const isCSAgentRequest = this.isCSAgentTokenRequest(request);
  const tokenForRequest = this.getTokenForRequest(request, token);

  let req = super.alterRequest(request, tokenForRequest);

  if (!hasAuthorizationHeader && isCSAgentRequest) {
    req = request.clone({
      setHeaders: {
        ...this.createAuthorizationHeader(tokenForRequest),
      },
    });
    return InterceptorUtil.removeHeader(
      USE_CUSTOMER_SUPPORT_AGENT_TOKEN,
      req
    );
  }
  return req;
}

protected getTokenForRequest(
  request: HttpRequest<any>,
```

```
    token?: AuthToken
  ): AuthToken | undefined {
    if (this.shouldUseEmulatedUserToken(request)) {
      return this.authStorageService.getEmulatedUserToken();
    }
    return token;
  }

  protected shouldUseEmulatedUserToken(request: HttpRequest<any>): boolean {
    if (this.isCSAgentTokenRequest(request)) {
      return false;
    }

    let tokenTarget: TokenTarget | undefined;
    this.authStorageService
      .getTokenTarget()
      .subscribe((target) => (tokenTarget = target))
      .unsubscribe();

    return Boolean(
      tokenTarget === TokenTarget.CSAgent &&
        this.authStorageService.getEmulatedUserToken()?.access_token
    );
  }
```

5.9 Interceptor `sap-commerce-cloud-user-id`

feature-libs/asm/root/interceptors/user-id-http-header.interceptor.ts:L48-L69

```ts
    // Casting as <AsmConfig> to avoid circular dependencies with @spartacus/asm/core.
    if (!(<AsmConfig>this.config).asm?.userIdHttpHeader?.enable) {
      return next.handle(httpRequest);
    }

    const asmContext = httpRequest.context.get(OCC_HTTP_TOKEN);

    let userIdObservable: Observable<string | undefined>;

    if (typeof asmContext.sendUserIdAsHeader === 'string') {
      userIdObservable = of(asmContext.sendUserIdAsHeader);
    } else if (asmContext.sendUserIdAsHeader) {
      userIdObservable = this.userIdService
        .takeUserId()
        .pipe(
          map((userId) =>
            this.uniqueUserIdConstants.has(userId) ? undefined : userId
          )
        );
```

```
    } else {
      return next.handle(httpRequest);
    }
```

5.10 Adapter OCC: fuori dal prefisso e con marker CS agent

feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L99-L121

```ts
  protected getHeaders(): HttpHeaders {
    return InterceptorUtil.createHeader(
      USE_CUSTOMER_SUPPORT_AGENT_TOKEN,
      true,
      new HttpHeaders()
    );
  }

  customerLists(): Observable<CustomerListsPage> {
    const headers = this.getHeaders();
    const params: HttpParams = new HttpParams().set(
      'baseSite',
      this.activeBaseSite
    );

    const url = this.occEndpointsService.buildUrl(
      'asmCustomerLists',
      {},
      {
        baseSite: false,
        prefix: false,
      }
    );
```

5.11 Reducer UI che assorbe l'errore e meta-reducer di logout

feature-libs/asm/core/store/reducers/asm-ui.reducer.ts:L13-L31

```ts
export function reducer(state: AsmUi = initialState, action: Action): AsmUi {
  switch (action.type) {
    case AsmActions.ASM_UI_UPDATE: {
      return {
        ...state,
        ...(action as AsmActions.AsmUiUpdate).payload,
      };
    }
    case AsmActions.CUSTOMER_SEARCH_FAIL: {
      return {
        ...state,
```

```
        ...(action as AsmActions.CustomerSearchFail).payload,
      };
    }
    default: {
      return state;
    }
  }
}
```

feature-libs/asm/core/store/reducers/index.ts:L44-L56

```ts
export function clearCustomerSupportAgentAsmState(
  reducer: ActionReducer<AsmState, Action>
): ActionReducer<AsmState, Action> {
  return function (state: AsmState | undefined, action: Action) {
    if (action.type === AsmActions.LOGOUT_CUSTOMER_SUPPORT_AGENT) {
      state = {
        ...(state as AsmState),
        customerSearchResult: {} as StateUtils.LoaderState<CustomerSearchPage>,
      };
    }
    return reducer(state, action);
  };
}
```

5.12 Persistenza senza `refresh_token`

feature-libs/asm/core/services/asm-state-persistence.service.ts:L62-L87

```ts
  protected getAsmState(): Observable<SyncedAsmState> {
    return combineLatest([
      this.store.pipe(
        // Since getAsmState() may be called while the module is lazy loaded
        // The asm state slice may not exist yet in the first store emissions.
        filter((store) => !!store.asm),
        select(AsmSelectors.getAsmUi)
      ),
      this.authStorageService.getEmulatedUserTokenState(),
      this.authStorageService.getTokenTarget(),
    ]).pipe(
      map(([ui, emulatedUserToken, tokenTarget]) => {
        let emulatedToken = emulatedUserToken;
        if (emulatedToken) {
          emulatedToken = { ...emulatedUserToken } as AuthToken;
          // To minimize risk of user account hijacking we don't persist emulated user refresh_token
          delete emulatedToken.refresh_token;
        }
        return {
```

```
        ui,
        emulatedUserToken: emulatedToken,
        tokenTarget,
      };
    })
  );
}
```

5.13 Customer 360: una richiesta per tab

feature-libs/asm/customer-360/core/services/asm-customer-360.service.ts:L33-L66

```ts
this.asmCustomer360Command$ = this.commandService.create(
  (tabComponents) => {
    return this.userAccountFacade.get().pipe(
      take(1),
      concatMap((customer) => {
        const queries = tabComponents.reduce(
          (requests: Array<AsmCustomer360Query>, component) => {
            if (component.requestData) {
              return requests.concat(component.requestData);
            }
            return requests;
          },
          []
        );

        if (queries.length > 0) {
          const request: AsmCustomer360Request = {
            queries,
            options: {
              userId: customer?.customerId ?? '',
            },
          };
          return this.asmCustomer360Connector.getAsmCustomer360Data(
            request
          );
        } else {
          return of({
            value: [],
          });
        }
      })
    );
  }
);
```

5.14 Host di sezione con context per istanza

feature-libs/asm/customer-360/components/sections/asm-customer-360-section/asm-customer-360-section.component.ts:L23-L52

```ts
@Component({
  selector: 'cx-asm-customer-360-section',
  templateUrl: './asm-customer-360-section.component.html',
  providers: [
    AsmCustomer360SectionContextSource,
    {
      provide: AsmCustomer360SectionContext,
      useExisting: AsmCustomer360SectionContextSource,
    },
  ],
  imports: [NgComponentOutlet],
})
export class AsmCustomer360SectionComponent implements OnDestroy {
  @Input()
  component: Type<unknown>;

  @Input()
  set customer(customer: User) {
    this.source.customer$.next(customer);
  }

  @Input()
  set config(config: AsmCustomer360SectionConfig) {
    this.source.config$.next(config);
  }

  @Input()
  set data(data: Observable<unknown>) {
    this.source.data$.next(data);
  }
```

6. Configurazione

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN

7. Commenti e note notevoli dal sorgente

- "The ASM loader module takes care of loading the ASM UI only in case there's a reason to do so." e la motivazione del non-blocco del bootstrap — `feature-libs/asm/root/asm-loader.module.ts:L12-L34`.
- "This service is added to avoid any polution of the UI and runtime performance for the ordinary production user." — `feature-libs/asm/root/services/asm-enabler.service.ts:L13-L17`.
- "The providers below preserve backward compatibility for the CXSPA-12514 fix and should be removed once the enableExpiredRefreshTokenHandlers feature toggle is fully rolled out." — `feature-libs/asm/root/asm-root.module.ts:L77-L79`.
- "// OCC specific user id handling. Customize when implementing different backend" (tre occorrenze): l'emulazione è un dettaglio OCC — `feature-libs/asm/root/services/csagent-auth.service.ts:L72-L72`, `feature-libs/asm/root/services/csagent-auth.service.ts:L110-L110`, `feature-libs/asm/root/services/csagent-auth.service.ts:L137-L137`.
- "isEmulated is set to true before switchTokenTargetToCSAgent() so that isUserLoggedIn() stays true throughout and no spurious LogoutEvent fires." — `feature-libs/asm/root/services/csagent-auth.service.ts:L111-L112`.
- "// TODO(#8248): Create new loading state outside of store": `getCustomerSupportAgentTokenLoading()` ritorna sempre `of(false)` — `feature-libs/asm/root/services/csagent-auth.service.ts:L178-L181`.
- CXSPA-13777: "Preserve an emulation started before the code-flow redirect; only anonymize for a pure agent login" — `feature-libs/asm/root/services/asm-auth.service.ts:L82-L84`.

- Refuso nel JSDoc di `AsmAuthService`: "working for both user na CS agent" — `feature-libs/asm/root/services/asm-auth.service.ts:L34-L37`.
- "When we start emulation from the UI (not by ASM login) we can't restore user session on cs agent logout. Only available solution is to drop session we could restore, to avoid account hijack." — `feature-libs/asm/root/services/asm-auth-storage.service.ts:L132-L138`.
- "To minimize risk of user account hijacking we don't persist emulated user refresh_token" — `feature-libs/asm/core/services/asm-state-persistence.service.ts:L77-L77`.
- `AsmComponentService.unload()` ammette che rimuove solo lo storage e non la UI dal DOM perché "outlets currently do not support this" — `feature-libs/asm/components/services/asm-component.service.ts:L76-L82`.
- "//Always route to home page to avoid 404" — `feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L284-L285`.
- "// TODO(#12660): Remove default value once backend is updated" (descrizione `'-'` del saved cart creato dal bind) — `feature-libs/asm/components/asm-bind-cart/asm-bind-cart.component.ts:L279-L280`.
- Il JSDoc dell'interceptor cita "OCC_ASM_TOKEN", ma il codice usa `OCC_HTTP_TOKEN` — `feature-libs/asm/root/interceptors/user-id-http-header.interceptor.ts:L25-L28`.
- JSDoc di `AsmService.createAsmSessionEvent` copiato erroneamente ("Get the state of the ASM UI") — `feature-libs/asm/core/facade/asm.service.ts:L71-L78`.
- L'azione di logout agente dice "Used to clear store data (ui, search results)", ma il meta-reducer pulisce solo i risultati di ricerca — `feature-libs/asm/core/store/actions/logout-agent.action.ts:L12-L14`, `feature-libs/asm/core/store/reducers/index.ts:L48-L53`.

---

8. Extension point

EXTENSION POINT	COME	EXPORT	RICETTA
`AsmConfig` (timer, ricerca, colonne customer list, header user id, session event, create customer)	`provideConfig({ asm: {...} })`	`@spartacus/asm/root` (`feature-libs/asm/root/public_api.ts:L7-L7`)	50 — Ricette config e DI
Servizi auth ASM (`AsmAuthService`, `AsmAuthStorageService`, `AsmAuthHttpHeaderService`, `CsAgentAuthService`, `AsmEnablerService`, `AsmDeepLinkService`, `AsmProtectedRoutesService`)	sottoclasse + provider (vedi nota sotto)	`@spartacus/asm/root` (`feature-libs/asm/root/services/index.ts:L7-L13`)	50 — Ricette config e DI
`AsmAdapter` / `OccAsmAdapter`, normalizer `CUSTOMER_SEARCH_PAGE_NORMALIZER`, `CUSTOMER_LISTS_NORMALIZER`, endpoint `asm*`	adapter custom, converter multi, override `backend.occ.endpoints`	`@spartacus/asm/core` (`feature-libs/asm/core/connectors/asm.adapter.ts:L18-L47`, `feature-libs/asm/core/connectors/converters.ts:L11-L17`), `@spartacus/asm/occ`	52 — Ricette OCC
Layout `launch.ASM*` (outlet/dialog dei componenti)	`provideConfig(<LayoutConfig>{ launch: {...} })`	via config	51 — Ricette CMS, outlet, layout

EXTENSION POINT	COME	EXPORT	RICETTA
Componenti UI ASM e `AsmComponentService`	sostituzione del componente nella config `launch`	`@spartacus/asm/components` (feature-libs/asm/components/public_api.ts:L7-L22)	51 — Ricette CMS, outlet, layout
Tab e sezioni Customer 360	`provideConfig({ asmCustomer360: { tabs: [...] } })`, `requestData.type` stringa custom	`@spartacus/asm/customer-360/root` e `/components` (feature-libs/asm/customer-360/components/public_api.ts:L7-L11)	53 — Feature lazy, i18n
`AsmCustomer360Adapter` / `ASM_CUSTOMER_360_NORMALIZER`	adapter o converter custom	`@spartacus/asm/customer-360/core`	52 — Ricette OCC
Traduzioni `asm`, `asmCustomer360`	`i18n.resources` + chunk	`@spartacus/asm/assets`, `@spartacus/asm/customer-360/assets`	53 — Feature lazy, i18n
Store (`AsmActions`, `AsmSelectors`, `StateWithAsm`)	dispatch/select	`@spartacus/asm/core` (feature-libs/asm/core/public_api.ts:L11-L13); effects e reducer **non** esportati	54 — Upgrade-safe

Override dei servizi auth. `AsmRootModule` registra `{ provide: AuthService, useExisting: AsmAuthService }` ecc. (feature-libs/asm/root/asm-root.module.ts:L65-L87). Per sostituire, ad esempio, `AsmAuthService` con una sottoclasse conviene fornire il proprio servizio sul token `AsmAuthService` (così anche il `useExisting` del core lo segue) — esempio illustrativo, non presente nel repo:

```ts
// esempio (non nel repo): simboli esportati da @spartacus/asm/root
@Injectable({ providedIn: 'root' })
export class MyAsmAuthService extends AsmAuthService { /* ... */ }

providers: [{ provide: AsmAuthService, useExisting: MyAsmAuthService }]
```

> DA VERIFICARE — L'effetto dipende dall'ordine dei provider nell'injector root (il proprio provider deve vincere su quello `providedIn: 'root'` di `AsmAuthService`); non è stato verificato in un'app in esecuzione (`node_modules` assente).

Colonne della customer list. `asm.customerList.columns` è un array (per la semantica del merge di array nella config vedi 11 — Configurazione); i tipi di azione disponibili sono quelli di `CustomerListColumnActionType` (feature-libs/asm/root/model/customer-list.model.ts:L28-L33), interpretati in `AsmMainUiComponent` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L190-L233).

Sezioni Customer 360 custom: limite. Una sezione custom dovrebbe iniettare `AsmCustomer360SectionContext`, ma la classe **non è esportata**: l'index delle sezioni esporta solo le 11 sezioni (feature-libs/asm/customer-360/components/sections/index.ts:L7-L17). Si può configurare una tab che riusa le sezioni standard, oppure un componente che non usa il context (ricevendo però i dati solo tramite il context, cioè di fatto nulla). Questo è un vincolo di API pubblica: vedi 54 — API pubblica vs interna.

Interceptor non esportati. `UserIdHttpHeaderInterceptor` e `SiteContextInterceptor` non sono esportati dai rispettivi `public_api.ts` (feature-libs/asm/root/public_api.ts:L7-L14, feature-libs/asm/customer-360/root/public_api.ts:L7-L10): per disattivare l'header user id si usa la config `asm.userIdHttpHeader.enable: false`.

9. Trappole, casi limite, comportamenti controintuitivi

1. **Due copie della logica "ASM abilitato".** `AsmEnablerService` (root) e `AuthService` (core) duplicano letterali `'asm_enabled'`, `'asm=true'`, `'assisted-service/emulate?'`: cambiarne una non cambia l'altra — feature-libs/asm/root/services/asm-enabler.service.ts:L42-L79, core-libs/core/src/auth/user-auth/facade/auth.service.ts:L263-L295.
2. `asm=true` **esatto.** `asm=TRUE` o `?asm` non attivano — feature-libs/asm/root/services/asm-enabler.service.ts:L55-L58.
3. **La route del deep link ha** `path: null`**.** Il path vero viene dalla `RoutingConfig` `asmDeepLink`: cercarlo nella definizione Angular è inutile — feature-libs/asm/root/asm-root.module.ts:L38-L51.
4. **Il 403 arriva alla UI passando per il reducer** `asmUi`**.** `CustomerSearchFail` fonde l'intero errore nello stato UI; `AsmMainUiComponent` vede `status: 403`, fa logout e lo azzera — feature-libs/asm/core/store/reducers/asm-ui.reducer.ts:L21-L26, feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L183-L188. Insieme alla ricerca fittizia `autoSearchToAvoidUnauthorizedLogin` è il meccanismo che espelle chi non è agente (§3.13).
5. **Default** `pagination` **globale.** `AsmComponentsModule` fornisce `defaultAsmPaginationConfig` con `provideDefaultConfig` (feature-libs/asm/components/asm-components.module.ts:L97-L105), cioè un `DefaultConfigChunk` (core-libs/core/src/config/config-providers.ts:L55-L61). Al lazy load, `ConfigurationService` lo fonde nella config ambient e poi in-place nella config globale, sopra i default root e sotto la config dell'app (core-libs/core/src/config/services/configuration.service.ts:L76-L106). Il default storefront ha `addStart: true, addEnd: true` (core-libs/storefront/shared/components/list-navigation/pagination/config/default-pagination.config.ts:L9-L14), ASM `false`; `PaginationConfig` è `useExisting: Config` e il builder rilegge la config a ogni accesso (core-libs/storefront/shared/components/list-navigation/pagination/config/pagination.config.ts:L11-L17, core-libs/storefront/shared/components/list-navigation/pagination/pagination.builder.ts:L370-L375). Dedotto dal codice: dopo l'apertura della barra ASM anche le paginazioni non-ASM cambiano aspetto, a meno che l'app configuri `pagination` esplicitamente. `DA VERIFICARE` a runtime (dipende anche da `disableConfigUpdates`, core-libs/core/src/config/services/configuration.service.ts:L102-L105).
6. **Meta-reducer parziale.** Il logout agente azzera solo `customerSearchResult`, non la lista clienti né `asmUi`, malgrado il JSDoc — feature-libs/asm/core/store/reducers/index.ts:L44-L56, feature-libs/asm/core/store/actions/logout-agent.action.ts:L12-L14.
7. **Azione come oggetto letterale.** `CsAgentAuthService` dispatcha `{ type: '[Auth] Logout Customer Support Agent' }` invece della classe `LogoutCustomerSupportAgent` (presumibilmente per non far dipendere il root dal core ASM, come dichiara il commento sulle dipendenze circolari in feature-libs/asm/root/interceptors/user-id-http-header.interceptor.ts:L48-L48); il meta-reducer confronta solo `type` — feature-libs/asm/root/services/csagent-auth.service.ts:L197-L197, feature-libs/asm/core/store/actions/logout-agent.action.ts:L9-L17.
8. **Bind cart con** `uid`**, non** `customerId` — feature-libs/asm/core/facade/asm-bind-cart.service.ts:L26-L38. E `AsmBindCartService` non è esportato da `@spartacus/asm/core` — feature-libs/asm/core/facade/index.ts:L7-L9.
9. `OccAsmAdapter` **ignora** `currentPage` (usa solo `page`) e non usa la `AsmConfig` iniettata — feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L131-L176, feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L54-L60.
10. **Base site e user id "ultimo noto".** `OccAsmAdapter` e `OccAsmCustomer360Adapter` memorizzano `activeBaseSite`/`currentUserId` da sottoscrizioni aperte nel costruttore e mai chiuse — feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L61-L67, feature-libs/asm/customer-360/occ/adapters/occ-asm-customer-360.adapter.ts:L41-L43.

11. **Endpoint senza slash.** `asmSessionEvent` non inizia con `/`, a differenza degli altri — feature-libs/asm/occ/adapters/default-occ-asm-config.ts:L13-L18.
12. **Mutazione della config globale.** `CustomerListComponent.updateCustomerListColumns()` modifica in-place gli oggetti colonna (`headerLocalizationKey = 'hideHeaders'`), e la modifica persiste fra aperture del dialog — feature-libs/asm/components/customer-list/customer-list.component.ts:L257-L279.
13. **Context C360 mai alimentato in parte.** Il padre non lega l'input `customer` della sezione, quindi `context.customer$` non emette; `savedCarts$`, `activeCart$`, `orderHistory$` non sono mai alimentati — feature-libs/asm/customer-360/components/asm-customer-360/asm-customer-360.component.html:L198-L204, feature-libs/asm/customer-360/components/sections/asm-customer-360-section-context-source.model.ts:L20-L32. Inoltre `data` è tipato `Observable<unknown>` ma riceve un oggetto — feature-libs/asm/customer-360/components/sections/asm-customer-360-section/asm-customer-360-section.component.ts:L49-L52.
14. **Chiave i18n con case diverso.** Il template usa `asmCustomer360.header.newSubtitle`, il JSON en ha `newSubTitle` — feature-libs/asm/customer-360/components/asm-customer-360/asm-customer-360.component.html:L15-L19, feature-libs/asm/customer-360/assets/translations/en/asmCustomer360.json:L8-L10.
15. **Letture sincrone con `subscribe().unsubscribe()`.** Funzionano solo perché le sorgenti sono `BehaviorSubject`/store sincroni; un override che le rende asincrone rompe login e logout — feature-libs/asm/root/services/csagent-auth.service.ts:L53-L61, feature-libs/asm/root/services/asm-auth.service.ts:L98-L111.
16. **Errori inghiottiti.** `AsmAuthService.checkOAuthParamsInUrl()` ha un `catch {}` vuoto: un fallimento del ritorno dal code flow ASM non lascia traccia — feature-libs/asm/root/services/asm-auth.service.ts:L76-L94.
17. **"End session" dopo un login in-store perde il cliente.** `coreLogout()` in emulazione pulisce il token emulato, per cui il successivo logout agente non può più ripristinare la sessione del cliente — feature-libs/asm/root/services/asm-auth.service.ts:L185-L189, feature-libs/asm/root/services/csagent-auth.service.ts:L200-L208.
18. **Sottoscrizioni che si accumulano.** `showC360Dialog()` aggiunge una nuova sottoscrizione a `dialogClose` a ogni apertura; la sottoscrizione al 403 in `ngOnInit` non è mai chiusa — feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L256-L275, feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L183-L189.
19. **Timer che non riparte.** Il reset del timer di sessione avviene solo se `timeLeft > 0` — feature-libs/asm/components/asm-session-timer/asm-session-timer.component.ts:L77-L81.
20. **La UI non sparisce davvero.** `hideUi()` aggiunge la classe `hidden` e rimuove lo storage, ma il componente resta nell'outlet — feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L420-L425, feature-libs/asm/components/services/asm-component.service.ts:L76-L82.
21. **Versione nel `package.json`.** `feature-libs/asm/package.json` dichiara `221121.22.0`, non `2612.0.0` — feature-libs/asm/package.json:L3-L3.

---

10. Come fare debug

- **La barra non compare.** Controlla le tre condizioni (§3.2): `asm=true` esatto nella query, `localStorage.asm_enabled`, URL di deep link. Verifica che la feature `asm` sia configurata in `featureModules` (projects/storefrontapp/src/app/spartacus/features/asm/asm-feature.module.ts:L21-L27) e che esista `launch.ASM` (in dev mode `LaunchDialogService` logga "No configuration provided for caller", core-libs/storefront/

layout/launch-dialog/services/launch-dialog.service.ts:L94-L96). Per "dimenticare" ASM: rimuovi `asm_enabled` e la chiave `asm` dallo storage.

- **Il login agente porta al login cliente (o viceversa).** Verifica il valore di `authorizationCodeFlowByDefault` e se, dopo il redirect, `isUsingASMClient` è vero: lo imposta `refreshAuthConfig()` solo se il core rileva ASM con la propria logica (core-libs/core/src/auth/user-auth/facade/auth.service.ts:L263-L327). Con il client ASM, `AsmAuthService.checkOAuthParamsInUrl()` è l'unico che processa il callback e inghiotte gli errori (feature-libs/asm/root/services/asm-auth.service.ts:L76-L94): un breakpoint lì è il primo passo.
- **Lo stato della sessione.** Con un breakpoint in `AsmAuthStorageService` leggi `_tokenTarget$.value` e `getEmulatedUserToken()`; in `UserIdService` lo `userId` (`anonymous`/`current`/customerId). La tabella della §3.5 dice cosa ci si deve aspettare in ogni stato.
- **Richieste ASM 401/CORS.** Nel tab Network le chiamate a `/assistedservicewebservices/` devono avere `Authorization` e **non** avere `cx-use-csagent-token` (rimosso in feature-libs/asm/root/services/asm-auth-http-header.service.ts:L94-L104). Se compare `sap-commerce-cloud-user-id` e il backend lo rifiuta in CORS, disattiva `asm.userIdHttpHeader.enable` (feature-libs/asm/root/config/asm-config.ts:L39-L50). Con C360 configurato le stesse richieste hanno `lang` e `curr` in query.
- **Logout "inspiegabile" subito dopo il login.** Probabile 403 sulla ricerca fittizia (`autoSearchToAvoidUnauthorizedLogin`, feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L235-L251): l'utente non ha il gruppo agente in Commerce. Con Redux DevTools cerca `[Asm] Customer Search Fail`: nel diff della stessa azione `asm.asmUi.status` diventa `403` (feature-libs/asm/core/store/reducers/asm-ui.reducer.ts:L21-L26); subito dopo `AsmMainUiComponent` fa logout e dispatcha `[Asm] UI Update` con `status: undefined` (feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L183-L188).
- **Store.** Slice `asm` (`customerSearchResult`, `customerListCustomersSearchResult`, `asmUi`), azioni di ricerca `[Asm] ...` (feature-libs/asm/core/store/actions/customer.action.ts:L14-L26) e `'[Auth] Logout Customer Support Agent'` (feature-libs/asm/core/store/actions/logout-agent.action.ts:L9-L10). La slice esiste solo dopo il lazy load.
- **Customer 360 vuoto.** Verifica che la feature `asmCustomer360` sia configurata (altrimenti il pulsante non appare e la colonna è nascosta: feature-libs/asm/components/customer-list/customer-list.component.ts:L234-L279), che il body della POST `.../customer360` contenga i `type` attesi e che la risposta li restituisca con lo stesso `type` (il match è per uguaglianza, feature-libs/asm/customer-360/components/asm-customer-360/asm-customer-360.component.ts:L282-L291).

---

11. Domande di autoverifica

1. **Perché `AsmRootModule` è eager se tutta la UI è lazy?** Perché deve sostituire i servizi auth del core (`AuthStorageService`, `AuthService`, `AuthHttpHeaderService`, `ProtectedRoutesService`) e registrare l'interceptor prima di qualsiasi richiesta, oltre a fornire config di default e route del deep link — feature-libs/asm/root/asm-root.module.ts:L34-L95.
2. **Quali sono le tre condizioni che attivano la barra ASM?** `asm=true` come parametro esatto, `localStorage.asm_enabled === 'true'`, URL contenente `assisted-service/emulate?` — feature-libs/asm/root/services/asm-enabler.service.ts:L42-L79.
3. **Come fa lo storefront a considerare "loggato" un cliente mentre il token è dell'agente?** `AsmAuthService.isUserLoggedIn()` è vero anche con target `CSAgent` se lo `userId` è emulato (né `anonymous` né `current`) — feature-libs/asm/root/services/asm-auth.service.ts:L201-L214, core-libs/core/src/auth/user-auth/facade/user-id.service.ts:L81-L88.

4. **Che cosa succede alle richieste OCC "normali" se l'agente fa login mentre un cliente è già loggato?** Con target `CSAgent` e un token emulato con `access_token`, `AsmAuthHttpHeaderService` usa il token del cliente per le richieste non marcate CS agent — feature-libs/asm/root/services/asm-auth-http-header.service.ts:L108-L133.
5. **Perché nel code flow lo stato di emulazione è persistito prima di `initLoginFlow()`?** Perché `initLoginFlow()` fa un redirect a pagina intera e il codice successivo non gira in modo affidabile; il token agente arriva poi in `AsmAuthService.checkOAuthParamsInUrl()`, che non anonimizza se un'emulazione è pendente — feature-libs/asm/root/services/csagent-auth.service.ts:L103-L123, feature-libs/asm/root/services/asm-auth.service.ts:L80-L91.
6. **Come viene espulso dalla barra un utente autenticato che non è un agente?** Dopo il login la barra lancia una ricerca fittizia; il 403 produce `CustomerSearchFail`, il reducer `asmUi` fonde `status: 403` nello stato UI e `AsmMainUiComponent` fa logout e `hideUi()` — feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L235-L251, feature-libs/asm/core/store/reducers/asm-ui.reducer.ts:L21-L26, feature-libs/asm/components/asm-main-ui/asm-main-ui.component.ts:L183-L189.
7. **Perché il `refresh_token` del cliente emulato non sopravvive a un reload?** `AsmStatePersistenceService` lo cancella prima di persistere, per ridurre il rischio di account hijacking — feature-libs/asm/core/services/asm-state-persistence.service.ts:L74-L79.
8. **Quante richieste HTTP fa Customer 360 per una tab con tre sezioni?** Una: `AsmCustomer360Service` aggrega i `requestData` di tutti i componenti della tab in un'unica POST `customer360Queries` (l'overview è caricata a parte) — feature-libs/asm/customer-360/core/services/asm-customer-360.service.ts:L33-L73, feature-libs/asm/customer-360/components/asm-customer-360/asm-customer-360.component.ts:L116-L164.
9. **Come riceve i dati un componente di sezione C360 e perché è difficile scriverne uno custom?** L'host `cx-asm-customer-360-section` fornisce per istanza un `AsmCustomer360SectionContextSource` registrato anche come `AsmCustomer360SectionContext`; la sezione lo inietta. Ma `AsmCustomer360SectionContext` non è esportato dall'API pubblica — feature-libs/asm/customer-360/components/sections/asm-customer-360-section/asm-customer-360-section.component.ts:L23-L52, feature-libs/asm/customer-360/components/sections/index.ts:L7-L17.
10. **Perché le URL ASM non contengono `/occ/v2/<site>`?** L'adapter le costruisce con `{ baseSite: false, prefix: false }`; il base site passa come query param `baseSite` (search, liste, bind cart, create customer) oppure come segmento di path `${baseSiteId}` (`asmSessionEvent`, `asmCustomer360`). Gli endpoint di default iniziano con `/assistedservicewebservices/`, tranne `asmSessionEvent`, che è senza slash iniziale — feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L107-L121, feature-libs/asm/occ/adapters/occ-asm.adapter.ts:L78-L90, feature-libs/asm/occ/adapters/default-occ-asm-config.ts:L9-L22, feature-libs/asm/occ/adapters/default-occ-asm-config.ts:L17-L18, feature-libs/asm/customer-360/occ/adapters/default-occ-asm-customer-360-config.ts:L13-L14.

TAVOLA 29.1 **4.1 Bootstrap e attivazione della UI ASM**

Riferimenti allo SHA `5b7a1c2bf2808d7380bc20596d10f4fa710c3da1` (vedi 00-meta).

1. A cosa serve e perché esiste

Un prodotto *configurabile* è un prodotto il cui contenuto non è fissato a catalogo: il cliente sceglie valori di attributi (colore, potenza, accessori, quantità di componenti) e un motore di regole lato backend verifica la consistenza, calcola i prezzi e segnala conflitti. La libreria `@spartacus/product-configurator` porta questo flusso nello storefront: bottone "Configure" su PDP/PLP, pagina di configurazione interattiva a gruppi/tab, overview riepilogativa, add-to-cart della configurazione, modifica dal carrello e visualizzazione read-only da ordini, quote e saved cart.

Il codice deve risolvere quattro problemi che lo distinguono da quasi tutte le altre feature lib.

1. **Più motori di configurazione dietro la stessa UI.** Il repo supporta il *Variant Configurator* (VC, tipo `CPQCONFIGURATOR`), SAP CPQ cloud (tipo `CLOUDCPQCONFIGURATOR`) e un configuratore minimale *textfield* (tipo `TEXTFIELD`) — `feature-libs/product-configurator/common/core/model/common-configurator.model.ts:L60-L70`. VC e CPQ condividono store, facade e componenti ("rulebased"), e si distinguono solo nell'adapter scelto a runtime — `feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L160-L190`.
2. **Una configurazione appartiene a un "owner" che cambia nel tempo.** Prima dell'add-to-cart la configurazione è legata a un prodotto; dopo, a una entry di carrello; in un ordine, a una entry d'ordine. Il modello `CommonConfigurator.Owner` e la chiave `ownerType/ownerId` sono il filo conduttore di tutto — `feature-libs/product-configurator/common/core/model/common-configurator.model.ts:L11-L29`, `feature-libs/product-configurator/common/shared/utils/configurator-model-utils.ts:L19-L27`.
3. **Lo stato vive nell'URL.** Tipo di configuratore, owner e modalità (configurazione/overview, display-only, resolve issues, expert mode…) sono codificati in route e query param e riletti da un unico servizio, `ConfiguratorRouterExtractorService` — `feature-libs/product-configurator/common/components/service/configurator-router-extractor.service.ts:L28-L64`.
4. **Update incrementali e serializzati.** Ogni modifica di attributo invia al backend **un solo attributo cambiato**; gli update sono messi in coda con `concatMap` e il risultato finale è "consolidato" solo quando non ci sono più richieste pendenti — `feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L171-L207`, `:L403-L514`.

La libreria segue lo schema root (eager) / lazy delle feature lib (capitolo 12): un modulo root statico porta route, layout, nomi CMS che scatenano il lazy loading e un error handler HTTP; il resto (store NgRx, effects, adapter OCC, ~70 componenti) è caricato quando il CMS chiede uno dei componenti configuratore.

2. Mappa dei file

Tutti i path sono relativi a `feature-libs/product-configurator/` salvo dove indicato in forma completa.

PATH	RUOLO
`feature-libs/product-configurator/public_api.ts`	entry point principale vuoto (`export {}`)

`textfield/*`	entry `textfield`: root, core (store a singola configurazione), occ, 4 componenti
`projects/storefrontapp/src/app/spartacus/features/product-configurator/*.ts`	wiring nella demo app

File aggiuntivi

PATH	RUOLO
`feature-libs/product-configurator/_index.scss`	entry SCSS: importa gli stili di `common`, `rulebased`, `textfield`
`feature-libs/product-configurator/vitest.config.ts`	configurazione Vitest: forza `NX_TSCONFIG_PATH` su `tsconfig.spec.json`, alias helper di test, esclude `textfield/root/**` dalla coverage

3. Come funziona passo per passo

3.1 Packaging e wiring: entry point, root eager, feature lazy

L'entry principale non esporta nulla — `feature-libs/product-configurator/public_api.ts:L16-L19`. Gli entry point secondari sono `common`, `common/assets`, `rulebased`, `rulebased/root`, `rulebased/cpq`, `textfield`, `textfield/root`, mappati in `tsconfig.json:L181-L200` e `tsconfig.json:L223-L224`. Il `package.json` dichiara `221121.22.0` — `feature-libs/product-configurator/package.json:L2-L3` — che è lo stesso valore di `@spartacus/core` e `@spartacus/cart` allo SHA (`core-libs/core/package.json:L3-L3`, `feature-libs/cart/package.json:L3-L3`).

Nella demo app il wiring rulebased è in due pezzi:

- **statico**: `ProductConfiguratorRulebasedFeatureModule` importa `RulebasedConfiguratorRootModule` e, solo se `environment.cpq`, `CpqConfiguratorRootModule`; registra la feature lazy `productConfiguratorRulebased` che

punta a `RulebasedConfiguratorWrapperModule` — projects/storefrontapp/src/app/spartacus/features/product-configurator/product-configurator-rulebased-feature.module.ts:L22-L40;

- **lazy**: il wrapper importa `RulebasedConfiguratorModule` e, con `environment.cpq`, `RulebasedCpqConfiguratorModule` — projects/storefrontapp/src/app/spartacus/features/product-configurator/rulebased-configurator-wrapper.module.ts:L12-L21.

Il textfield è analogo: statico `TextfieldConfiguratorRootModule`, lazy `TextfieldConfiguratorModule` sotto `PRODUCT_CONFIGURATOR_TEXTFIELD_FEATURE` — projects/storefrontapp/src/app/spartacus/features/product-configurator/product-configurator-textfield-feature.module.ts:L21-L33. L'installazione via schematics passa per `addProductConfiguratorFeatures` — feature-libs/product-configurator/schematics/add-product-configurator/index.ts:L25-L44 (capitolo 43).

Root rulebased. `RulebasedConfiguratorRootModule` importa `CommonConfiguratorModule`, il root-feature module, i moduli di routing VC interattivo/overview, `RulebasedConfiguratorRoutingModule.forRoot()` e registra `ConfiguratorBadRequestHandler` come `HttpErrorHandler` multi — feature-libs/product-configurator/rulebased/root/rulebased-configurator-root.module.ts:L21-L37. Il nome feature è `'productConfiguratorRulebased'` — feature-libs/product-configurator/rulebased/root/feature-name.ts:L7-L8 — e i 18 tipi CMS che ne scatenano il caricamento (da `ConfiguratorForm` a `ConfiguratorOverviewSidebar`) sono in feature-libs/product-configurator/rulebased/root/rulebased-configurator-root-feature.module.ts:L11-L55. Il meccanismo `featureModules` + `cmsComponents` è descritto nel capitolo 12.

Root CPQ. `CpqConfiguratorRootModule` aggiunge i moduli route/layout CPQ e fornisce `routing.protected: true` ("force early login") come **default** config, tramite `provideDefaultConfig` — feature-libs/product-configurator/rulebased/root/cpq/cpq-configurator-root.module.ts:L16-L21. Conseguenza: salvo override con `provideConfig` dell'app, importarlo rende protetto l'intero storefront, non solo le pagine CPQ, eccetto le route configurate con `protected: false` esplicito — core-libs/core/src/routing/protected-routes/protected-routes.service.ts:L72-L81 (vedi §9).

Common. `CommonConfiguratorModule = CommonConfiguratorOccModule + CommonConfiguratorComponentsModule` — feature-libs/product-configurator/common/common-configurator.module.ts:L11-L14. È importato dai root module, quindi è eager: aggiunge gli endpoint prodotto `configurator` (`fields=code,configurable,configuratorType`) e `configuratorProductCard`, e inserisce lo scope `configurator` nello scope `list` dei prodotti — feature-libs/product-configurator/common/occ/default-occ-configurator-product-config.ts:L10-L30. Augmenta inoltre `Product` (`configurable`, `configuratorType`) e `OrderEntry` (`statusSummaryList`, `configurationInfos`) — feature-libs/product-configurator/common/core/model/augmented-core.model.ts:L8-L19 — e `Config` con `productConfigurator?: ProductConfiguratorConfig` — feature-libs/product-configurator/common/core/model/product-configurator.config.ts:L9-L15.

Lazy rulebased. `RulebasedConfiguratorModule = VariantConfiguratorOccModule + RulebasedConfiguratorCoreModule + RulebasedConfiguratorComponentsModule` — feature-libs/product-configurator/rulebased/rulebased-configurator.module.ts:L12-L19. Il core fornisce esplicitamente `RulebasedConfiguratorConnector` ("otherwise lazy loading does not work"), la config core di default e istanzia nel costruttore i listener di logout e cambio lingua — feature-libs/product-configurator/rulebased/core/rulebased-configurator-core.module.ts:L16-L34. Il CPQ lazy è `RulebasedCpqConfiguratorModule = CpqConfiguratorCommonModule + CpqConfiguratorOccModule` — feature-libs/product-configurator/rulebased/cpq/rulebased-cpq-configurator.module.ts:L14-L17.

3.2 Owner e tipi: il modello comune

`CommonConfigurator.Owner` ha `type`, `key` ("used as key in the configuration store"), `id` (codice prodotto, numero di entry, oppure documento+entry) e `configuratorType` ("Derived from the cxRoute") — feature-libs/

product-configurator/common/core/model/common-configurator.model.ts:L11-L29. `OwnerType` ammette `product`, `cartEntry`, `orderEntry`, `quoteEntry`, `savedCartEntry` — feature-libs/product-configurator/common/core/model/common-configurator.model.ts:L48-L54.

- La chiave è `ownerType + '/' + ownerId`, con errore se manca una delle parti — feature-libs/product-configurator/common/shared/utils/configurator-model-utils.ts:L19-L27; viene assegnata da `setOwnerKey` — feature-libs/product-configurator/common/shared/utils/common-configurator-utils.service.ts:L47-L49.
- L'owner "iniziale" ha `key`, `id` e `configuratorType` a `'INITIAL'` e `type = CommonConfigurator.OwnerType.PRODUCT` (`'product'`); `isInitialOwner` guarda solo `configuratorType` — feature-libs/product-configurator/common/shared/utils/configurator-model-utils.ts:L12-L48, in particolare :L33-L40.
- `createOwner` ha come default `ConfiguratorType.VARIANT` — feature-libs/product-configurator/common/shared/utils/configurator-model-utils.ts:L57-L68.
- Per entry di documenti (ordine, quote, saved cart) l'id è `documentId + '+' + entryNumber`; `decomposeOwnerId` lancia se le parti non sono esattamente 2 — feature-libs/product-configurator/common/shared/utils/common-configurator-utils.service.ts:L57-L75.
- `getCartId` usa il `guid` per l'utente anonimo, altrimenti `code` — feature-libs/product-configurator/common/shared/utils/common-configurator-utils.service.ts:L81-L88 (stessa regola del carrello, capitolo 25).
- VARIANT e TEXTFIELD sono "attribute based", CPQ è "bundle based" — feature-libs/product-configurator/common/shared/utils/common-configurator-utils.service.ts:L125-L146.

Il postfisso `_READ_ONLY` marca un tipo view-only (es. la route `configureCPQCONFIGURATOR_READ_ONLY`) — feature-libs/product-configurator/common/core/model/common-configurator.model.ts:L60-L70, feature-libs/product-configurator/rulebased/root/default-rulebased-routing-config.ts:L9-L28.

3.3 Route e `ConfiguratorRouterExtractorService`

Le route semantiche seguono la convenzione `configure<TYPE>` / `configureOverview<TYPE>`:

CXROUTE	PATH	DEFINITO IN
`configureCPQCONFIGURATOR`	`configure/vc/:ownerType/entityKey/:entityKey`	feature-libs/product-configurator/rulebased/root/default-rulebased-routing-config.ts:L9-L28
`configureOverviewCPQCONFIGURATOR`	`configure-overview/vc/…/displayOnly/:displayOnly` e senza `displayOnly`	idem
`configureCLOUDCPQCONFIGURATOR`	`configure/cpq/:ownerType/entityKey/:entityKey`	feature-libs/product-configurator/rulebased/root/cpq/default-cpq-interactive-routing-config.ts:L9-L17
`configureOverviewCLOUDCPQCONFIGURATOR`	`configure-overview/cpq/…` (due path)	feature-libs/product-configurator/rulebased/root/cpq/default-cpq-overview-routing-config.ts:L9-L20
`configureTEXTFIELD` / `configureOverviewTEXTFIELD`	`configure/textfield/:ownerType/entityKey/:entityKey` …	feature-libs/product-configurator/textfield/root/default-textfield-routing-config.ts:L9-L23

Le route Angular sono registrate con un trucco: `path: null` (con `@ts-ignore`), `data.cxRoute`, `PageLayoutComponent` e `CmsPageGuard` — feature-libs/product-configurator/rulebased/root/variant/variant-configurator-interactive.module.ts:L20-L38. Il path reale viene poi iniettato dal meccanismo

`RoutingConfig` di Spartacus a partire da `cxRoute` (capitolo 14); la pagina è una normale pagina CMS (capitolo 15).

`extractRouterData()` trasforma lo stato del router NgRx in un `ConfiguratorRouter.Data` — feature-libs/product-configurator/common/components/service/configurator-router-extractor.service.ts:L28-L64:

1. emette solo se esiste il parametro `entityKey`, e solo per stati senza `nextState` (navigazione completata) — :L28-L34;
2. i flag di query (`resolveIssues`, `skipConflicts`, `forceReload`, `expMode`, `displayRestartDialog`, `navigateToCheckout`, `isBundleOverview`) sono veri solo se uguali alla stringa `'true'` — :L38-L64;
3. `pageType` è `OVERVIEW` se il semanticRoute contiene `configureOverview`, altrimenti `CONFIGURATION` — :L38-L64, costanti in :L21-L22;
4. l'owner nasce da `ownerType`/`entityKey` (fallback: tipo `product` con `rootProduct`), il `configuratorType` è il suffisso del semanticRoute dopo `configureOverview` o `configure`, altrimenti `Error('Not able to determine configurator type')` — :L71-L113.

La forma completa di `ConfiguratorRouter.Data` è in feature-libs/product-configurator/common/components/service/configurator-router-data.ts:L8-L30. È questo il punto in cui **il tipo di configuratore entra nel sistema**: tutto ciò che segue (scelta dell'adapter, layout, comportamento CPQ vs VC) dipende da `owner.configuratorType` ricavato qui.

3.4 Gli ingressi: PDP/PLP e carrello

Bottone "Configure". `ConfigureProductModule` registra `ConfigureProductComponent` come componente CMS e lo inserisce anche nell'outlet `ProductListOutlets.ITEM_ACTIONS` in posizione AFTER — feature-libs/product-configurator/common/components/configure-product/configure-product.module.ts:L24-L42 (outlet: capitolo 17). Il componente legge il prodotto dal `ProductListItemContext` (PLP) oppure da `CurrentProductService` con scope DETAILS + `configurator` (PDP) — feature-libs/product-configurator/common/components/configure-product/configure-product.component.ts:L51-L62. È visibile solo se `product.configurable` e non è un base product read-only — feature-libs/product-configurator/common/components/configure-product/configure-product.component.html:L1-L2. Al click naviga a `cxRoute: 'configure' + product.configuratorType` con `ownerType: product`, `entityKey` = codice, e query `displayRestartDialog` e `productCode` — feature-libs/product-configurator/common/components/configure-product/configure-product.component.ts:L130-L148.

Componenti carrello. `CommonConfiguratorComponentsModule` importa i moduli carrello e fornisce la config UI comune — feature-libs/product-configurator/common/components/common-configurator-components.module.ts:L16-L26:

- `ConfiguratorCartEntryInfoComponent` in `CartOutlets.ITEM_DETAILS` (AFTER) — feature-libs/product-configurator/common/components/configurator-cart-entry-info/configurator-cart-entry-info.module.ts:L30-L36;
- `ConfiguratorIssuesNotificationComponent` **sostituisce** (REPLACE) `CartOutlets.ITEM_CONFIGURATOR_ISSUES` — feature-libs/product-configurator/common/components/configurator-issues-notification/configurator-issues-notification.module.ts:L28-L34; con il toggle `configuratorIssuesNotificationForConfigurableOnly` la notifica è nascosta per entry non configurabili — feature-libs/product-configurator/common/components/configurator-issues-notification/configurator-issues-notification.component.ts:L66-L76;
- `ConfiguratorCartEntryBundleInfoComponent` in `CartOutlets.ITEM_BUNDLE_DETAILS` (AFTER) — feature-libs/product-configurator/common/components/configurator-cart-entry-bundle-info/configurator-cart-entry-bundle-info.module.ts:L22-L28.

Il conteggio delle issue legge solo gli status summary `ERROR` — feature-libs/product-configurator/common/shared/utils/common-configurator-utils.service.ts:L106-L117. Le line item CPQ sono ricavate dai `configurationInfos` in formato legacy o versionato (`CI#@#VERSION` ≥ 2) — feature-libs/product-configurator/common/components/configurator-cart-entry-bundle-info/configurator-cart-entry-bundle-info.service.ts:L49-L76; i prodotti delle line item (per i link PDP) si caricano con lo scope `configuratorProductCard` solo dopo la prima espansione della lista — feature-libs/product-configurator/common/components/configurator-cart-entry-bundle-info/configurator-cart-entry-bundle-info.component.ts:L99-L143. Oltre `cartEntryBundleLineItemsThreshold` (default 10) e con toggle CPQ container, invece di espandere si naviga all'overview — feature-libs/product-configurator/common/components/configurator-cart-entry-bundle-info/configurator-cart-entry-bundle-info.component.ts:L225-L246, feature-libs/product-configurator/common/components/config/default-common-configurator-ui-settings.config.ts:L9-L14.

Link edit/display. `ConfigureCartEntryComponent` mappa il tipo di abstract order sull'owner type (ORDER→`orderEntry`, QUOTE→`quoteEntry`, SAVED_CART→`savedCartEntry`, default `cartEntry`) e, senza `AbstractOrderContext`, assume il carrello attivo — feature-libs/product-configurator/common/components/configure-cart-entry/configure-cart-entry.component.ts:L84-L88, :L145-L162. L'entityKey è il numero di entry per il carrello, altrimenti `documentId+entryNumber`; il route è `configureOverview<type>` se read-only e il tipo non è già `_READ_ONLY` — :L170-L193, :L331-L334. Le query params includono sempre `forceReload: true`, `resolveIssues`, `navigateToCheckout` (se si è in `checkoutReviewOrder`) e `productCode` — :L91-L103, :L336-L342.

3.5 Lo store NgRx rulebased

Feature key `productConfigurator`, entity type `[Configurator] Configuration Data`; lo stato è `configurations: EntityProcessesLoaderState<Configuration>` indicizzato per owner key — feature-libs/product-configurator/rulebased/core/state/configurator-state.ts:L10-L19. Lo state module registra `StoreModule.forFeature` (reducer via token) ed `EffectsModule.forFeature(ConfiguratorEffects)` con gli effect basic, cart e variant — feature-libs/product-configurator/rulebased/core/state/rulebased-configurator-state.module.ts:L19-L29, feature-libs/product-configurator/rulebased/core/state/effects/index.ts:L11-L15.

Il reducer è `StateUtils.entityProcessesLoaderReducer(CONFIGURATOR_DATA, configuratorReducer)` — feature-libs/product-configurator/rulebased/core/state/reducers/index.ts:L14-L24 — cioè un'entità con loader **e** contatore di processi (capitolo 19). Il reducer interno usa una `Map` lazy action-type → handler — feature-libs/product-configurator/rulebased/core/state/reducers/configurator.reducer.ts:L30-L45.

Punti chiave della semantica:

- `UpdateConfiguration` (e Add/Copy/RemoveContainerRow) sono `EntityProcessesIncrementAction` che impostano anche `meta.loader.load = true`; i Success/Fail sono `EntityProcessesDecrementAction` — feature-libs/product-configurator/rulebased/core/state/actions/configurator.action.ts:L161-L175, :L178-L209.
- `hasPendingChanges = processesCount > 0` sull'entità — feature-libs/product-configurator/rulebased/core/state/selectors/configurator.selector.ts:L44-L50, core-libs/core/src/state/utils/processes-loader/processes-loader.selectors.ts:L13-L17.
- `AddToCart` e `UpdateCartEntry` del configuratore incrementano invece i processi dell'entità **carrello** (`MULTI_CART_DATA`, cartId), decrementati da `CartAddEntrySuccess/Fail` e `CartUpdateEntrySuccess/Fail` della cart lib — feature-libs/product-configurator/rulebased/core/state/actions/configurator-cart.action.ts:L91-L105, feature-libs/cart/base/core/store/actions/cart-entry.action.ts:L38-L39. Così il carrello risulta "non stabile" durante l'add-to-cart di una configurazione.
- `takeOverChanges` fonde i gruppi nuovi con quelli già in store solo se il payload ne contiene, preserva `showConflictSolverDialog`, imposta `issueNavigationDone: true` e azzera i `priceSupplements` — feature-

libs/product-configurator/rulebased/core/state/reducers/configurator.reducer.ts:L436-L478.

- UPDATE_CONFIGURATION_FINALIZE_SUCCESS porta isCartEntryUpdateRequired = true, azzera overview e porta newConfiguration a false se definito — feature-libs/product-configurator/rulebased/core/state/reducers/configurator.reducer.ts:L122-L134; il dialog conflitti si apre se immediateConflictResolution && !consistent — :L136-L144.
- UPDATE_CART_ENTRY riporta isCartEntryUpdateRequired = false — :L175-L181.
- Il gruppo corrente iniziale è il primo di flatGroups, saltando i conflitti se immediateConflictResolution — :L406-L434.
- SET_NEXT_OWNER_CART_ENTRY imposta nextOwner = owner cartEntry con il numero di entry restituito dall'add-to-cart — :L290-L305.
- RemoveConfiguration è un EntityLoaderResetAction che accetta una chiave o un array — feature-libs/product-configurator/rulebased/core/state/actions/configurator.action.ts:L375-L380.

Action e selector sono esportati come namespace ConfiguratorActions e ConfiguratorSelectors — feature-libs/product-configurator/rulebased/core/state/actions/index.ts:L7-L8, feature-libs/product-configurator/rulebased/core/state/selectors/index.ts:L7-L8.

3.6 Il modello Configurator

Configurator.Configuration contiene configId, groups e flatGroups, prezzi, overview, owner/nextOwner, isCartEntryUpdateRequired, interactionState, pricingEnabled, immediateConflictResolution, newConfiguration, isPricingAsync — feature-libs/product-configurator/rulebased/core/model/configurator.model.ts:L135-L171. Lo stato puramente UI (gruppo corrente, parent del menu, gruppi visitati, modalità risoluzione conflitti, dialog) sta in InteractionState — :L177-L187 — **dentro** l'entità, non in uno slice separato: per questo va copiato quando l'owner cambia (§3.10).

GroupType distingue gruppi di attributi, sub-item, header conflitti, conflitti e righe container — :L295-L302. UiType elenca i tipi di attributo, inclusi quelli introdotti con CPQ (checkBoxListProduct, dropdownProduct, radioGroupProduct, container) — :L317-L343. UpdateType è Attribute / AttributeQuantity / ValueQuantity — :L364-L368. Costanti: ConflictIdPrefix, ConflictHeaderId, ContainerRowGroupIdPrefix, CustomUiTypeIndicator = '___', RetractValueCode — :L386-L390.

3.7 Facade

ConfiguratorCommonsService.getOrCreateConfiguration smista per owner type — feature-libs/product-configurator/rulebased/core/facade/configurator-commons.service.ts:L98-L119:

- cartEntry → ConfiguratorCartService.readConfigurationForCartEntry;
- orderEntry/quoteEntry/savedCartEntry → readConfigurationForOrderEntry;
- default (prodotto) → getOrCreateConfigurationForProduct, che dispatcha CreateConfiguration come side-effect (tap) se la configurazione non è "creata" e non è in loading né in errore, ed emette solo configurazioni create — :L457-L496. "Creata" significa configId non vuoto e flatGroups non vuoti, oppure un overview — feature-libs/product-configurator/rulebased/core/facade/utils/configurator-utils.service.ts:L120-L129.

updateConfiguration non fa nulla (solo warning in dev mode) se il carrello attivo ha un code e non è stabile; altrimenti dispatcha UpdateConfiguration con un **estratto** della configurazione — feature-libs/product-configurator/rulebased/core/facade/configurator-commons.service.ts:L127-L172. L'estratto contiene solo il percorso di gruppi fino al gruppo dell'attributo e l'unico attributo cambiato, e richiede changedAttribute.groupId — feature-libs/product-configurator/rulebased/core/facade/utils/configurator-utils.service.ts:L139-L201.

Altri metodi notevoli: `getConfigurationWithOverview` (dispatcha `GetConfigurationOverview` se manca) — feature-libs/product-configurator/rulebased/core/facade/configurator-commons.service.ts:L326-L356; `forceNewConfiguration` (`RemoveConfiguration` + `CreateConfiguration` con `forceReset: true`) — :L442-L455; `hasConflicts` (vero solo con `immediateConflictResolution === false` e primo gruppo CONFLICT_HEADER) — :L426-L436; `readAttributeDomain` (`attributeKey = attribute.key ?? attribute.name`) — :L519-L538.

`ConfiguratorCartService`:

- `readConfigurationForCartEntry` ritarda la lettura finché il carrello è stabile e il checkout non sta caricando, "this can lead to cache issues with promotions" — feature-libs/product-configurator/rulebased/core/facade/configurator-cart.service.ts:L41-L99;
- `readConfigurationForOrderEntry` scompone l'owner id e dispatcha `ReadOrderEntryConfiguration` (anche per quote e saved cart) — :L108-L153;
- `addToCart` usa `requireLoadedCart`, l'userId e quantità di default 1 — :L163-L190;
- `updateCartEntry` usa `configuration.owner.id` come numero di entry — :L199-L221.

`ConfiguratorGroupsService.navigateToGroup` marca visitato il gruppo corrente e dispatcha `ChangeGroup` — feature-libs/product-configurator/rulebased/core/facade/configurator-groups.service.ts:L281-L311; `navigateToContainerRow` attende i gruppi, trova la riga per `rowId` e naviga — :L126-L161; il gruppo conflitto da mostrare nel dialog è il primo `CONFLICT_GROUP` quando `showConflictSolverDialog` — :L231-L246. Il pattern facade/servizio è quello generale del capitolo 20, con una differenza: qui le facade sono classi concrete del core, non facade astratte con `facadeFactory` nel root.

3.8 Connector multi-adapter: come si sceglie VC o CPQ

`RulebasedConfiguratorConnector` **non** è `providedIn: 'root'` ("this would break lazy loading") e riceve gli adapter dal token statico multi `CONFIGURATOR_ADAPTER_LIST` — feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L18-L30. Ogni metodo sceglie l'adapter il cui `getConfiguratorType()` coincide con `owner.configuratorType`; se nessuno combacia lancia `No adapter found for configurator type: …` — :L160-L190. VC dichiara `ConfiguratorType.VARIANT`, CPQ `ConfiguratorType.CPQ` — feature-libs/product-configurator/rulebased/occ/variant/variant-configurator-occ.adapter.ts:L50-L52, feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.adapter.ts:L26-L28.

Il token riceve `VariantConfiguratorOccAdapter` da `VariantConfiguratorOccModule` (sempre, nel lazy rulebased) — feature-libs/product-configurator/rulebased/occ/variant/variant-configurator-occ.module.ts:L32-L85 — e `CpqConfiguratorOccAdapter` da `CpqConfiguratorOccModule` (solo se è caricato il modulo CPQ) — feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.module.ts:L20-L41.

Il contratto astratto è `RulebasedConfiguratorAdapter` (create/read/update, overview get/update, addToCart, read/update cart entry, read order entry, readPriceSummary, getConfiguratorType, searchVariants) — feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.adapter.ts:L12-L161. I metodi container row sono **opzionali**: se l'adapter non li implementa il connector restituisce `throwError("… is not supported for configurator type …")` — feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.adapter.ts:L58-L80, feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L63-L70, :L173-L183. `updateConfigurationOverview` del connector chiama l'update se c'è un `overview`, altrimenti il get — :L138-L150.

3.9 Adapter OCC Variant Configurator

`VariantConfiguratorOccModule` registra l'adapter e 8 converter multi (normalizer, serializer, prezzi, add-to-cart, update cart entry, overview) — feature-libs/product-configurator/rulebased/occ/variant/variant-configurator-occ.module.ts:L32-L85. Gli endpoint sono sotto `ccpconfigurator` — feature-libs/product-configurator/rulebased/occ/variant/default-occ-configurator-variant-config.ts:L9-L50.

OPERAZIONE	HTTP	RIFERIMENTO
create	GET con `expMode`, `forceReset` (+ `configIdTemplate`)	feature-libs/product-configurator/rulebased/occ/variant/variant-configurator-occ.adapter.ts:L67-L96
read	GET con `groupId`, `expMode`, `attributeKeyRequiresDomain`; forza `newConfiguration: false`	:L98-L127
update	PATCH del payload serializzato	:L129-L162
add to cart	POST, risposta via `CART_MODIFICATION_NORMALIZER`	:L164-L184
update cart entry	PUT	:L239-L241
read order/quote/saved cart entry	GET overview; configurazione con soli `overview` e gruppi vuoti	:L244-L305
price summary	GET `pricing` con `groupId = interactionState.currentGroup`	:L307-L331

Dopo la create, l'adapter attiva l'expert mode se `kbKey` è presente e riassegna l'owner — `:L67-L96`. Molte chiamate usano `HttpContext` con `OCC_HTTP_TOKEN.sendUserIdAsHeader: true` per l'emulazione ASM — `:L392-L406` (capitolo 29).

Il normalizer imposta `pricingEnabled ?? true`, `immediateConflictResolution ?? false`, `isPricingAsync: true` e mantiene `newConfiguration` tri-stato — feature-libs/product-configurator/rulebased/occ/variant/converters/occ-configurator-variant-normalizer.ts:L30-L47; il tipo UI è derivato troncando tutto ciò che segue `___` prima del mapping (UI type custom) — `:L440-L461`. Il serializer invia `configId`, `rootProduct`, `complete` e i gruppi — feature-libs/product-configurator/rulebased/occ/variant/converters/occ-configurator-variant-serializer.ts:L13-L32. Pattern adapter/converter: capitolo 21.

3.10 Adapter CPQ

Gli endpoint CPQ sono sotto `cpqconfigurator`, organizzati per tab, attributi, quantità valore, container rows e letture "Full" — feature-libs/product-configurator/rulebased/cpq/occ/default-occ-configurator-cpq-config.ts:L13-L45. L'adapter delega a `CpqConfiguratorOccService` e per l'update sceglie `updateValueQuantity` se `updateType === VALUE_QUANTITY`, altrimenti `updateAttribute` — feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.adapter.ts:L58-L71.

- Update: un PATCH per singolo attributo con `tabId` e, se presente, `rowId` — feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.service.ts:L315-L354. Il serializer prende il primo attributo seguendo il primo figlio lungo l'estratto — feature-libs/product-configurator/rulebased/cpq/rest/cpq-configurator-utils.ts:L67-L78; quantità valore di default 1 — feature-libs/product-configurator/rulebased/cpq/common/converters/cpq-configurator-value-serializer.ts:L30-L34.
- Container rows: POST `rows`, POST `copyRow`, DELETE — feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.service.ts:L356-L396. I tab annidati hanno groupId `CONTAINER_ROW@…@<tabId>` e solo il tabId finale va al backend — feature-libs/product-configurator/rulebased/cpq/rest/

cpq-configurator-utils.ts:L52-L56, feature-libs/product-configurator/rulebased/cpq/common/converters/cpq-configurator-normalizer.ts:L259-L261.

- Lettura entry documenti: ORDER_ENTRY, QUOTE_ENTRY, altrimenti saved cart — feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.service.ts:L414-L454.
- Non supportati: `readPriceSummary` restituisce la configurazione invariata ("so that UI does not run into exception"); `updateConfigurationOverview` e `searchVariants` lanciano errori **sincroni** — feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.adapter.ts:L106-L110, :L146-L160.

Il normalizer CPQ calcola `complete`/`consistent` dalle liste di messaggi, imposta `pricingEnabled: true` e trasforma ogni tab in un gruppo — feature-libs/product-configurator/rulebased/cpq/common/converters/cpq-configurator-normalizer.ts:L58-L95. Senza `hasFullConfigurationState`, solo il tab selezionato riceve gli attributi — :L1188-L1196; con il toggle `productConfiguratorCPQContainer` spento gli attributi container diventano `NOT_IMPLEMENTED` — :L670-L674, :L965-L975. L'add-to-cart serializza `{userId, cartId, product: {code}, quantity, configId}` — feature-libs/product-configurator/rulebased/cpq/occ/converters/occ-configurator-cpq-add-to-cart-serializer.ts:L24-L31.

3.11 Effects: create, update, cambio gruppo, errori

Create. `createConfiguration$` chiama il connector, dispatcha imperativamente `UpdatePriceSummary` (con il primo gruppo con attributi) ed emette `CreateConfigurationSuccess` + `SearchVariants` — feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L62-L105. `getFirstGroupWithAttributes` lancia se nessun gruppo ha attributi — feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic-effect.service.ts:L112-L125.

Update. `updateConfiguration$` usa `concatMap`: gli update sono processati uno dopo l'altro senza cancellare quelli in volo — feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L171-L207. Le container row hanno effect dedicati, sempre con `concatMap` — :L209-L238. `updateConfigurationSuccess$` agisce solo quando non ci sono più processi pendenti, ed emette `UpdateConfigurationFinalizeSuccess`, `UpdatePriceSummary`, `SearchVariants` e, se il gruppo applicabile differisce da quello del payload, `ChangeGroup` — :L403-L514. Dopo `ADD_CONTAINER_ROW_SUCCESS` si naviga nel primo tab della nuova riga — :L447-L459. `updatePriceSummary$` lavora solo con `pricingEnabled === true` — :L302-L313.

Errori. Un update fallito, a processi esauriti, produce `UpdateConfigurationFinalizeFail`, che `handleErrorOnUpdate$` converte in `ReadConfiguration` del primo gruppo con attributi: lo stato viene riallineato rileggendo dal backend — :L516-L585.

Cambio gruppo. `groupChange$` (switchMap) attende l'assenza di processi pendenti, legge il gruppo ed emette `SetCurrentGroup`, `SetMenuParentGroup`, `ReadConfigurationSuccess`, `UpdatePriceSummary` — :L587-L654. Per CPQ un tab già caricato è servito dallo store senza chiamata backend — :L693-L721, feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic-effect.service.ts:L34-L61.

Varianti. La ricerca varianti parte solo con `enableVariantSearch === true` e tipo VARIANT; altrimenti un secondo effect emette `SearchVariantsSuccess` vuoto per resettare il loading — feature-libs/product-configurator/rulebased/core/state/effects/configurator-variant.effect.ts:L25-L82.

Pulizia. `removeProductBoundConfigurations$` rimuove le entità la cui chiave contiene `product` — feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L656-L681; `removeCartBoundConfigurations$` quelle `cartEntry` e quelle `product` con `nextOwner` — feature-libs/product-configurator/rulebased/core/state/effects/configurator-cart.effect.ts:L210-L248.

3.12 Add to cart, cambio di owner e overview

`ConfiguratorAddToCartButtonComponent.onAddToCart` marca visitato il gruppo corrente, attende che non ci siano processi pendenti e poi aggiorna l'entry (owner `cartEntry`) o aggiunge al carrello (owner `product`) — feature-libs/product-configurator/rulebased/components/add-to-cart-button/configurator-add-to-cart-button.component.ts:L348-L393.

Per un owner prodotto:

1. disabilita il bottone e chiama `ConfiguratorCartService.addToCart` — :L395-L413;
2. `addToCart$` chiama l'adapter ed emette `AddNextOwner` (con l'entryNumber) e `CartAddEntrySuccess`; senza `entryNumber` lancia `Entry number is required in addToCart response`, catturato come `CartAddEntryFail` — feature-libs/product-configurator/rulebased/core/state/effects/configurator-cart.effect.ts:L34-L94;
3. `addOwner$` emette `SetNextOwnerCartEntry` e `SetInteractionState`, che copia l'`interactionState` della configurazione prodotto sull'entità con la nuova chiave `cartEntry/<n>` — :L250-L285;
4. il componente attende `nextOwner !== undefined` e naviga; sulla pagina di configurazione rimuove l'eventuale configurazione cartEntry preesistente con lo stesso numero, mentre la product-bound resta fino all'uscita dalle route `configure*` — feature-libs/product-configurator/rulebased/components/add-to-cart-button/configurator-add-to-cart-button.component.ts:L395-L461;
5. dalla pagina di configurazione la navigazione passa prima per `configure<type>` con owner `cartEntry` e `replaceUrl: true` (così il tasto back torna alla configurazione), poi a `configureOverview<type>` — :L172-L202, commento in :L177-L180; dall'overview si va direttamente al carrello — :L261-L281.

Per un owner cartEntry l'update del carrello avviene solo se `isCartEntryUpdateRequired` — :L463-L482. `updateCartEntry$` emette `CartUpdateEntrySuccess` e solo dopo `RemoveConfiguration`, perché il backend CPQ può aver scartato la bozza — feature-libs/product-configurator/rulebased/core/state/effects/configurator-cart.effect.ts:L96-L139. La lettura della configurazione della entry emette success + `UpdatePriceSummary` + `SearchVariants` — :L141-L180.

In display-only l'uscita dall'overview porta a dettaglio ordine, dettaglio quote, quote del saved cart, carrello, PDP o review checkout a seconda dell'owner — feature-libs/product-configurator/rulebased/components/add-to-cart-button/configurator-add-to-cart-button.component.ts:L484-L518.

3.13 Listener e servizi con stato

- `ConfiguratorRouterListener` (istanziato da `ConfiguratorRouterModule`) rimuove le configurazioni legate al carrello e riporta la quantità a 1 quando il semanticRoute non contiene `configure` — feature-libs/product-configurator/rulebased/core/facade/routing/configurator-router.listener.ts:L25-L38, feature-libs/product-configurator/rulebased/core/facade/routing/configurator-router.module.ts:L10-L15.
- Al `LogoutEvent` si azzerano expert mode e configurazioni product-bound — feature-libs/product-configurator/rulebased/core/events/configurator-logout-event.listener.ts:L27-L35; al `LanguageSetEvent` si rimuovono le product-bound — feature-libs/product-configurator/rulebased/core/events/configurator-language-set-event.listener.ts:L25-L31.
- `ConfiguratorExpertModeService` tiene due `ReplaySubject(1)` ed è documentato come OCC-specifico e sostituibile — feature-libs/product-configurator/rulebased/core/services/configurator-expert-mode.service.ts:L10-L22; `ConfiguratorQuantityService` è un `BehaviorSubject<number>(1)` — feature-libs/product-configurator/rulebased/core/services/configurator-quantity.service.ts:L16-L35.

3.14 La pagina: form, gruppo e composizione dinamica degli attributi

`ConfiguratorFormComponent` (CMS `ConfiguratorForm`) ottiene la configurazione con `getOrCreateConfiguration(owner, configIdTemplate)` solo sulle pagine CONFIGURATION — feature-libs/product-configurator/rulebased/components/form/configurator-form.component.ts:L58-L70. In `ngOnInit` controlla il dialog conflitti, apre il restart dialog se richiesto e la configurazione non è nuova, gestisce `resolveIssues`, `rowId` (con toggle CPQ container) ed `expMode` — :L113-L192.

`ConfiguratorGroupComponent` calcola per ogni attributo la chiave `AttributeType_` + `uiTypeVariation` (se contiene ___) oppure + `uiType` — feature-libs/product-configurator/rulebased/components/group/configurator-group.component.ts:L121-L127. Il template rende per ogni attributo tre slot con la direttiva `cxConfiguratorAttributeComponent`: `Header`, il tipo, `Footer` — feature-libs/product-configurator/rulebased/components/group/configurator-group.component.html:L25-L59.

La direttiva è un piccolo "CMS mapping" interno:

1. legge la mappa `productConfigurator.assignment` da `ConfiguratorAttributeCompositionConfig` (`useExisting: Config`) — feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.config.ts:L10-L24, feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.directive.ts:L37-L39;
2. in `ngOnChanges` ricrea il componente solo se l'attributo cambia (deep equal) o cambia il gruppo — :L59-L72;
3. crea il componente con `vcr.createComponent` e un injector figlio che fornisce `ConfiguratorAttributeCompositionContext` (useValue); se manca l'assignment, warning in dev mode — :L74-L101.

Il contesto contiene componentKey, attribute, owner, group, language, expMode, flag di navigazione e `isPricingAsync` — feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.model.ts:L11-L21. Ogni modulo di tipo registra il proprio componente con `provideDefaultConfig({productConfigurator:{assignment:{…}}})` — feature-libs/product-configurator/rulebased/components/attribute/types/radio-button/configurator-attribute-radio-button.module.ts:L33-L43; Header e Footer usano le chiavi `Header`/`Footer` — feature-libs/product-configurator/rulebased/components/attribute/header/configurator-attribute-header.module.ts:L35-L35, feature-libs/product-configurator/rulebased/components/attribute/footer/configurator-attribute-footer.module.ts:L27-L27.

Gerarchia delle classi base: `ConfiguratorAttributeBaseComponent` (senza decorator, usa `inject`) → `ConfiguratorAttributeSelectionBaseComponent` (`@Directive()` astratta, `loading$`) → single/multi selection base — feature-libs/product-configurator/rulebased/components/attribute/types/base/configurator-attribute-base.component.ts:L20-L37, feature-libs/product-configurator/rulebased/components/attribute/types/base/configurator-attribute-selection-base.component.ts:L23-L28. `loading$` torna a false quando il loading della configurazione finisce, perché con CPQ API V2 un round-trip può non cambiare l'attributo e il componente non verrebbe ricreato — :L42-L56. La single selection chiama `updateConfiguration` con `selectedSingleValue` e `UpdateType.ATTRIBUTE` — feature-libs/product-configurator/rulebased/components/attribute/types/base/configurator-attribute-single-selection-base.component.ts:L92-L130. Chi usa `ConfiguratorAttributePriceChangeService` deve fornirlo a livello di componente — feature-libs/product-configurator/rulebased/components/attribute/types/base/configurator-attribute-base.component.ts:L24-L34, feature-libs/product-configurator/rulebased/components/attribute/types/radio-button/configurator-attribute-radio-button.component.ts:L29-L33.

`RulebasedConfiguratorComponentsModule` aggrega 24 moduli (price summary, add-to-cart, menu, form, overview, conflitti, restart dialog…) — feature-libs/product-configurator/rulebased/components/rulebased-

configurator-components.module.ts:L32-L60.

3.15 Layout e page layout handler

Il layout interattivo VC (VariantConfigurationTemplate) ha header con VariantConfigExitButton, navigation VariantConfigMenu (vuota su lg) e slot di contenuto dedicati — feature-libs/product-configurator/rulebased/root/variant/variant-configurator-interactive-layout.module.ts:L16-L66. L'overview VC aggiunge la sezione non standard headerDisplayOnly e registra VariantConfiguratorPageLayoutHandler come PAGE_LAYOUT_HANDLER multi — feature-libs/product-configurator/rulebased/root/variant/variant-configurator-overview-layout.module.ts:L22-L66. L'handler, se routerData.displayOnly, sostituisce gli slot dell'header con quelli di headerDisplayOnly (lg o xs via BreakpointService.isUp) — feature-libs/product-configurator/rulebased/root/variant/variant-configurator-page-layout-handler.ts:L32-L71.

CPQ usa un unico CpqConfigurationTemplate per pagina interattiva e overview, con sezioni extra headerDisplayOnly e navigationDisplayOnly — feature-libs/product-configurator/rulebased/root/cpq/cpq-configurator-layout.module.ts:L18-L92; CpqConfiguratorPageLayoutHandler antepone PreHeader sulla pagina di configurazione, usa gli slot display-only sull'overview read-only e toglie CpqConfigOverviewNavigation col toggle CPQ container spento — feature-libs/product-configurator/rulebased/root/cpq/cpq-configurator-page-layout-handler.ts:L97-L160. PAGE_LAYOUT_HANDLER e LayoutConfig sono trattati nel capitolo 18.

3.16 Conflitti e dialog

LAUNCH_CALLER dello storefront è aumentato con CONFLICT_SOLVER, CONFIGURATOR_OV_FILTER, CONFIGURATOR_RESTART_DIALOG, assegnando i valori anche a runtime — feature-libs/product-configurator/rulebased/components/config/augmented-config.model.ts:L14-L33. Il conflict solver è un dialog inlineRoot — feature-libs/product-configurator/rulebased/components/conflict-solver-dialog/default-configurator-conflict-solver-layout.config.ts:L10-L18 — lanciato da ConfiguratorConflictSolverDialogLauncherService (istanziato dal costruttore del modulo, feature-libs/product-configurator/rulebased/components/conflict-solver-dialog/configurator-conflict-solver-dialog.module.ts:L35-L41), che apre il dialog quando c'è un gruppo conflitto, ignora riemissioni con stesso gruppo e stesso navigationId, e lo chiude con CLOSE_NO_CONFLICTS_EXIST — feature-libs/product-configurator/rulebased/components/conflict-solver-dialog/configurator-conflict-solver-dialog-launcher.service.ts:L66-L92.

3.17 Error handler HTTP

ConfiguratorBadRequestHandler (400, priorità NORMAL) intercetta solo IllegalStateError con messaggio "base product is defined as 'make-to-stock'" e mostra configurator.httpHandlers.makeToStockBaseProductIssue — feature-libs/product-configurator/rulebased/root/http-interceptors/configurator-bad-request.handler.ts:L22-L82. Con il toggle productConfiguratorCPQContainer fa match anche sui 400 UnknownIdentifierError delle richieste product card, ma in quel caso handleError non aggiunge messaggi: il 400 viene "inghiottito" — :L84-L125, :L42-L48. Il meccanismo HttpErrorHandler è nel capitolo 41.

3.18 Textfield: un configuratore "template"

Il textfield è descritto come configuratore minimale (3 attributi senza dipendenze) che "serves as a template for other configurator implementations" — feature-libs/product-configurator/textfield/textfield-configurator.module.ts:L12-L23. Differenze rispetto al rulebased:

- root con CMS `TextfieldConfigurationForm`, due route `path: null` e template a slot unico — feature-libs/product-configurator/textfield/root/textfield-configurator-root.module.ts:L19-L57, feature-libs/product-configurator/textfield/root/textfield-configurator-root-feature.module.ts:L11-L11; feature `productConfiguratorTextfield` — feature-libs/product-configurator/textfield/root/feature-name.ts:L7-L8;
- connector a singolo adapter (classe astratta `ConfiguratorTextfieldAdapter`), fornito esplicitamente dal core — feature-libs/product-configurator/textfield/core/textfield-configurator-core.module.ts:L15-L19, feature-libs/product-configurator/textfield/core/connectors/configurator-textfield.connector.ts:L14-L16;
- store `productConfigurationTextfield` con un singolo `LoaderState` (una configurazione alla volta) — feature-libs/product-configurator/textfield/core/state/configuration-textfield-state.ts:L10-L20, feature-libs/product-configurator/textfield/core/state/reducers/index.ts:L17-L25;
- update **solo locale**: nessun effect chiama il backend per `UPDATE_CONFIGURATION` — feature-libs/product-configurator/textfield/core/facade/configurator-textfield.service.ts:L81-L101, :L253-L271;
- dopo add-to-cart/update entry, `RemoveConfiguration` + `CartActions.LoadCart` (ricarica intera del carrello) — feature-libs/product-configurator/textfield/core/state/effects/configurator-textfield.effect.ts:L55-L84 (add-to-cart), :L86-L120 (update entry);
- endpoint `configurator/textfield`, update entry via POST — feature-libs/product-configurator/textfield/occ/default-occ-configurator-textfield-config.ts:L13-L28, feature-libs/product-configurator/textfield/occ/occ-configurator-textfield.adapter.ts:L154-L156.

3.19 Stili e traduzioni

Le traduzioni sono nel chunk `configurator`, esportate come `configuratorTranslationsXx` — feature-libs/product-configurator/common/assets/translations/translations.ts:L9-L15 (capitolo 37). Ogni `_index.scss` applica `@extend %<selector>` su una lista `!default` di selettori e su `cx-page-layout.<Template>` per i template — feature-libs/product-configurator/rulebased/_index.scss:L38-L59 (capitolo 38).

---

5. Estratti di codice reale

5.1 Selezione dell'adapter

feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L18-L30

```ts
//Not provided in root, as this would break lazy loading
@Injectable()
export class RulebasedConfiguratorConnector {
  static CONFIGURATOR_ADAPTER_LIST = new InjectionToken<
    RulebasedConfiguratorAdapter[]
  >('ConfiguratorAdapterList');

  constructor(
    @Inject(RulebasedConfiguratorConnector.CONFIGURATOR_ADAPTER_LIST)
    protected adapters: RulebasedConfiguratorAdapter[],
    protected configUtilsService: CommonConfiguratorUtilsService,
    protected config: ConfiguratorCoreConfig
  ) {}
```

feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L160-L190

```ts
  protected getAdapter(configuratorType: string): RulebasedConfiguratorAdapter {
    const adapterResult = this.adapters.find((adapter) =>
      this.isAdapterMatching(adapter, configuratorType)
    );
    if (adapterResult) {
      return adapterResult;
    } else {
      throw new Error(
        'No adapter found for configurator type: ' + configuratorType
      );
    }
  }
  // ...
  protected isAdapterMatching(
    adapter: RulebasedConfiguratorAdapter,
    configuratorType: string
```

```
  ): boolean {
    return adapter.getConfiguratorType() === configuratorType;
  }
```

5.2 Registrazione dell'adapter CPQ nel token multi

feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.module.ts:L20-L41

```ts
@NgModule({
  imports: [CommonModule],
  providers: [
    provideDefaultConfigFactory(defaultOccCpqConfiguratorConfigFactory),
    // ...
    {
      provide: RulebasedConfiguratorConnector.CONFIGURATOR_ADAPTER_LIST,
      useClass: CpqConfiguratorOccAdapter,
      multi: true,
    },
  ],
})
export class CpqConfiguratorOccModule {}
```

5.3 Owner e tipo dal router

feature-libs/product-configurator/common/components/service/configurator-router-extractor.service.ts:L71-L113

```ts
  createOwnerFromRouterState(
    routerState: RouterState
  ): CommonConfigurator.Owner {
    const owner: CommonConfigurator.Owner =
      ConfiguratorModelUtils.createInitialOwner();
    const params = routerState.state.params;
    if (params.ownerType) {
      const entityKey = params.entityKey;
      owner.type = params.ownerType;

      owner.id = entityKey;
    } else {
      owner.type = CommonConfigurator.OwnerType.PRODUCT;
      owner.id = params.rootProduct;
    }
    const semanticRoute = routerState.state.semanticRoute;
    if (semanticRoute) {
      const configuratorType =
        this.getConfiguratorTypeFromSemanticRoute(semanticRoute);
      owner.configuratorType = configuratorType;
```

```
  }
  this.configUtilsService.setOwnerKey(owner);
  return owner;
}
// ...
protected getConfiguratorTypeFromSemanticRoute(
  semanticRoute: string
): string {
  if (semanticRoute.startsWith(this.ROUTE_FRAGMENT_OVERVIEW)) {
    return semanticRoute.split(this.ROUTE_FRAGMENT_OVERVIEW)[1];
  } else if (semanticRoute.startsWith(this.ROUTE_FRAGMENT_CONFIGURE)) {
    return semanticRoute.split(this.ROUTE_FRAGMENT_CONFIGURE)[1];
  } else {
    throw new Error('Not able to determine configurator type');
  }
}
```

5.4 Create "lazy" dalla facade

feature-libs/product-configurator/rulebased/core/facade/configurator-commons.service.ts:L457-L496

```ts
protected getOrCreateConfigurationForProduct(
  owner: CommonConfigurator.Owner,
  configIdTemplate?: string
): Observable<Configurator.Configuration> {
  return this.store.pipe(
    select(
      ConfiguratorSelectors.getConfigurationProcessLoaderStateFactory(
        owner.key
      )
    ),
    tap((configurationState) => {
      if (
        (configurationState.value === undefined ||
          !this.configuratorUtils.isConfigurationCreated(
            configurationState.value
          )) &&
        configurationState.loading !== true &&
        configurationState.error !== true
      ) {
        this.store.dispatch(
          new ConfiguratorActions.CreateConfiguration({
            owner,
            configIdTemplate,
          })
        );
      }
    }),
```

```
    filter(
      (configurationState) =>
        configurationState.value !== undefined &&
        this.configuratorUtils.isConfigurationCreated(
          configurationState.value
        )
    ),
    // ...
```

5.5 Update serializzati con `concatMap`

feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L171-L207

```ts
updateConfiguration$: Observable<
  | ConfiguratorActions.UpdateConfigurationSuccess
  | ConfiguratorActions.UpdateConfigurationFail
> = createEffect(() =>
  this.actions$.pipe(
    ofType(ConfiguratorActions.UPDATE_CONFIGURATION),
    map((action: ConfiguratorActions.UpdateConfiguration) => action.payload),
    //concatMap (not mergeMap) so that updates are processed strictly one after
    //another: concatMap queues the updates without cancelling in-flight
    //emissions (switchMap would cancel and lose changes; each update only sends
    //one changed attribute at a time).
    concatMap((payload: Configurator.Configuration) => {
      return this.configuratorCommonsConnector
        .updateConfiguration(payload)
        .pipe(
          map((configuration: Configurator.Configuration) => {
            return new ConfiguratorActions.UpdateConfigurationSuccess({
              ...configuration,
              interactionState: {
                isConflictResolutionMode:
                  payload.interactionState.isConflictResolutionMode,
              },
            });
          }),
          catchError((error) => {
            const errorPayload = tryNormalizeHttpError(error, this.logger);
            return [
              new ConfiguratorActions.UpdateConfigurationFail({
                configuration: payload,
                error: errorPayload,
              }),
            ];
          })
        );
```

```
      })
    )
  );
```

5.6 Reducer di finalize

feature-libs/product-configurator/rulebased/core/state/reducers/configurator.reducer.ts:L122-L144

```ts
function handleActionUpdateConfigurationFinalizeSuccess(
  state: Configurator.Configuration,
  action: ConfiguratorActions.UpdateConfigurationFinalizeSuccess
): Configurator.Configuration | undefined {
  const result: Configurator.Configuration = takeOverChanges(action, state);
  checkConflictSolverDialog(result);
  result.isCartEntryUpdateRequired = true;
  result.overview = undefined;
  if (state.interactionState.newConfiguration !== undefined) {
    result.interactionState.newConfiguration = false;
  }
  return result;
}

function checkConflictSolverDialog(
  configuration: Configurator.Configuration
): void {
  configuration.interactionState.showConflictSolverDialog =
    configuration.immediateConflictResolution && !configuration.consistent;
  if (configuration.interactionState.showConflictSolverDialog) {
    configuration.interactionState.issueNavigationDone = true;
  }
}
```

5.7 Update cart entry e rimozione della bozza

feature-libs/product-configurator/rulebased/core/state/effects/configurator-cart.effect.ts:L109-L124

```ts
              switchMap((cartModification: CartModification) => {
                return [
                  new CartActions.CartUpdateEntrySuccess({
                    userId: payload.userId,
                    cartId: payload.cartId,
                    entryNumber: payload.cartEntryNumber,
                    quantity: cartModification.quantity,
                  }),
                  // The backend might have discarded the draft configuration (CPQ), so it needs
                  // to be re-read from the cart entry. Must not happen before the update has
```

```
                // succeeded, as pending configuration success actions would re-create it.
                new ConfiguratorActions.RemoveConfiguration({
                  ownerKey: payload.configuration.owner.key,
                }),
              ];
            }),
```

5.8 Composizione dinamica degli attributi

feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.directive.ts:L59-L101

```ts
  ngOnChanges(): void {
    const attributeChanged = !ObjectComparisonUtils.deepEqualObjects(
      this.lastRenderedAttribute,
      this.context.attribute
    );
    const groupChanged = this.lastRenderedGroupId !== this.context.group.id;
    // attribute can occur with same content twice in different groups
    // for example this happens for conflicts. An attribute is rendered differently (link from/to
conflict) based on
    // if it is part of conflict group or of ordinary group
    if (attributeChanged || groupChanged) {
      const key = this.context.componentKey;
      this.renderComponent(this.attrComponentAssignment[key], key);
    }
  }

  protected renderComponent(component: any, componentKey: string) {
    if (component) {
      this.lastRenderedAttribute = this.context.attribute;
      this.lastRenderedGroupId = this.context.group.id;
      this.vcr.clear();
      this.vcr.createComponent(component, {
        injector: this.getComponentInjector(),
      });
    } else {
      if (isDevMode()) {
        this.logger.warn(
          'No attribute type component available for: ' + componentKey
        );
      }
    }
  }
  // ...
```

feature-libs/product-configurator/rulebased/components/attribute/types/radio-button/configurator-attribute-radio-button.module.ts:L33-L43

```ts
providers: [
  provideDefaultConfig({
    productConfigurator: {
      assignment: {
        AttributeType_radioGroup: ConfiguratorAttributeRadioButtonComponent,
        AttributeType_radioGroup_add:
          ConfiguratorAttributeRadioButtonComponent,
      },
    },
  }),
],
```

5.9 Navigazione verso l'overview con history riscritta

feature-libs/product-configurator/rulebased/components/add-to-cart-button/configurator-add-to-cart-button.component.ts:L172-L202

```ts
protected navigateToOverview(
  configuratorType: string,
  owner: CommonConfigurator.Owner,
  productCode?: string
): void {
  // When navigating to the overview page, we change the browser history,
  // by changing the owner type and entity key (cart entry) in the configure URL.
  // With that the user can return to the configuration page
  // by using the browser back button.
  this.routingService
    .go(
      {
        cxRoute: 'configure' + configuratorType,
        params: { ownerType: 'cartEntry', entityKey: owner.id },
      },
      { replaceUrl: true }
    )
    .then(() => {
      this.routingService
        .go(
          {
            cxRoute: 'configureOverview' + configuratorType,
            params: { ownerType: 'cartEntry', entityKey: owner.id },
          },
          { queryParams: { productCode: productCode } }
        )
        // ...
```

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
toggle `configuratorIssuesNotificationForConfigurableOnly`	boolean	`false`	`core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L862-L862`, `:L1107-L1107`	`feature-libs/product-configurator/common/components/configurator-issues-notification/configurator-issues-notification.component.ts:L66-L76`
toggle `productConfiguratorConsolidatedButtonDisabling`	boolean	`false` (`core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1097-L1097`)	`core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L721-L721`	`feature-libs/product-configurator/rulebased/components/attribute/types/multi-selection-bundle/configurator-attribute-multi-selection-bundle.component.html:L19-L19`

Le abstract class di config sono `ConfiguratorCoreConfig` (`feature-libs/product-configurator/rulebased/core/config/configurator-core.config.ts:L10-L20`), `ConfiguratorUISettingsConfig` (`feature-libs/product-configurator/rulebased/components/config/configurator-ui-settings.config.ts:L10-L57`), e `CommonConfiguratorUISettingsConfig`: queste sono `providedIn: 'root'` con `useExisting: Config` (capitolo 11). `ConfiguratorMessageConfig` invece è una abstract class senza decorator — `feature-libs/product-configurator/rulebased/components/config/configurator-message.config.ts:L13-L15` — fornita solo da `ConfiguratorUpdateMessageModule` con un provider `{ provide: ConfiguratorMessageConfig, useExisting: Config }` — `feature-libs/product-configurator/rulebased/components/update-message/configurator-update-message.module.ts:L30-L31`; iniettarla fuori dall'injector che importa quel modulo non trova provider.

---

7. Commenti e note notevoli dal sorgente

- "Not provided in root, as this would break lazy loading" — `feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L18-L18`.
- "Explicit providing of connector because otherwise lazy loading does not work" — `feature-libs/product-configurator/rulebased/core/rulebased-configurator-core.module.ts:L16-L19`; idem nel text-field — `feature-libs/product-configurator/textfield/core/textfield-configurator-core.module.ts:L11-L14`.
- "// TODO: Inline this factory when we start releasing Ivy compiled libraries" — `feature-libs/product-configurator/rulebased/root/rulebased-configurator-root-feature.module.ts:L32-L32`, `feature-libs/product-configurator/textfield/root/textfield-configurator-root-feature.module.ts:L13-L13`.
- "We can neither omit the path nor set to undefined" + `@ts-ignore` su `path: null` — `feature-libs/product-configurator/rulebased/root/variant/variant-configurator-interactive.module.ts:L24-L26`.
- "//force early login" — `feature-libs/product-configurator/rulebased/root/cpq/cpq-configurator-root.module.ts:L18-L18`.
- `@ts-ignore TODO (#12620)` sul reducer entity — `feature-libs/product-configurator/rulebased/core/state/reducers/index.ts:L16-L20`.
- "TODO: remove the logic below when configurable products support "Saved Cart" and "Save For Later"" — `feature-libs/product-configurator/common/components/configurator-cart-entry-info/configurator-cart-entry-info.component.ts:L41-L41`, `feature-libs/product-configurator/common/components/configurator-issues-notification/configurator-issues-notification.component.ts:L56-L56`.
- "Requires default change detection strategy, as the disabled state of the quantity form control may change" — `feature-libs/product-configurator/common/components/configurator-cart-entry-info/configurator-cart-entry-info.component.ts:L16-L25`.

- Il commento su `concatMap` vs `switchMap` degli update — `feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L178-L181`.
- "we need a trinary state true, false, undefined!" — `feature-libs/product-configurator/rulebased/occ/variant/converters/occ-configurator-variant-normalizer.ts:L45-L45`.
- Il commento sul cleanup posticipato della configurazione product-bound ("existing observables would instantly trigger a re-create") — `feature-libs/product-configurator/rulebased/components/add-to-cart-button/configurator-add-to-cart-button.component.ts:L448-L458`.
- "We don't need this method but cannot remove it due to backward compatibility" (`ngOnInit` della direttiva) — `feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.directive.ts:L46-L52`.
- JSDoc di `ConfiguratorExpertModeService`: "This implementation is OCC specific" — `feature-libs/product-configurator/rulebased/core/services/configurator-expert-mode.service.ts:L10-L14`.
- JSDoc del toggle `productConfiguratorCPQContainer` con l'elenco delle classi coinvolte — `core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L760-L788`.
- JSDoc di `getCpqContainerFragment` sulle assunzioni `anchorScrolling: 'enabled'` e assenza di id uguali al rowId — `feature-libs/product-configurator/common/components/configure-cart-entry/configure-cart-entry.component.ts:L195-L216`.
- Il JSDoc del normalizer textfield dice "Converts addToCart parameters into the generic format" ma converte una configurazione — `feature-libs/product-configurator/textfield/occ/converters/occ-configurator-textfield-normalizer.ts:L23-L28`.

8. Extension point

EXTENSION POINT	COME SI USA	RIFERIMENTO	RICETTA
`RulebasedConfiguratorConnector.CONFIGURATOR_ADAPTER_LIST`	aggiungere un adapter `multi: true` per un nuovo `configuratorType` (o sostituirne uno)	`feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L21-L23`	52 — OCC, adapter, converter
`RulebasedConfiguratorAdapter`	classe astratta da implementare; container row opzionali	`feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.adapter.ts:L12-L161`	52
Token converter VC (`VARIANT_CONFIGURATOR_NORMALIZER`, `VARIANT_CONFIGURATOR_SERIALIZER`, …) e CPQ (`CPQ_CONFIGURATOR_NORMALIZER`, …)	aggiungere normalizer/serializer `multi: true` per campi custom	`feature-libs/product-configurator/rulebased/occ/variant/variant-configurator-occ.converters.ts:L12-L49`, `feature-libs/product-configurator/rulebased/cpq/common/converters/cpq-configurator.converters.ts:L12-L26`	52
Endpoint `backend.occ.endpoints.*`	override di URL/fields via `provideConfig`	§6	52
`productConfigurator.assignment`	mappare un `AttributeType_<uiType>` (anche custom con `___`) su un componente proprio	`feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.config.ts:L10-L24`	51 — componenti CMS, outlet, layout

EXTENSION POINT	COME SI USA	RIFERIMENTO	RICETTA
`ConfiguratorAttributeCompositionContext` + classi base	il componente custom inietta il contesto ed estende `ConfiguratorAttributeSingleSelectionBaseComponent` ecc.	`feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.model.ts:L11-L21`, `feature-libs/product-configurator/rulebased/components/attribute/types/base/configurator-attribute-selection-base.component.ts:L23-L28`	51
`cmsComponents` (18 nomi rulebased, `TextfieldConfigurationForm`, `ConfigureProductComponent`)	sostituire un componente di pagina	`feature-libs/product-configurator/rulebased/root/rulebased-configurator-root-feature.module.ts:L11-L55`	51
Outlet `ProductListOutlets.ITEM_ACTIONS`, `CartOutlets.ITEM_DETAILS`, `ITEM_CONFIGURATOR_ISSUES`, `ITEM_BUNDLE_DETAILS`	aggiungere/sostituire contenuti nel carrello e nella PLP	§3.4	51
`layoutSlots` + `PAGE_LAYOUT_HANDLER`	cambiare slot dei template `VariantConfigurationTemplate`/`CpqConfigurationTemplate` o aggiungere un handler	`feature-libs/product-configurator/rulebased/root/variant/variant-configurator-overview-layout.module.ts:L22-L66`	51
`ConfiguratorUISettingsConfig`, `ConfiguratorCoreConfig`, `CommonConfiguratorUISettingsConfig`	override di debounce, soglie, variant search	§6	50 — config e DI
Facade e servizi (`ConfiguratorCommonsService`, `ConfiguratorCartService`, `ConfiguratorGroupsService`, `ConfiguratorExpertModeService`, `ConfiguratorQuantityService`)	sostituzione via DI (`useClass`/`useExisting`)	`feature-libs/product-configurator/rulebased/core/facade/configurator-commons.service.ts:L98-L119`, `feature-libs/product-configurator/rulebased/core/services/configurator-expert-mode.service.ts:L10-L22`	50
`ConfiguratorBasicEffectService`	helper "to enhance effects without new effects"	`feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic-effect.service.ts:L12-L17`	50
`HttpErrorHandler`	affiancare/sostituire `ConfiguratorBadRequestHandler`	`feature-libs/product-configurator/rulebased/root/http-interceptors/configurator-bad-request.handler.ts:L22-L82`	50
Augmentation `Configurator`, `ProductConfiguratorConfig`, `LAUNCH_CALLER`	estendere modello e config in modo type-safe	`feature-libs/product-configurator/common/core/model/product-configurator.config.ts:L9-L15`, `feature-libs/product-configurator/rulebased/components/config/augmented-config.model.ts:L14-L33`	54 — upgrade-safe

EXTENSION POINT	COME SI USA	RIFERIMENTO	RICETTA
Stili (`$configurator-rulebased-pages` e liste componenti `!default`) e chunk i18n `configurator`	escludere/riscrivere stili, tradurre	`feature-libs/product-configurator/rulebased/_index.scss:L38-L59`, `feature-libs/product-configurator/common/assets/translations/translations.ts:L9-L15`	53 — feature, cart, stili, i18n

Limiti dell'estendibilità:

- Il textfield **non** esporta adapter astratto, connector, facade, state né i token converter: `feature-libs/product-configurator/textfield/core/index.ts:L7-L7` esporta solo il core module (il public API, `feature-libs/product-configurator/textfield/public_api.ts:L7-L10`, espone componenti, core, occ e `TextfieldConfiguratorModule`). Esporta però l'adapter OCC concreto `OccConfiguratorTextfieldAdapter` e le classi converter OCC (normalizer e add-to-cart serializer) — `feature-libs/product-configurator/textfield/occ/index.ts:L7-L9`, `feature-libs/product-configurator/textfield/occ/converters/index.ts:L7-L8`. Usarlo come "template" significa copiarlo, non estenderlo.
- `CpqConfiguratorPageLayoutHandler` non è esportato: `feature-libs/product-configurator/rulebased/root/cpq/index.ts:L7-L10` esporta solo i quattro moduli CPQ, mentre `VariantConfiguratorPageLayoutHandler` è pubblico — `feature-libs/product-configurator/rulebased/root/variant/index.ts:L11-L11`. Per cambiare il comportamento CPQ si registra un proprio `PAGE_LAYOUT_HANDLER` invece di estendere la classe.
- Un nuovo configuratore rulebased richiede in pratica: un `configuratorType` nuovo, route `configure<TYPE>`/`configureOverview<TYPE>` con route Angular `path: null` + `cxRoute`, un adapter nel token multi, un layout per il template CMS. Tutti questi pezzi esistono come pattern nel codice VC/CPQ (§3.1–§3.10); una guida passo-passo non esiste nel repo.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. `CpqConfiguratorRootModule` **protegge tutto lo storefront.** Fornisce `routing.protected: true` come **default** config (sovrascrivibile da `provideConfig` dell'app) — `feature-libs/product-configurator/rulebased/root/cpq/cpq-configurator-root.module.ts:L19-L19` — quindi l'intero storefront diventa protetto, non solo le pagine CPQ, salvo le route configurate con `protected: false` esplicito — `core-libs/core/src/routing/protected-routes/protected-routes.service.ts:L72-L81`.
2. **Update scartati in silenzio.** Se il carrello attivo ha un `code` e non è stabile, `updateConfiguration` (e le container row) non dispatchano nulla; c'è solo un warning in dev mode — `feature-libs/product-configurator/rulebased/core/facade/configurator-commons.service.ts:L139-L151`. Poiché l'add-to-cart del configuratore incrementa i processi del carrello (`feature-libs/product-configurator/rulebased/core/state/actions/configurator-cart.action.ts:L91-L105`), un click su un attributo durante l'add-to-cart viene perso.
3. `loading` **resta true fino al finalize.** `UpdateConfigurationSuccess` non ha meta loader: il flag impostato da `setPendingLoader` resta true fino a `UpdateConfigurationFinalizeSuccess`, emessa solo a processi esauriti — `feature-libs/product-configurator/rulebased/core/state/actions/configurator.action.ts:L203-L209`, `core-libs/core/src/state/utils/loader/loader.reducer.ts:L39-L60`.
4. **CPQ: errori sincroni negli adapter.** `updateConfigurationOverview` e `searchVariants` del CPQ lanciano in modo sincrono; in `updateOverview$` l'eccezione nasce nella project di `mergeMap`, fuori dal `catchError` interno, quindi l'effect va in errore e viene risottoscritto dal `defaultEffectsErrorHandler` di NgRx (max 10 volte) — `feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.adapter.`

ts:L106-L110, feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L377-L380, deps:ngrx-effects-21.0.1/package/fesm2022/ngrx-effects.mjs:L174-L185. `searchVariants` è invece protetto dal filtro tipo VARIANT — feature-libs/product-configurator/rulebased/core/state/effects/configurator-variant.effect.ts:L25-L82.

5. `enableVariantSearch` **undefined.** Se si sovrascrive `productConfigurator` senza la chiave e il tipo è VARIANT, nessuno dei due effect variant emette (uno vuole `=== true`, l'altro gestisce il caso "non attivo"), e `SearchVariants` resta senza success — feature-libs/product-configurator/rulebased/core/state/effects/configurator-variant.effect.ts:L31-L35, :L68-L73.
6. **Placeholder letterale nell'URL CPQ.** `readCpqConfiguration` contiene `?tabId=${tabId}` nel template, ma `tabId` non è passato come urlParam: se è falsy il placeholder resta nell'URL — feature-libs/product-configurator/rulebased/cpq/occ/default-occ-configurator-cpq-config.ts:L25-L26, feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.service.ts:L292-L297, core-libs/core/src/occ/services/occ-endpoints.service.ts:L121-L146.
7. **Match per substring delle chiavi.** La pulizia riconosce le entità con `ownerKey.includes('product')` / `'cartEntry'`: un id contenente "product" farebbe match — feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L668-L670, feature-libs/product-configurator/rulebased/core/state/effects/configurator-cart.effect.ts:L223-L232.
8. `displayOnly` **è una stringa.** L'extractor copia `params.displayOnly` (stringa) in un campo tipizzato boolean: `'false'` sarebbe truthy — feature-libs/product-configurator/common/components/service/configurator-router-extractor.service.ts:L42-L42, feature-libs/product-configurator/common/components/service/configurator-router-data.ts:L17-L17. I link generati dal codice usano `displayOnly` solo con valore true.
9. **Due mapping per** `ConfiguratorForm`**.** `ConfiguratorGroupModule` registra `cmsComponents.ConfiguratorForm → ConfiguratorGroupComponent` e `ConfiguratorFormModule` lo rimappa su `ConfiguratorFormComponent` — feature-libs/product-configurator/rulebased/components/group/configurator-group.module.ts:L61-L68, feature-libs/product-configurator/rulebased/components/form/configurator-form.module.ts:L22-L29. Prevale il form: `ConfiguratorFormModule` importa `ConfiguratorGroupModule` (:L19-L19), Angular raccoglie i provider degli import prima dei propri (angular:packages/core/src/di/provider_collection.ts:L293-L346) e i `DefaultConfigChunk` sono fusi con `deepMerge` in ordine, l'ultimo vince (core-libs/core/src/config/utils/deep-merge.ts:L18-L49, core-libs/core/src/config/services/configuration.service.ts:L56-L89). Se si importa solo `ConfiguratorGroupModule` in un modulo custom, `ConfiguratorForm` diventa il gruppo.
10. **Nomi CMS senza mapping.** `ConfiguratorOverviewMenu` e `ConfiguratorOverviewFilter` stanno nei `cmsComponents` della root feature ma nessun modulo del repo registra un mapping con quelle chiavi — feature-libs/product-configurator/rulebased/root/rulebased-configurator-root-feature.module.ts:L14-L14, :L28-L28. I due componenti sono resi direttamente come elementi dentro la sidebar (`cx-configurator-overview-filter`, `cx-configurator-overview-menu`) e il filtro anche nel dialog filtro — feature-libs/product-configurator/rulebased/components/overview-sidebar/configurator-overview-sidebar.component.html:L35-L40, feature-libs/product-configurator/rulebased/components/overview-filter-dialog/configurator-overview-filter-dialog.component.html:L30-L30.
11. **Typo nelle stringhe action.** `'[Configurator] Create Configuration Sucess'`, `'… Read Configuration Sucess'`, doppio spazio in `SEARCH_VARIANTS_FAIL`, classi `DissmissConflictDialoge`/`CheckConflictDialoge` — feature-libs/product-configurator/rulebased/core/state/actions/configurator.action.ts:L16-L21, feature-libs/product-configurator/rulebased/core/state/actions/configurator-variant.action.ts:L12-L12, feature-libs/product-configurator/rulebased/core/state/actions/configurator.action.ts:L496-L504. Chi filtra le action per stringa (DevTools, meta-reducer) deve usare quelle esatte.
12. `UPDATE_CART_ENTRY_SUCCESS` **morta.** Definita ma mai usata — feature-libs/product-configurator/rulebased/core/state/actions/configurator-cart.action.ts:L29-L29.

13. **Configurazione senza attributi.** `getFirstGroupWithAttributes` lancia `Configuration does not have any attributes`, ed è chiamato in create, cart read, errore update e in `updateConfigurationSuccess$` (quando il gruppo corrente manca o è un conflitto) — feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic-effect.service.ts:L112-L125, feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L440-L445. In create e cart read l'eccezione finisce nel `catchError` interno e diventa un'action `…Fail`; in `updateConfigurationSuccess$` il throw avviene nel `map` senza `catchError`, quindi fa fallire l'effect (che viene risottoscritto dal `defaultEffectsErrorHandler` di NgRx).
14. **Assignment mancante = niente render.** `assignment ?? []` usa un array come mappa; una chiave assente produce solo un warning in dev mode — feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.directive.ts:L37-L39, :L82-L88.
15. **Connector non in root.** `RulebasedConfiguratorConnector` e `ConfiguratorTextfieldConnector` non sono `providedIn: 'root'`: iniettarli fuori dal modulo lazy dà `NullInjectorError` — feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L18-L20, feature-libs/product-configurator/textfield/core/connectors/configurator-textfield.connector.ts:L14-L16.
16. **Handler 400 che inghiotte.** Con toggle CPQ container, `hasMatch` fa match sui 400 product-card ma `handleError` non mostra nulla — feature-libs/product-configurator/rulebased/root/http-interceptors/configurator-bad-request.handler.ts:L35-L48, :L84-L94. Il `BadRequestHandler` del core ha `Priority.LOW` — core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L161-L163 — e `resolveApplicable` sceglie un solo handler, quello a priorità più alta — core-libs/core/src/util/applicable.ts:L50-L57 — quindi sul 400 product-card vince l'handler del configuratore (NORMAL) e il messaggio del core non compare.
17. **Page layout handler e sincronia.** Gli handler VC/CPQ riassegnano `slots$` dentro una `subscribe` con `take(1)`: la sostituzione funziona solo se `extractRouterData()` emette sincronamente — feature-libs/product-configurator/rulebased/root/cpq/cpq-configurator-page-layout-handler.ts:L57-L63, feature-libs/product-configurator/rulebased/root/variant/variant-configurator-page-layout-handler.ts:L41-L67. DA VERIFICARE: dipende dal replay dello stato router.
18. **Textfield: incoerenze.** `UpdateConfiguration` è un `LoaderLoadAction` senza success, quindi `loading` resta true dopo un update locale — feature-libs/product-configurator/textfield/core/state/actions/configurator-textfield.action.ts:L71-L76; `readConfigurationForCartEntry` dispatcha a ogni emissione di `requireLoadedCart()` — feature-libs/product-configurator/textfield/core/facade/configurator-textfield.service.ts:L180-L201; la lettura order entry usa sempre `OCC_USER_ID_CURRENT` e l'endpoint ordine anche per le quote — :L228-L234, feature-libs/product-configurator/textfield/occ/occ-configurator-textfield.adapter.ts:L108-L120; il bottone ha `routerLink` al carrello e `(click)`, quindi naviga senza attendere l'add-to-cart — feature-libs/product-configurator/textfield/components/add-to-cart-button/configurator-textfield-add-to-cart-button.component.html:L1-L5.
19. **Verbi HTTP diversi.** Update cart entry: VC = PUT, textfield = POST — feature-libs/product-configurator/rulebased/occ/variant/variant-configurator-occ.adapter.ts:L239-L241, feature-libs/product-configurator/textfield/occ/occ-configurator-textfield.adapter.ts:L154-L156.
20. **Codice CPQ non usato.** `getCpqAccessData`, `getConfigIdForCartEntry`, `getConfigIdForOrderEntry` non sono usati altrove nel repo — feature-libs/product-configurator/rulebased/cpq/occ/default-occ-configurator-cpq-config.ts:L14-L14, feature-libs/product-configurator/rulebased/cpq/occ/cpq-configurator-occ.service.ts:L82-L122.
21. **Test e `dist/`.** `feature-libs/product-configurator/vitest.config.ts` imposta `process.env['NX_TSCONFIG_PATH']` su `tsconfig.spec.json` prima di `defineConfig`: il commento spiega che altrimenti `nxViteTsPaths` userebbe `tsconfig.lib.json`, che mappa `@spartacus/*` su `dist/`, e dopo una build codice di libreria e helper di test avrebbero copie separate degli injection token (es. `FeatureToggles`) —

feature-libs/product-configurator/vitest.config.ts:L13-L16. La coverage esclude inoltre `textfield/root/**` — feature-libs/product-configurator/vitest.config.ts:L47-L59.

---

10. Come fare debug

- **Owner e tipo.** Quasi ogni bug parte da un `owner` sbagliato. Iscriversi a `ConfiguratorRouterExtractorService.extractRouterData()` e verificare `owner.key`, `configuratorType` e `pageType`; ricordare che non emette senza `entityKey` né durante navigazioni in corso — feature-libs/product-configurator/common/components/service/configurator-router-extractor.service.ts:L28-L34. Un `Not able to determine configurator type` indica un `cxRoute` che non inizia con `configure` — :L101-L113.
- **"No adapter found for configurator type".** Il tipo dall'URL non ha un adapter nel token: tipicamente si è aperta una route CPQ senza aver caricato `RulebasedCpqConfiguratorModule` nel modulo lazy — feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L160-L190, projects/storefrontapp/src/app/spartacus/features/product-configurator/rulebased-configurator-wrapper.module.ts:L12-L21.
- **Redux DevTools.** Nello slice `productConfigurator.configurations.entities[<ownerKey>]` controllare `processesCount` (update in volo), `loading`, `error` e `value.interactionState`. Sequenza attesa per un update: `Update Configuration` → … `Success` → … `Finalize Success` + `Update Price Summary` (capitolo 19). Per un add-to-cart: `Add To Cart` → `Add Next Owner` + `CartAddEntrySuccess` → `Set Next Owner Cart Entry` + `Set Interaction State`.
- **Click ignorati.** Cercare in console (dev mode) il warning `CART_BUSY_NO_UPDATES_MSG` — feature-libs/product-configurator/rulebased/core/facade/configurator-commons.service.ts:L139-L151.
- **Attributo non renderizzato.** Warning dev mode "No attribute type component available for: ..." della direttiva — feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.directive.ts:L82-L88; controllare la chiave calcolata (`AttributeType_` + `uiType` o `uiTypeVariation`) — feature-libs/product-configurator/rulebased/components/group/configurator-group.component.ts:L121-L127 — e il valore normalizzato di `uiType` — feature-libs/product-configurator/rulebased/occ/variant/converters/occ-configurator-variant-normalizer.ts:L440-L461.
- **Network.** VC: `ccpconfigurator/…` (GET create, PATCH update, GET pricing); CPQ: `cpqconfigurator/…` con `tabId` e un PATCH per attributo. Un `${tabId}` letterale nell'URL è la trappola 6 di §9.
- **Configurazione "che si ricrea".** Se dopo un'azione si vede un nuovo `Create Configuration`, una `RemoveConfiguration` sulla chiave product-bound è avvenuta mentre `getOrCreateConfiguration` era ancora sottoscritto (§3.7 e commento in feature-libs/product-configurator/rulebased/components/add-to-cart-button/configurator-add-to-cart-button.component.ts:L448-L458).
- **Messaggio 400 mancante.** Verificare il toggle `productConfiguratorCPQContainer` e la URL della richiesta (product card) — trappola 16.

---

11. Domande di autoverifica

1. **Come decide il connector se usare l'adapter VC o quello CPQ?** Confronta `owner.configuratorType` (ricavato dal suffisso del semanticRoute) con `getConfiguratorType()` di ogni adapter del token multi `CONFIGURATOR_ADAPTER_LIST`; se nessuno combacia lancia errore. — feature-libs/product-configurator/

rulebased/core/connectors/rulebased-configurator.connector.ts:L160-L190, feature-libs/product-configurator/common/components/service/configurator-router-extractor.service.ts:L101-L113.

2. **Perché** `RulebasedConfiguratorConnector` **non è** `providedIn: 'root'`**?** Perché gli adapter sono registrati nel modulo lazy: un connector in root verrebbe creato nell'injector root e non vedrebbe gli adapter lazy. Il core lo fornisce esplicitamente. — feature-libs/product-configurator/rulebased/core/connectors/rulebased-configurator.connector.ts:L18-L18, feature-libs/product-configurator/rulebased/core/rulebased-configurator-core.module.ts:L16-L34.
3. **Che chiave ha nello store la configurazione di un prodotto** `ABC` **dopo l'add-to-cart come entry 2?** Prima `product/ABC`; dopo l'add-to-cart il reducer imposta `nextOwner = cartEntry/2` e `addOwner$` copia l'`interactionState` sull'entità `cartEntry/2`. — feature-libs/product-configurator/common/shared/utils/configurator-model-utils.ts:L19-L27, feature-libs/product-configurator/rulebased/core/state/reducers/configurator.reducer.ts:L290-L305, feature-libs/product-configurator/rulebased/core/state/effects/configurator-cart.effect.ts:L250-L285.
4. **Perché gli update usano** `concatMap` **e non** `switchMap`**?** Ogni update invia un solo attributo cambiato; `switchMap` cancellerebbe richieste in volo perdendo modifiche. `concatMap` le mette in coda. — feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L178-L181.
5. **Quando viene impostato** `isCartEntryUpdateRequired` **e a cosa serve?** A `true` nel finalize di un update, a `false` su `UPDATE_CART_ENTRY`; il bottone "update cart" chiama `updateCartEntry` solo se è true. — feature-libs/product-configurator/rulebased/core/state/reducers/configurator.reducer.ts:L122-L134, :L175-L181, feature-libs/product-configurator/rulebased/components/add-to-cart-button/configurator-add-to-cart-button.component.ts:L463-L482.
6. **Cosa succede se un update fallisce?** `UpdateConfigurationFail` decrementa i processi; a processi esauriti si emette `UpdateConfigurationFinalizeFail`, che `handleErrorOnUpdate$` trasforma in una `ReadConfiguration` del primo gruppo con attributi. — feature-libs/product-configurator/rulebased/core/state/effects/configurator-basic.effect.ts:L516-L585.
7. **Come si aggiunge un componente per un nuovo tipo di attributo?** Registrando in un modulo `provideDefaultConfig({productConfigurator: {assignment: {AttributeType_<tipo>: MioComponente}}})`; il componente riceve `ConfiguratorAttributeCompositionContext` dall'injector creato dalla direttiva. — feature-libs/product-configurator/rulebased/components/attribute/types/radio-button/configurator-attribute-radio-button.module.ts:L33-L43, feature-libs/product-configurator/rulebased/components/attribute/composition/configurator-attribute-composition.directive.ts:L74-L101.
8. **Perché, passando all'overview dopo l'add-to-cart, il codice fa due navigazioni?** La prima, con `replaceUrl: true`, riscrive la voce di history della pagina di configurazione con owner `cartEntry`, così il tasto back torna alla configurazione della entry; la seconda va all'overview. — feature-libs/product-configurator/rulebased/components/add-to-cart-button/configurator-add-to-cart-button.component.ts:L172-L202.
9. **Che effetto collaterale globale ha importare** `CpqConfiguratorRootModule`**?** Fornisce `routing.protected: true` come default config ("force early login", sovrascrivibile da `provideConfig`): l'intera applicazione diventa protetta, salvo le route con `protected: false` esplicito. — feature-libs/product-configurator/rulebased/root/cpq/cpq-configurator-root.module.ts:L16-L21.
10. **In cosa differisce lo store del textfield da quello rulebased?** Il textfield ha un singolo `LoaderState` (una configurazione alla volta) e l'update è solo locale; il rulebased ha un `EntityProcessesLoaderState` indicizzato per owner key con update inviati al backend. — feature-libs/product-configurator/textfield/core/state/configuration-textfield-state.ts:L10-L20, feature-libs/product-configurator/textfield/core/facade/configurator-textfield.service.ts:L81-L101, feature-libs/product-configurator/rulebased/core/state/configurator-state.ts:L10-L19.

Riferimenti allo SHA `5b7a1c2bf2808d7380bc20596d10f4fa710c3da1` (vedi 00-meta).

1. A cosa serve e perché esiste

Questo capitolo copre tre feature library "di account" che vivono sotto `feature-libs/` e che condividono la stessa architettura a quattro strati (`root` eager, `core`, `occ`, `components` lazy), ma la usano in modi molto diversi:

LIBRERIA	PACCHETTO	COSA FA PER L'UTENTE	TRATTO ARCHITETTURALE DISTINTIVO
Quote	`@spartacus/quote`	negoziazione B2B di un preventivo tra buyer e seller (richiesta dal carrello, commenti, sconti, scadenza, checkout della quote)	macchina a stati guidata dal backend (`allowedActions`), "quote cart" che sostituisce il carrello attivo, guard CMS che blocca la navigazione, tre chunk lazy distinti
Customer ticketing	`@spartacus/customer-ticketing`	ticket di assistenza in My Account: lista, creazione, messaggi, allegati, chiusura e riapertura	`Command` con strategia `Queue`, orchestrazione tramite eventi (`CxEvent`) ascoltati da un listener eager
Subscription billing	`@spartacus/subscription-billing`	elenco e dettaglio degli abbonamenti, azioni (cancel/withdraw/resubscribe/extend), fatture, prezzi "a piano" in PDP e carrello	componenti standalone con signals, facade che restituiscono Observable freddi, outlet del carrello forniti dal modulo root eager

Tutte e tre le librerie seguono il pattern descritto in 12 — Feature module e lazy loading: il modulo `*RootModule` viene importato eagerly e dichiara `featureModules` (componenti CMS → nome feature), route e facade proxy; il resto (`*Module` = components + core + occ) viene caricato on demand. La facade lazy (`facadeFactory`) e il pattern Command/Query sono quelli di 20 — Facade, Command/Query, eventi; gli adapter OCC seguono 21 — OCC.

Quote è la più complessa e la più interessante: lo stato di una quote (17 valori di `QuoteState`, `feature-libs/quote/root/model/quote.model.ts:L75-L93`) e le azioni possibili (`allowedActions`) arrivano dal backend, ma Spartacus le **filtra, riordina e classifica** lato client con configurazione (`feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L30-L53`) e collega la quote al carrello: quando il buyer modifica o compra una quote, il carrello attivo diventa il "quote cart" e un guard CMS impedisce di uscire dal flusso (`feature-libs/quote/components/cart-guard/quote-cart.guard.ts:L34-L57`). Per questo il capitolo dedica la maggior parte dello spazio a quote, e tratta ticketing e subscription billing per le differenze.

Prerequisiti utili: 25 — Cart (active cart, multi-cart, saved cart), 26 — Checkout, 18 — Layout, breakpoint, launch dialog (i dialog `LAUNCH_CALLER`), 17 — Outlet, 41 — Errori e global message (`HttpErrorHandler`).

2. Mappa dei file

2.1 `feature-libs/quote`

PATH	RUOLO
`feature-libs/quote/quote.module.ts`	`QuoteModule` = `QuoteComponentsModule` + `QuoteCoreModule` + `QuoteOccModule` (target del lazy load feature `quote`)
`feature-libs/quote/root/feature-name.ts`	tre nomi feature: `quote`, `quote_cart_guard`, `quote_request`

PATH	RUOLO
feature-libs/quote/root/quote-root.module.ts	eager: mapping CMS → feature, route quotes/quoteDetails, layout QuoteDetailsPageTemplate, ng-route con AuthGuard+CmsPageGuard, due HttpErrorHandler
feature-libs/quote/root/facade/quote.facade.ts	QuoteFacade astratta + proxy lazy (8 metodi proxati)
feature-libs/quote/root/model/quote.model.ts	Quote, QuoteAction, QuoteActionType, QuoteState, QuoteRoleType, QuoteDiscountType, QuoteMetadata, QuoteStarter
feature-libs/quote/root/model/augmented-types.ts	augment di OrderEntry.comments e di LAUNCH_CALLER.QUOTE_ACTION_CONFIRMATION
feature-libs/quote/root/http-interceptors/quote-bad-request.handler.ts	QuoteBadRequestHandler (400 legati alle quote)
feature-libs/quote/root/http-interceptors/quote-not-found.handler.ts	QuoteNotFoundHandler (404 Quote not found → redirect a quotes)
feature-libs/quote/root/config/quote.config.ts	QuoteConfig vuota agganciata a Config.quote
feature-libs/quote/core/quote-core.module.ts	facade provider, QuoteConnector, defaultQuoteCoreConfig, istanzia QuoteCartEventListener
feature-libs/quote/core/facade/quote.service.ts	QuoteService: tutti i command e le query
feature-libs/quote/core/facade/facade-providers.ts	QuoteFacade → useExisting: QuoteService
feature-libs/quote/core/config/quote-core.config.ts, default-quote.core.config.ts	QuoteCoreConfig.quote.actions (primarie e ordine per stato)
feature-libs/quote/core/connectors/quote.adapter.ts, quote.connector.ts, converters.ts	adapter astratto (9 operazioni), connector 1:1, 7 token di conversione
feature-libs/quote/core/event/quote.events.ts, quote-cart-event.listener.ts	QuoteDetailsReloadQueryEvent e traduzione eventi carrello → reload
feature-libs/quote/core/services/quote-cart.service.ts	QuoteCartService: "il carrello attivo è un quote cart?", checkoutAllowed
feature-libs/quote/core/services/cart-utils.service.ts	CartUtilsService.handleCartAndGoToQuoteList
feature-libs/quote/core/services/quote-storefront-utils.service.ts	accesso DOM SSR-safe
feature-libs/quote/occ/quote-occ.module.ts	QuoteAdapter → OccQuoteAdapter, normalizer multi su QUOTE_NORMALIZER
feature-libs/quote/occ/adapters/occ-quote.adapter.ts	chiamate HTTP verso users/${userId}/quotes...
feature-libs/quote/occ/config/default-occ-quote-config.ts	10 endpoint di default
feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts	filtro/ordine/primarietà delle azioni, calcolo isEditable
feature-libs/quote/occ/converters/occ-quote-entry-normalizer.ts	quoteCode sulle entry, PRODUCT_NORMALIZER sui prodotti

PATH	RUOLO
feature-libs/quote/components/quote-components.module.ts	aggregatore di 12 moduli UI + defaultQuoteUIConfig
feature-libs/quote/components/config/quote-ui.config.ts, default-quote-ui.config.ts	QuoteUIConfig (commenti, troncamento, dialog di conferma, sconto, debounce)
feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts	bottoni azione, logica dialog di conferma
feature-libs/quote/components/summary/seller-edit/*	sconto e scadenza (lato seller)
feature-libs/quote/components/header/*	testata, form buyer (nome, descrizione)
feature-libs/quote/components/items/*	entry: da quote, saved cart read-only o active cart
feature-libs/quote/components/list/*	lista quote (AccountMyQuotesComponent)
feature-libs/quote/components/links/*	link: nuovo carrello, download PDF proposta, ordine
feature-libs/quote/components/comments/*	messaggistica buyer/seller
feature-libs/quote/components/confirm-dialog/*	QuoteConfirmDialogComponent + layout QUOTE_ACTION_CONFIRMATION
feature-libs/quote/components/cart-guard/*	entry point secondario: QuoteCartGuardComponent marker + QuoteCartGuard
feature-libs/quote/components/request-button/*	entry point secondario: QuoteRequestButtonComponent (componente CMS QuoteRequestComponent)
projects/storefrontapp/src/app/spartacus/features/quote-feature.module.ts	wiring demo: tre import() distinti
core-libs/schematics/src/shared/lib-configs/quote-schematics-config.ts	configurazione schematics (b2b, dipendenza da cart base)

2.2 feature-libs/customer-ticketing

PATH	RUOLO
feature-libs/customer-ticketing/customer-ticketing.module.ts	CustomerTicketingModule = components + core + occ
feature-libs/customer-ticketing/root/customer-ticketing-root.module.ts	6 componenti CMS, alias feature core, due ng-route, CustomerTicketingEventModule
feature-libs/customer-ticketing/root/customer-ticketing-constants.ts	limiti (5000/255 caratteri, 10 MB, 1 allegato, page size 5)
feature-libs/customer-ticketing/root/config/*	CustomerTicketingConfig, default, routing
feature-libs/customer-ticketing/root/events/customer-ticketing.events.ts	eventi reset/reload query ed eventi di dominio
feature-libs/customer-ticketing/root/events/customer-ticketing-event.listener.ts	listener eager: messaggi e reload/reset
feature-libs/customer-ticketing/root/facade/customer-ticketing.facade.ts	facade lazy (12 metodi)

PATH	RUOLO
feature-libs/customer-ticketing/root/model/customer-ticketing.model.ts	STATUS, STATUS_NAME, TicketDetails, TicketEvent
feature-libs/customer-ticketing/root/model/augmented-core.model.ts	LAUNCH_CALLER.CUSTOMER_TICKETING_*
feature-libs/customer-ticketing/core/customer-ticketing-core.module.ts	facade, connector, NotFoundTicketRequestHandler, CustomerTicketingPageMetaResolver
feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts	CustomerTicketingService (command Queue, query)
feature-libs/customer-ticketing/core/http-interceptors/handlers/not-found-ticket-request.handler.ts	404 sul dettaglio → lista
feature-libs/customer-ticketing/core/services/customer-ticketing-page-meta.resolver.ts	heading e breadcrumb del dettaglio
feature-libs/customer-ticketing/occ/adapters/occ-customer-ticketing.adapter.ts	HTTP, FormData per upload
feature-libs/customer-ticketing/occ/config/default-occ-customer-ticketing-config.ts	endpoint
feature-libs/customer-ticketing/components/shared/customer-ticketing-dialog/*	CustomerTicketingDialogComponent astratta + layout dei tre dialog
feature-libs/customer-ticketing/components/details/*	dettagli, messaggi, close, reopen
feature-libs/customer-ticketing/components/list/*	lista e create
feature-libs/customer-ticketing/components/my-account-v2/*	widget "ultimo ticket"
projects/storefrontapp/src/app/spartacus/features/customer-ticketing/customer-ticketing-wrapper.module.ts	wrapper demo che aggiunge CDP se environment.cdp

2.3 feature-libs/subscription-billing

PATH	RUOLO
feature-libs/subscription-billing/subscription-billing.module.ts	SubscriptionBillingModule = components + core + occ
feature-libs/subscription-billing/root/subscription-billing-root.module.ts	5 componenti CMS, alias core, routing, **due outlet del carrello** (eager)
feature-libs/subscription-billing/root/components/cart/*	SubscriptionCartPriceHeadingComponent, SubscriptionCartPriceBodyComponent (standalone, eager)
feature-libs/subscription-billing/root/services/subscription-product.service.ts	SubscriptionProductService: riconosce i prodotti subscription
feature-libs/subscription-billing/root/model/subscription-product.model.ts	augment di Product e ProductScope.SUBSCRIPTION
feature-libs/subscription-billing/root/model/subscription.model.ts	SubscriptionDetail, SubscriptionActionMode, LAUNCH_CALLER aggiuntivi
feature-libs/subscription-billing/root/facade/*	SubscriptionFacade, SubscriptionBillingFacade, SubscriptionActionsFacade
feature-libs/subscription-billing/root/config/extend-subscription-dropdown-options-config.ts	ExtendSubscriptionFrequencyDropdownOptionsConfig

PATH	RUOLO
feature-libs/subscription-billing/root/events/subscription-billing-event.listener.ts	reload su cambio lingua/valuta
feature-libs/subscription-billing/core/facade/*	SubscriptionService, SubscriptionBillingService, SubscriptionActionsService, facade provider
feature-libs/subscription-billing/core/connector/*	tre coppie adapter/connector
feature-libs/subscription-billing/core/services/*	due page meta resolver
feature-libs/subscription-billing/occ/adapters/*	tre adapter OCC (senza converter)
feature-libs/subscription-billing/occ/config/default-occ-subscription-billing-config.ts	endpoint + scope prodotto subscription
feature-libs/subscription-billing/components/actions-modal/*	dialog azioni (signals, effect)
feature-libs/subscription-billing/components/list/*	lista subscription, lista bill, DateRangeModalComponent
feature-libs/subscription-billing/components/product/*	prezzo e usage charge in PDP

File aggiuntivi

PATH	RUOLO
feature-libs/quote/public_api.ts	Entry @spartacus/quote: riferimento triple-slash a types.d.ts (per @HostListener con eventi tipo keydown.Escape) + riesportazione di quote.module (:L14-L19).
feature-libs/quote/schematics/add-quote/index.ts	addQuoteFeatures(): factory degli schematics ng-add/add di @spartacus/quote (vedi 3.12).
feature-libs/quote/schematics/add-quote/index_spec.ts	Test dello schematic, incluso il controllo che la configurazione b2b venga aggiunta.
feature-libs/quote/schematics/constants.ts	Costanti schematics (QUOTE_FOLDER_NAME, QUOTE_TRANSLATIONS, ...), duplicate di quelle in core-libs schematics (vedi 3.12).
feature-libs/quote/vitest.config.ts	Config Vitest: jsdom, pool forks, alias per mock feature directive e url-testing.module, coverage 85/65.
feature-libs/quote/_index.scss	Entry SCSS: core + app Spartacus, mixin locale visible-focus, poi styles/index.
feature-libs/quote/styles/_index.scss	Importa mixin, 12 file componente e layout; $quote-components-allowlist con @extend.
feature-libs/quote/styles/_quote-comments.scss	Placeholder %cx-quote-comments.
feature-libs/quote/styles/_quote-confirm-dialog.scss	Placeholder %cx-quote-confirm-dialog.
feature-libs/quote/styles/_quote-header-buyer-edit.scss	Placeholder %cx-quote-header-buyer-edit (importa lo stile card).

PATH	RUOLO
feature-libs/quote/styles/_quote-header-overview.scss	Placeholder %cx-quote-header-overview + regole RTL.
feature-libs/quote/styles/_quote-items.scss	Placeholder %cx-quote-items.
feature-libs/quote/styles/_quote-links.scss	Placeholder %cx-quote-links + regole LTR/RTL.
feature-libs/quote/styles/_quote-list.scss	Placeholder %cx-quote-list + regole LTR/RTL.
feature-libs/quote/styles/_quote-request-button.scss	Placeholder %cx-quote-request-button.
feature-libs/quote/styles/_quote-summary-actions.scss	Placeholder %cx-quote-summary-actions.
feature-libs/quote/styles/_quote-summary-prices.scss	Placeholder %cx-quote-summary-prices.
feature-libs/quote/styles/_quote-summary-seller-edit.scss	Placeholder %cx-quote-summary-seller-edit.
feature-libs/quote/styles/_quote-summary.scss	Placeholder %cx-quote-summary.
feature-libs/quote/styles/layout/_index.scss	Allowlist/blocklist del page template QuoteDetailsPageTemplate (variabili con suffisso -store-finder, vedi 3.12).
feature-libs/quote/styles/layout/_quote-details-page.scss	Placeholder %QuoteDetailsPageTemplate: flex 70/30 tra BodyContent e CenterRightContent.
feature-libs/quote/styles/mixins/_mixins.scss	Importa i due mixin sotto.
feature-libs/quote/styles/mixins/_ghost-bar.scss	Mixin cx-ghost-bar.
feature-libs/quote/styles/mixins/_quote-toggle.scss	Mixin cx-quote-toggle.
feature-libs/customer-ticketing/_index.scss	Entry SCSS: core + blocco modal di cxbase + styles/index.
feature-libs/customer-ticketing/vitest.config.ts	Config Vitest: alias @spartacus/core/testing/mock-feature-toggles, coverage 85/65.
feature-libs/subscription-billing/public_api.ts	Entry @spartacus/subscription-billing: riesporta subscription-billing.module (il commento dice "segment", residuo di copia).
feature-libs/subscription-billing/assets/public_api.ts	Entry assets: riesporta translations/translations.
feature-libs/subscription-billing/vitest.config.ts	Config Vitest senza alias, coverage 85/65.
feature-libs/subscription-billing/_index.scss	Entry SCSS: importa solo styles/index.
feature-libs/subscription-billing/styles/_index.scss	Importa core + 10 file componente; $subscription-billing-components-allowlist con @extend.
feature-libs/subscription-billing/styles/billing-details/_subscription-billing-details.scss	Placeholder %cx-subscription-billing-details.
feature-libs/subscription-billing/styles/cart/_subscription-cart-item-list.scss	Placeholder %cx-subscription-cart-item-list.

PATH	RUOLO
feature-libs/subscription-billing/styles/cart/_subscription-cart-price-body.scss	Placeholder %cx-subscription-cart-price-body (outlet carrello eager).
feature-libs/subscription-billing/styles/details/_subscription-details.scss	Placeholder %cx-subscription-details.
feature-libs/subscription-billing/styles/list/_billing-list.scss	Placeholder %cx-billing-list.
feature-libs/subscription-billing/styles/list/_date-range-modal.scss	Placeholder %cx-date-range-modal.
feature-libs/subscription-billing/styles/list/_subscription-list.scss	Placeholder %cx-subscription-list (e regole condivise con %cx-subscription-details).
feature-libs/subscription-billing/styles/modal/_subscription-modal.scss	Placeholder %cx-subscription-actions-modal.
feature-libs/subscription-billing/styles/product/_subscription-product-price.scss	Placeholder %cx-subscription-product-price.
feature-libs/subscription-billing/styles/product/_subscription-product-usage-charge.scss	Placeholder %cx-subscription-product-usage-charge.

3. Come funziona passo per passo

3.1 Quote: packaging in tre chunk

La lib quote ha **tre** nomi feature (feature-libs/quote/root/feature-name.ts:L7-L9). defaultQuoteComponentsConfig assegna sei componenti CMS (lista, link, commenti, testata, entry, summary) alla feature quote (feature-libs/quote/root/quote-root.module.ts:L29-L44), mentre QuoteCartGuardComponent e QuoteRequestComponent vanno su feature separate (feature-libs/quote/root/quote-root.module.ts:L46-L64). Il motivo è il peso: il bottone "Request quote" sta nella pagina carrello e il marker del guard sta (presumibilmente) in carrello e checkout; caricarli non deve trascinare tutto il chunk quote.

Nell'app demo le tre feature corrispondono a tre import() distinti: @spartacus/quote, @spartacus/quote/components/cart-guard, @spartacus/quote/components/request-button (projects/storefrontapp/src/app/spartacus/features/quote-feature.module.ts:L26-L63). I due chunk piccoli sono entry point ng-packagr secondari e infatti components/public_api.ts non li riesporta (feature-libs/quote/components/public_api.ts:L7-L15).

QuoteModule importa solo components, core e occ (feature-libs/quote/quote.module.ts:L12-L15). Lo schematics marca la lib come b2b e dipendente da cart base (core-libs/schematics/src/shared/lib-configs/quote-schematics-config.ts:L36-L84).

3.2 Quote: root eager (route, layout, error handler)

- Route semantiche: quotes → my-account/quotes e quoteDetails → my-account/quote/:quoteId (feature-libs/quote/root/quote-root.module.ts:L66-L78).
- Layout: QuoteDetailsPageTemplate con slot BodyContent e CenterRightContent (feature-libs/quote/root/quote-root.module.ts:L80-L86).

- Solo `quoteDetails` ha una ng-route esplicita (`path: null`, risolta dalla config di routing come spiegato in 14 — Routing), protetta da `AuthGuard` e `CmsPageGuard`; `quotes` è una content page CMS (`feature-libs/quote/root/quote-root.module.ts:L88-L106`).
- Due `HttpErrorHandler` multi: `QuoteBadRequestHandler` e `QuoteNotFoundHandler` (`feature-libs/quote/root/quote-root.module.ts:L108-L118`).

Gli handler sono registrati nel root perché devono esistere anche prima del caricamento lazy. Comunque `HttpErrorInterceptor` li raccoglie con `UnifiedInjector.getMulti(HttpErrorHandler)`, quindi vedrebbe anche provider di moduli lazy (`core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L26-L28`). Il `hasMatch` base confronta solo lo status (`core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts:L42-L44`); i due handler quote lo restringono:

- `QuoteBadRequestHandler` (400) fa match solo se l'errore è "legato alle quote" (`feature-libs/quote/root/http-interceptors/quote-bad-request.handler.ts:L28-L32`): tipi OCC `QuoteUnderThresholdError`, `CartValidationError`, `CartQuoteAccessError` (`feature-libs/quote/root/http-interceptors/quote-bad-request.handler.ts:L83-L101`), oppure `IllegalArgumentError` con messaggio che corrisponde a `/Discount type is absolute/` o `/Invalid quote expiration time/` (`feature-libs/quote/root/http-interceptors/quote-bad-request.handler.ts:L121-L133`). `handleError` aggiunge un global message per ogni categoria presente (`feature-libs/quote/root/http-interceptors/quote-bad-request.handler.ts:L34-L52`). Priorità `Priority.NORMAL` (`feature-libs/quote/root/http-interceptors/quote-bad-request.handler.ts:L54-L56`).
- `QuoteNotFoundHandler` (404) fa match solo per `NotFoundError` con messaggio esatto `'Quote not found'` e naviga a `quotes` (`feature-libs/quote/root/http-interceptors/quote-not-found.handler.ts:L29-L60`). Il JSDoc spiega lo scenario: fine di un'emulazione ASM mentre si guarda una quote, poi emulazione di un altro utente (`feature-libs/quote/root/http-interceptors/quote-not-found.handler.ts:L44-L50`).

3.3 Quote: la facade e il suo proxy

`QuoteFacade` è `providedIn: 'root'` con `useFactory: () => facadeFactory({...})`, feature `quote`, otto metodi proxati (`feature-libs/quote/root/facade/quote.facade.ts:L21-L38`). La classe astratta dichiara però anche `requote` e `downloadAttachment` (`feature-libs/quote/root/facade/quote.facade.ts:L99-L134`), che **non** sono nella lista `methods`. `FacadeFactoryService.create` costruisce il proxy come istanza di una sottoclasse vuota e definisce solo i metodi elencati (`core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L110-L131`): sul proxy `requote` è quindi il metodo astratto, cioè `undefined` a runtime (vedi §9).

Nel chunk lazy, `QuoteCoreModule` fornisce `QuoteFacade` con `useExisting: QuoteService` (`feature-libs/quote/core/facade/facade-providers.ts:L11-L17`), registra `QuoteConnector` e `defaultQuoteCoreConfig`, e istanzia nel costruttore `QuoteCartEventListener` (`feature-libs/quote/core/quote-core.module.ts:L14-L25`). I componenti dichiarati nel chunk `quote` ricevono quindi `QuoteService` direttamente; quelli dei chunk `cart-guard` e `request-button` passano dal proxy.

3.4 Quote: modello di dominio

`Quote` è derivato da `OccQuote`: `allowedActions` passa da array di tipi a `QuoteAction[]` (`{type, isPrimary}`) e si aggiunge `isEditable` (`feature-libs/quote/root/model/quote.model.ts:L41-L49`). Le azioni sono 14 (`QuoteActionType`, `feature-libs/quote/root/model/quote.model.ts:L58-L73`); gli stati 17 con prefisso di ruolo (BUYER_, SELLER_, SELLERAPPROVER_) più `CREATED`, `CANCELLED`, `EXPIRED` (`feature-libs/quote/root/model/quote.model.ts:L75-L93`). `QuoteRoleType` ha `ALL`, `BUYER`, `SELLER`, `SELLERAPPROVER`; `QuoteDiscountType` ha `PERCENT` e `ABSOLUTE` (`feature-libs/quote/root/model/quote.model.ts:L95-L105`).

Dettagli notevoli:

- `QuoteMetadata.expirationTime` è `string` di proposito, per inviare l'offset locale (`+02:00`) invece di UTC (feature-libs/quote/root/model/quote.model.ts:L120-L128).
- `QuoteStarter` contiene `cartId` (creazione dal carrello) o `quoteCode` (requote) (feature-libs/quote/root/model/quote.model.ts:L130-L133).
- `QuotesStateParams` passa pagina e sort come Observable (feature-libs/quote/root/model/quote.model.ts:L137-L140).
- `augmented-types.ts` aggiunge `comments` a `OrderEntry` e il valore `QUOTE_ACTION_CONFIRMATION` a `LAUNCH_CALLER`, sia nel tipo sia a runtime (feature-libs/quote/root/model/augmented-types.ts:L10-L23).

3.5 Quote: normalizzazione delle azioni (il cuore della "macchina a stati")

Il backend decide quali azioni sono possibili; il client decide **quali mostrare, in che ordine e con che enfasi**. `QuoteOccModule` registra due normalizer multi su `QUOTE_NORMALIZER`: `OccQuoteActionNormalizer` e `OccQuoteEntryNormalizer` (feature-libs/quote/occ/quote-occ.module.ts:L17-L37).

`OccQuoteActionNormalizer.convert` (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L30-L53):

1. Se esiste un ordine configurato per lo stato (`quote.actions.actionsOrderByState[state]`), clona la lista; se lo stato non è `BUYER_OFFER` e il carrello attivo è il quote cart **di questa quote**, toglie `EDIT` dalla lista clonata (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L60-L81).
2. Filtra le azioni OCC tenendo solo quelle presenti nell'ordine e le ordina di conseguenza; se non c'è ordine per lo stato restituisce la lista OCC invariata (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L82-L89).
3. Marca `isPrimary` se il tipo è in `quote.actions.primaryActions` (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L46-L53).
4. Calcola `isEditable = OCC permette EDIT && EDIT non è più tra le azioni visualizzate` (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L37-L43). Tradotto: `isEditable` è vero quando OCC permette `EDIT` ma `EDIT` non è tra le azioni normalizzate. Il caso tipico è la quote già nel quote cart attivo (EDIT rimosso dal normalizer); vale però anche per gli stati il cui ordine configurato non contiene `EDIT` (con i default `EXPIRED` e `CANCELLED`), dove `EDIT` viene filtrato via (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L82-L83, feature-libs/quote/core/config/default-quote.core.config.ts:L30-L31). Che OCC mandi `EDIT` per `EXPIRED` è previsto dalla UI config, che ha un dialog `EXPIRED.EDIT` (feature-libs/quote/components/config/default-quote-ui.config.ts:L41-L43).

I default (feature-libs/quote/core/config/default-quote.core.config.ts:L10-L37): primarie `APPROVE`, `CHECKOUT`, `SUBMIT`, `REQUOTE`; ordine per sei stati: `BUYER_DRAFT` [SUBMIT, EDIT, CANCEL], `BUYER_OFFER` [CHECKOUT, EDIT, CANCEL], `CANCELLED` [REQUOTE], `EXPIRED` [REQUOTE, CANCEL], `SELLER_REQUEST` e `SELLER_DRAFT` [SUBMIT, EDIT].

`OccQuoteEntryNormalizer` aggiunge `quoteCode` a ogni entry e normalizza il prodotto con `PRODUCT_NORMALIZER` (feature-libs/quote/occ/converters/occ-quote-entry-normalizer.ts:L24-L33).

3.6 Quote: `QuoteService`, command e query

Tutti i command usano `CommandStrategy.CancelPrevious` (feature-libs/quote/core/facade/quote.service.ts:L127-L129), che processa via `switchMap` e completa il notifier del comando cancellato (core-libs/core/src/util/command-query/command.service.ts:L73-L92). `Command.execute` è eager: accoda il comando e ritorna un `ReplaySubject`, quindi la richiesta parte anche se il chiamante non si sottoscrive (core-libs/core/src/util/command-query/command.service.ts:L120-L131).

Un `BehaviorSubject` `isActionPerforming$` (feature-libs/quote/core/facade/quote.service.ts:L82-L85) viene OR-ato con `loading` della query dettagli in `getQuoteDetailsQueryState`, così la UI mostra lo spinner durante le azioni; `getQuoteDetails` emette solo quote caricate e definite (feature-libs/quote/core/facade/quote.service.ts:L535-L554).

Creazione (`createQuoteCommand`, feature-libs/quote/core/facade/quote.service.ts:L90-L125): prende `userId` e l'id del carrello attivo, POST `createQuote` con `{ cartId }`, poi PATCH `editQuote` con i metadata, carica il quote cart come attivo (`multiCartFacade.loadCart` con `extraData: { active: true }`) e dispatcha `QuoteDetailsReloadQueryEvent`.

Azione (`performQuoteActionCommand`, feature-libs/quote/core/facade/quote.service.ts:L230-L298): imposta `isActionPerforming$`, POST `/action`, poi dirama:

- `SUBMIT`/`CANCEL` → `cartUtilsService.handleCartAndGoToQuoteList(isEditable)` (feature-libs/quote/core/facade/quote.service.ts:L244-L251), che se la quote era in edit crea un nuovo carrello prima di navigare a `quotes` (feature-libs/quote/core/services/cart-utils.service.ts:L52-L62);
- `REJECT`/`APPROVE` → `go({ cxRoute: 'quotes' })` (feature-libs/quote/core/facade/quote.service.ts:L252-L259);
- `EDIT`/`CHECKOUT` → `saveActiveCart()`, poi `loadQuoteCartAndProceed`; se la quote non ha ancora `cartId` la rilegge dal backend (feature-libs/quote/core/facade/quote.service.ts:L260-L292);
- errore → `triggerReloadAndCompleteAction` + `handleError` (feature-libs/quote/core/facade/quote.service.ts:L295-L298). `handleError` trasforma `CommerceQuoteExpirationTimeError` in messaggio `quote.httpHandlers.expired` + `EMPTY`, altrimenti rilancia (feature-libs/quote/core/facade/quote.service.ts:L306-L315).

`saveActiveCart` salva come saved cart il carrello attivo solo se non vuoto e non già quote cart, avvisando l'utente (feature-libs/quote/core/facade/quote.service.ts:L461-L487): entrare in una quote non distrugge il carrello normale.

`loadQuoteCartAndProceed` (feature-libs/quote/core/facade/quote.service.ts:L330-L354) carica il cart come attivo, attende che `activeCartFacade.getActive()` emetta quel codice, poi: per `CHECKOUT` chiama `quoteCartService.setCheckoutAllowed(true)` e va a `checkout`; per `REQUOTE` va a `quoteDetails` con il nuovo id.

Requote (`requoteCommand`, feature-libs/quote/core/facade/quote.service.ts:L362-L386): POST `createQuote` con `{ quoteCode }`, salva il carrello attivo e procede con il flusso `REQUOTE`.

Commenti e sconti: `addQuoteCommentCommand` sceglie commento di entry o di testata in base a `entryNumber` e non ricarica (lo fa il componente) (feature-libs/quote/core/facade/quote.service.ts:L171-L186); `addDiscountCommand` ricarica in successo e in errore (feature-libs/quote/core/facade/quote.service.ts:L203-L216). `downloadAttachment` non è un command ma una pipe `takeUserId` + `mergeMap` (feature-libs/quote/core/facade/quote.service.ts:L556-L569).

Query dettagli (feature-libs/quote/core/facade/quote.service.ts:L388-L421): attende una prima emissione del carrello attivo (serve al normalizer per sapere se la quote è collegata al quote cart), poi legge `quoteId` dai parametri router solo quando `nextState === undefined` e l'utente è loggato; si ricarica su `QuoteDetailsReloadQueryEvent` e `LoginEvent`.

Query lista (feature-libs/quote/core/facade/quote.service.ts:L423-L449): reagisce a `currentPage$`/`sort$` dentro il loader, usa `viewConfig.view.defaultPageSize`, `reloadOn: []`, `resetOn: [LoginEvent]`.

Reload da carrello: `QuoteCartEventListener` traduce `CartAddEntrySuccessEvent`, `CartUpdateEntrySuccessEvent`, `CartRemoveEntrySuccessEvent` in `QuoteDetailsReloadQueryEvent` (feature-libs/quote/core/event/quote-cart-event.listener.ts:L29-L49), l'unico evento della lib (feature-libs/quote/core/event/quote.events.ts:L9-L14): modificare il quote cart aggiorna subito i totali della quote.

3.7 Quote: quote cart e guard

`QuoteCartService` deriva "il carrello attivo è un quote cart" da `cart.quoteCode !== undefined` e tiene `checkoutAllowed` in un `ReplaySubject(1)` inizializzato a `false` (feature-libs/quote/core/services/quote-cart.service.ts:L18-L45).

`QuoteCartGuardComponent` è un **marker** con template vuoto (feature-libs/quote/components/cart-guard/quote-cart-guard.component.ts:L10-L17); il suo mapping CMS dichiara `guards: [QuoteCartGuard]` (feature-libs/quote/components/cart-guard/quote-cart-guard.component.module.ts:L16-L23). Così ogni pagina CMS che contiene il marker eredita il guard tramite `CmsPageGuard` (meccanismo dei guard di componente in 15 — CMS core). `QuoteCartGuard.canActivate` restituisce un `UrlTree` verso `quoteDetails` se il quote cart è attivo e la navigazione non è un checkout consentito (feature-libs/quote/components/cart-guard/quote-cart.guard.ts:L34-L57). "Checkout consentito" = (prossima route semantica che inizia con `checkout` OPPURE route corrente di checkout senza prossima route) E `isCheckoutAllowed` (feature-libs/quote/components/cart-guard/quote-cart.guard.ts:L67-L80). In quali pagine sia posizionato il marker dipende dai dati CMS del backend: `DA VERIFICARE` (non presente nel repo).

3.8 Quote: componenti principali

Request button — `QuoteRequestButtonComponent` (componente CMS `QuoteRequestComponent`, feature-libs/quote/components/request-button/quote-request-button.module.ts:L16-L22) mostra il bottone solo agli utenti loggati: non usa `AuthGuard` per non proteggere l'intera pagina carrello (feature-libs/quote/components/request-button/quote-request-button.component.ts:L32-L37). Il click chiama `quoteFacade.createQuote({})` e naviga a `quoteDetails` con il codice ottenuto (feature-libs/quote/components/request-button/quote-request-button.component.ts:L43-L57).

Summary actions — `QuoteSummaryActionsComponent`:

- filtra via `DOWNLOAD_QUOTE_PROPOSAL_DOCUMENT` (diventa un link) (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L421-L425);
- rende un bottone per azione con label `quote.summary.actions.<TYPE>` e `[disabled]` (feature-libs/quote/components/summary/actions/quote-summary-actions.component.html:L8-L14);
- disabilita `SUBMIT` (e `REQUOTE` se il toggle `showWarningMessageOnRequoteButtonClick` è attivo) quando `totalPrice.value` è sotto la soglia (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L219-L232); all'init mostra il warning `quote.commons.minRequestInitiationNote` se un'azione va disabilitata (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L99-L117);
- stile: `btn-primary` se `isPrimary`; con più di due bottoni `CANCEL` diventa `btn-tertiary` (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L330-L343);
- `onClick` esegue subito se non serve conferma, altrimenti apre il dialog e attende la chiusura (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L241-L257). Il config del dialog si cerca per stato → ruolo (derivato dal prefisso dello stato) → `ALL` (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L349-L363, feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L411-L419). Il dialog è `LAUNCH_CALLER.QUOTE_ACTION_CONFIRMATION`; l'azione parte solo se il reason di chiusura è `'yes'` (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L267-L299). `REQUOTE` passa da `quoteFacade.requote`, tutte le altre da `performQuoteAction` (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L259-L265).

Il layout del dialog è `inline`, `DIALOG_TYPE.DIALOG`, con `QuoteConfirmDialogComponent` (feature-libs/quote/components/confirm-dialog/default-quote-confirm-dialog.config.ts:L10-L18), che legge il context da `launchDialogService.data$` e chiude con un reason (feature-libs/quote/components/confirm-dialog/quote-

confirm-dialog.component.ts:L60-L74). Le chiavi i18n del dialog sono costruite dal prefisso configurato: .title, .confirmNote, .a11y.close, opzionali .warningNote e .successMessage (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L365-L390).

Seller edit — attivo solo se stato SELLER_REQUEST/SELLER_DRAFT e isEditable (feature-libs/quote/components/summary/seller-edit/quote-summary-seller-edit.component.service.ts:L133-L140). Lo sconto viene sempre inviato come PERCENT; la scadenza passa da un Subject con debounceTime(updateDebounceTime.expiryDate ?? 500) prima di editQuote (feature-libs/quote/components/summary/seller-edit/quote-summary-seller-edit.component.ts:L129-L184). La data viene composta con ora locale e offset di fuso (feature-libs/quote/components/summary/seller-edit/quote-summary-seller-edit.component.service.ts:L108-L115). La validazione rifiuta >100 o troppi decimali (feature-libs/quote/components/summary/seller-edit/quote-summary-seller-edit.component.service.ts:L234-L256).

Header — il buyer modifica nome/descrizione solo se isEditable e stato BUYER_DRAFT/BUYER_OFFER (feature-libs/quote/components/header/overview/quote-header-overview.component.ts:L89-L95); la label totale è "Total" se tra le azioni c'è CHECKOUT, altrimenti "Estimated total" (feature-libs/quote/components/header/overview/quote-header-overview.component.ts:L304-L311).

Items — QuoteItemsComponentService.retrieveQuoteEntries sceglie la fonte: le entry della quote (nessun cartId), il carrello read-only (con cartId, non editabile) o il carrello attivo editabile (feature-libs/quote/components/items/quote-items.component.service.ts:L80-L91); nel secondo caso il cart viene caricato con extraData: { active: false } (feature-libs/quote/components/items/quote-items.component.service.ts:L130-L138). Il rendering riusa l'outlet CART_ITEM_LIST di cart base con readonly nel contesto (feature-libs/quote/components/items/quote-items.component.html:L27-L30).

Lista — QuoteListModule mappa AccountMyQuotesComponent e fornisce view.defaultPageSize: 5 come default config (feature-libs/quote/components/list/quote-list.module.ts:L35-L49); sort di default byCode con opzioni hard-coded sostituite da data.sorts quando presenti (feature-libs/quote/components/list/quote-list-component.service.ts:L17-L44).

Link e commenti — QuoteLinksComponent forza il reload all'init perché la pagina dettagli è in cache (feature-libs/quote/components/links/quote-links.component.ts:L47-L50); scarica il primo allegato come <filename>.pdf (feature-libs/quote/components/links/quote-links.component.ts:L68-L83); mostra il link all'ordine solo con orderConfig.showOrderQuoteLink e sapOrderCode (feature-libs/quote/components/links/quote-links.component.html:L38-L46). QuoteCommentsComponent.onSend invia, resetta il form comunque e ricarica in successo (feature-libs/quote/components/comments/quote-comments.component.ts:L62-L86).

3.9 Quote: OCC

Dieci endpoint di default; getQuote chiede FULL,expirationTime, i prezzi formattati e entries(FULL) (feature-libs/quote/occ/config/default-occ-quote-config.ts:L9-L31), fusi in OccEndpoints via module augmentation (feature-libs/quote/occ/model/occ-quote-endpoints.model.ts:L61-L63). Con orderConfig.showOrderQuoteLink (default false, feature-libs/order/root/config/default-order-config.ts:L27-L27) l'adapter fonde i field di getQuote e getOrderCode con OccFieldsService.getOptimalUrlGroups (feature-libs/quote/occ/adapters/occ-quote.adapter.ts:L107-L124). editQuote è PATCH, performQuoteAction POST con { action } (feature-libs/quote/occ/adapters/occ-quote.adapter.ts:L136-L167); il download usa responseType: 'blob' as 'json' (feature-libs/quote/occ/adapters/occ-quote.adapter.ts:L253-L264); tutte le chiamate normalizzano gli errori con tryNormalizeHttpError (feature-libs/quote/occ/adapters/occ-quote.adapter.ts:L276-L284).

3.10 Customer ticketing

Root. Sei componenti CMS sulla feature `customerTicketing`; `customerTicketingCore` è un alias della stessa feature ("by default core is bundled together with components") (feature-libs/customer-ticketing/root/customer-ticketing-root.module.ts:L24-L43). Il root importa `CustomerTicketingEventModule` e definisce due ng-route `path: null` per `supportTicketDetails` e `supportTickets` (feature-libs/customer-ticketing/root/customer-ticketing-root.module.ts:L44-L74), mappate su `my-account/support-tickets` e `my-account/support-ticket/:ticketCode` (feature-libs/customer-ticketing/root/config/default-customer-ticketing-routing-config.ts:L9-L21). Nell'app demo il chunk lazy è un wrapper che aggiunge `CdpCustomerTicketingModule` se `environment.cdp` (projects/storefrontapp/src/app/spartacus/features/customer-ticketing/customer-ticketing-wrapper.module.ts:L13-L22).

Modello. Stati `OPEN`, `CLOSED`, `INPROCESS` (feature-libs/customer-ticketing/root/model/customer-ticketing.model.ts:L14-L24); `TicketDetails` porta `availableStatusTransitions` e `ticketEvents`, `TicketEvent` porta `toStatus`, `addedByAgent`, `ticketEventAttachments` (feature-libs/customer-ticketing/root/model/customer-ticketing.model.ts:L26-L69). Tre `LAUNCH_CALLER` aggiunti a runtime (feature-libs/customer-ticketing/root/model/augmented-core.model.ts:L9-L21).

Facade e servizio. `CustomerTicketingFacade` è lazy con 12 metodi (feature-libs/customer-ticketing/root/facade/customer-ticketing.facade.ts:L19-L40). I command di `CustomerTicketingService` usano `CommandStrategy.Queue` (feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L100-L102), cioè `concatMap`: i comandi si accodano (core-libs/core/src/util/command-query/command.service.ts:L105-L116). Le precondizioni prendono `userId` e `ticketCode` dalla route con `take(1)` e lanciano un errore se manca l'utente (feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L254-L270).

Orchestrazione a eventi. Il servizio non ricarica direttamente: dispatcha eventi di dominio e un listener eager li traduce.

- `createTicketCommand` → POST → `TicketCreatedEvent` (feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L86-L103).
- `createTicketEventCommand`: `toStatus` CLOSED → `TicketClosedEvent`; altrimenti, se non c'è allegato, OPEN/INPROCESS → `TicketReopenedEvent`, altro → `NewMessageEvent` (feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L118-L130).
- `uploadAttachmentCommand` usa `payload.ticketId ?? ticketId` e dispatcha `UploadAttachmentSuccessEvent` (feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L151-L163).
- Listener: `TicketCreatedEvent` → messaggio + reload lista (feature-libs/customer-ticketing/root/events/customer-ticketing-event.listener.ts:L50-L62); lingua/valuta → reload lista e dettaglio; login/logout → reset delle quattro query (feature-libs/customer-ticketing/root/events/customer-ticketing-event.listener.ts:L64-L91); Closed → reset ticket + `requestClosed`; Reopened → reload + `requestReopened`; NewMessage/UploadAttachmentSuccess → reload ticket (feature-libs/customer-ticketing/root/events/customer-ticketing-event.listener.ts:L93-L135).

Error handler e SEO. Il core lazy registra `NotFoundTicketRequestHandler` e `CustomerTicketingPageMetaResolver` (feature-libs/customer-ticketing/core/customer-ticketing-core.module.ts:L14-L31). L'handler fa match solo per 404 sulla route `supportTicketDetails` con errori notFound e reindirizza a `supportTickets` (feature-libs/customer-ticketing/core/http-interceptors/handlers/not-found-ticket-request.handler.ts:L38-L70); `isNotFoundError` richiede sia `reason` sia `type` NOT_FOUND (feature-libs/customer-ticketing/core/utils/utils.ts:L16-L21). Il resolver (pageUid `support-ticket-details`) usa il `subject` come heading e aggiunge un breadcrumb "customer service" (feature-libs/customer-ticketing/core/services/customer-ticketing-page-meta.resolver.ts:L53-L101). Per i page meta resolver in generale vedi 40 — SEO e PWA.

OCC. `getTicket` inverte in place `ticketEvents` prima della normalizzazione (`feature-libs/customer-ticketing/occ/adapters/occ-customer-ticketing.adapter.ts:L92-L101`); l'upload è un `FormData` con campo `ticketEventAttachment` (`feature-libs/customer-ticketing/occ/adapters/occ-customer-ticketing.adapter.ts:L212-L219`); associated objects e categorie vengono estratti dai wrapper e normalizzati con `pipeableMany` (`feature-libs/customer-ticketing/occ/adapters/occ-customer-ticketing.adapter.ts:L58-L85`). Alcuni endpoint hanno lo slash iniziale (`/ticketCategories`, `/users/...`) (`feature-libs/customer-ticketing/occ/config/default-occ-customer-ticketing-config.ts:L13-L23`): è innocuo perché `buildUrl` compone con `urlPathJoin`, che ripulisce gli slash di ogni parte (`core-libs/core/src/occ/services/occ-endpoints.service.ts:L233-L238`, `core-libs/core/src/occ/utils/occ-url-util.ts:L12-L33`).

Componenti. I tre dialog (REOPEN, CLOSE, CREATE) sono `inline` di tipo DIALOG (`feature-libs/customer-ticketing/components/shared/customer-ticketing-dialog/default-customer-ticketing-form-layout.config.ts:L12-L32`) e derivano da `CustomerTicketingDialogComponent`, una `@Directive()` astratta che chiude al click sull'host e costruisce il form con validatori dell'allegato (`feature-libs/customer-ticketing/components/shared/customer-ticketing-dialog/customer-ticketing-dialog.component.ts:L82-L118`). "Close" è abilitato con stato OPEN/INPROCESS e transizione verso CLOSED (`feature-libs/customer-ticketing/components/details/customer-ticketing-close/customer-ticketing-close-component.service.ts:L17-L30`); "Reopen" con stato CLOSED e transizione verso INPROCESS/OPEN (`feature-libs/customer-ticketing/components/details/customer-ticketing-reopen/customer-ticketing-reopen-component.service.ts:L17-L31`). Il reopen invia `toStatus INPROCESS` e, se c'è un file, passa `containsAttachment=true` e carica l'allegato sull'evento creato (`feature-libs/customer-ticketing/components/details/customer-ticketing-reopen/customer-ticketing-reopen-dialog/customer-ticketing-reopen-dialog.component.ts:L58-L98`). Il create dialog carica l'allegato sul primo evento del ticket, passando `response.id` esplicitamente (`feature-libs/customer-ticketing/components/list/customer-ticketing-create/customer-ticketing-create-dialog/customer-ticketing-create-dialog.component.ts:L161-L172`). Il dettaglio dispatcha `GetTicketQueryReloadEvent` se il ticket in cache non corrisponde al `ticketCode` della route (`feature-libs/customer-ticketing/components/details/customer-ticketing-details/customer-ticketing-details.component.ts:L83-L97`).

3.11 Subscription billing

Root eager con outlet. Cinque componenti CMS sulla feature `subscriptionBilling` e alias `subscriptionBillingCore` (`feature-libs/subscription-billing/root/subscription-billing-root.module.ts:L24-L40`). Il root fornisce inoltre due outlet del carrello in posizione `AFTER`: `SUBSCRIPTION_PRICE_HEADING` e `SUBSCRIPTION_PRICE_BODY` (`feature-libs/subscription-billing/root/subscription-billing-root.module.ts:L42-L59`), i cui id sono definiti in cart base (`feature-libs/cart/base/root/models/cart-outlets.model.ts:L28-L29`) e resi dalla cart item list (`feature-libs/cart/base/components/cart-shared/cart-item-list/cart-item-list.component.html:L14-L14`). I componenti outlet sono standalone e leggono il contesto con `toSignal(OutletContextData.context$)` (`feature-libs/subscription-billing/root/components/cart/price-heading/subscription-cart-price-heading.component.ts:L22-L31`). I componenti outlet esistono quindi anche senza il chunk lazy. Il prezzo compare però solo se le entry del carrello contengono `sapSubscriptionTerm` e `sapPricePlan` (`feature-libs/subscription-billing/root/services/subscription-product.service.ts:L18-L20`), che i field di default dell'endpoint `cart` non richiedono esplicitamente (`feature-libs/cart/base/occ/config/default-occ-cart-config-factory.ts:L17-L17`); la config OCC di subscription-billing arriva solo dal modulo OCC lazy (`feature-libs/subscription-billing/occ/subscription-billing-occ.module.ts:L23-L23`). `DA VERIFICARE`: dipende dal livello `DEFAULT` del backend.

Prodotti subscription. Un prodotto è subscription se ha sia `sapSubscriptionTerm` sia `sapPricePlan`; i dati si caricano con lo scope `SUBSCRIPTION` (`feature-libs/subscription-billing/root/services/subscription-product.service.ts:L18-L28`). Il model augmenta `Product` e aggiunge `ProductScope.SUBSCRIPTION = 'subscription'` anche a runtime (`feature-libs/subscription-billing/root/model/subscription-product.`

model.ts:L98-L110); l'endpoint product.subscription chiede fields=sapPricePlan,sapSubscriptionTerm (feature-libs/subscription-billing/occ/config/default-occ-subscription-billing-config.ts:L10-L43). Gli scope prodotto sono trattati in 24 — Product e search.

Facade. Tre facade lazy: SubscriptionFacade, SubscriptionBillingFacade, SubscriptionActionsFacade (6 metodi) (feature-libs/subscription-billing/root/facade/subscription-actions.facade.ts:L17-L32). Il core registra tre coppie facade/servizio e due PageMetaResolver (feature-libs/subscription-billing/core/facade/facade-provider.ts:L20-L46).

Codice dall'URL. Il codice della subscription è estratto con la regex /subscription/<id> dall'URL, non dai parametri di route (feature-libs/subscription-billing/core/facade/subscription.service.ts:L126-L134); idem per i bill con /subscription-bill/<id> (feature-libs/subscription-billing/core/facade/subscription-billing.service.ts:L157-L165). Le precondizioni del dettaglio non hanno take(1) e lanciano se manca codice o utente (feature-libs/subscription-billing/core/facade/subscription.service.ts:L111-L123); la query ha solo reloadOn (il resetOn è commentato) (feature-libs/subscription-billing/core/facade/subscription.service.ts:L53-L56).

Azioni senza Command. SubscriptionActionsService restituisce Observable freddi (combineLatest + take(1) + switchMap) (feature-libs/subscription-billing/core/facade/subscription-actions.service.ts:L55-L77): senza subscribe non parte nulla. getExtensionEffectiveDate è l'unico senza take(1) (feature-libs/subscription-billing/core/facade/subscription-actions.service.ts:L123-L138). Né lui né extendSubscription controllano userId/codice (feature-libs/subscription-billing/core/facade/subscription-actions.service.ts:L145-L157); gli altri quattro metodi lanciano un errore se mancano (feature-libs/subscription-billing/core/facade/subscription-actions.service.ts:L35-L121).

OCC. Gli adapter non usano converter: restituiscono il JSON tipizzato normalizzando solo gli errori (feature-libs/subscription-billing/occ/adapters/occ-subscription.adapter.ts:L36-L40). L'estensione invia { numberOfBillingCycles, unlimited } (feature-libs/subscription-billing/occ/adapters/occ-subscription-actions.adapter.ts:L120-L153); reverseCancellation fa POST con body null e Content-Type JSON (feature-libs/subscription-billing/occ/adapters/occ-subscription-actions.adapter.ts:L98-L101); il filtro bill va nel query param filters (feature-libs/subscription-billing/occ/adapters/occ-subscription-billing.adapter.ts:L37-L47).

Componenti. SubscriptionDetailsComponent forza il reload all'init e apre il dialog con openDialogAndSubscribe(SUBSCRIPTION_ACTION_CONFIRMATION, ...) passando subscription, code e mode (feature-libs/subscription-billing/components/details/subscription-details.component.ts:L51-L73); il dialog è inlineRoot (feature-libs/subscription-billing/components/actions-modal/subscription-actions-popup.config.ts:L12-L20). SubscriptionActionsModalComponent usa signals (mode default 'cancel', feature-libs/subscription-billing/components/actions-modal/subscription-actions-modal.component.ts:L67-L92), un effect che in modalità cancel richiede subito la data effettiva (feature-libs/subscription-billing/components/actions-modal/subscription-actions-modal.component.ts:L120-L140) e una mappa di handler per mode in onConfirm (feature-libs/subscription-billing/components/actions-modal/subscription-actions-modal.component.ts:L174-L254). Successo: close + GetSubscriptionByCodeReloadEvent + conferma; errore: close('error') + subscriptionActions.unknownError (feature-libs/subscription-billing/components/actions-modal/subscription-actions-modal-component.service.ts:L23-L59). La lista bill riceve il range date dal dialogClose del DateRangeModalComponent (feature-libs/subscription-billing/components/list/billing/subscription-billing-list.component.ts:L77-L90, feature-libs/subscription-billing/components/list/billing/date-range-modal/date-range-modal.component.ts:L85-L94) e lo serializza come startAt:%s:endAt:%s (feature-libs/subscription-billing/components/list/billing/subscription-billing-list.component.ts:L64-L64).

3.12 Installazione via schematics, costanti e stili

`addQuoteFeatures()` valida l'installazione, risolve le dipendenze tra feature ed esegue in catena `analyzeApplication`, `addFeatures`, `addPackageJsonDependenciesForLibrary(peerDependencies, ...)` e `finalizeInstallation` (feature-libs/quote/schematics/add-quote/index.ts:L25-L43), registrata come `ng-add` e `add` (feature-libs/quote/schematics/collection.json:L4-L16). Lo spec controlla con snapshot che il modulo di configurazione riceva le feature b2b (feature-libs/quote/schematics/add-quote/index_spec.ts:L115-L122), coerente con la config schematics della quote. Le costanti di feature-libs/quote/schematics/constants.ts:L9-L17 replicano nomi già definiti in core-libs (core-libs/schematics/src/shared/lib-configs/quote-schematics-config.ts:L21-L33, core-libs/schematics/src/shared/libs-constants.ts:L237-L238), e nessun file di `feature-libs/quote` le importa: la fonte effettiva è quella di core-libs.

Negli stili quote, il page template usa variabili chiamate `$page-template-allowlist-store-finder` / `$page-template-blocklist-store-finder` pur riferendosi a `QuoteDetailsPageTemplate` (feature-libs/quote/styles/layout/_index.scss:L5-L17): per escludere il template va sovrascritta la variabile con suffisso `-store-finder`. Il mixin `visible-focus` è definito localmente nell'entry SCSS prima di importare gli stili (feature-libs/quote/_index.scss:L4-L12). Le tre `vitest.config.ts` hanno la stessa struttura (jsdom, pool `forks`, coverage v8 con soglie 85/85/65/85) e differiscono solo negli alias (feature-libs/quote/vitest.config.ts:L16-L21, feature-libs/customer-ticketing/vitest.config.ts:L16-L20, feature-libs/subscription-billing/vitest.config.ts:L11-L23).

5. Estratti di codice reale

5.1 Facade proxy con metodi mancanti

feature-libs/quote/root/facade/quote.facade.ts:L21-L38

```ts
@Injectable({
  providedIn: 'root',
  useFactory: () =>
    facadeFactory({
      facade: QuoteFacade,
      feature: QUOTE_FEATURE,
      methods: [
        'getQuotesState',
        'getQuoteDetailsQueryState',
        'getQuoteDetails',
        'createQuote',
        'editQuote',
        'performQuoteAction',
        'addQuoteComment',
        'addDiscount',
      ],
    }),
})
```

core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L119-L123

```ts
    const result: any = new (class extends (facade as any) {})();
    (methods ?? []).forEach((method) => {
      result[method] = (...args: any[]) =>
        this.call(resolver$, method as string, args);
    });
```

5.2 Normalizer delle azioni

feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L30-L44

```ts
    if (source.allowedActions && source.state) {
      target.allowedActions = this.getOrderedActions(
        source.state,
        source.allowedActions,
        source.code
      ).map((action) => this.getActionCategory(action));
```

```
}
const switchToEditModeRequired = target.allowedActions?.find(
  (quoteAction) => quoteAction.type === QuoteActionType.EDIT
);

target.isEditable =
  !!source.allowedActions?.includes(QuoteActionType.EDIT) &&
  !switchToEditModeRequired;
```

feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L60-L89

```ts
const order =
  this.quoteCoreConfig.quote?.actions?.actionsOrderByState?.[state];
if (order) {
  //deep copy order list
  const clonedActionList = structuredClone(order);
  combineLatest([
    this.quoteCartService.isQuoteCartActive(),
    this.quoteCartService.getQuoteId(),
  ])
    .pipe(take(1))
    .subscribe(([isQuoteCartActive, cartQuoteId]) => {
      if (
        state !== QuoteState.BUYER_OFFER &&
        isQuoteCartActive &&
        cartQuoteId === quoteId
      ) {
        const editIndex = clonedActionList.indexOf(QuoteActionType.EDIT);
        if (editIndex > -1) {
          clonedActionList.splice(editIndex, 1);
        }
      }
    });
  return list
    .filter((item) => clonedActionList.includes(item))
    .sort(
      (a, b) => clonedActionList.indexOf(a) - clonedActionList.indexOf(b)
    );
} else {
  return list;
}
```

5.3 Diramazione delle azioni in `QuoteService`

feature-libs/quote/core/facade/quote.service.ts:L245-L266

```ts
      if (
        payload.quoteAction === QuoteActionType.SUBMIT ||
        payload.quoteAction === QuoteActionType.CANCEL
      ) {
        this.cartUtilsService.handleCartAndGoToQuoteList(
          payload.quote.isEditable
        );
        this.isActionPerforming$.next(false);
      }
      if (
        payload.quoteAction === QuoteActionType.REJECT ||
        payload.quoteAction === QuoteActionType.APPROVE
      ) {
        this.routingService.go({ cxRoute: 'quotes' });
      }
      if (
        payload.quoteAction === QuoteActionType.EDIT ||
        payload.quoteAction === QuoteActionType.CHECKOUT
      ) {
        this.saveActiveCart();
        //no cartId present: ensure that we re-fetch quote cart id from quote
        const cartId = payload.quote.cartId;
```

feature-libs/quote/core/facade/quote.service.ts:L337-L354

```ts
  this.activeCartFacade
    .getActive()
    .pipe(
      filter((cart) => cart.code === cartId),
      take(1)
    )
    .subscribe(() => {
      this.triggerReloadAndCompleteAction();
      if (actionType === QuoteActionType.CHECKOUT) {
        this.quoteCartService.setCheckoutAllowed(true);
        this.routingService.go({ cxRoute: 'checkout' });
      } else if (actionType === QuoteActionType.REQUOTE) {
        this.routingService.go({
          cxRoute: 'quoteDetails',
          params: { quoteId: quoteId },
        });
      }
    });
```

5.4 Query dei dettagli guidata dal router

feature-libs/quote/core/facade/quote.service.ts:L396-L420

```ts
            combineLatest([
              this.routingService.getRouterState(),
              this.authService.isUserLoggedIn(),
            ]).pipe(
              //we don't need to cover the intermediate router states where a future route is already known.
              //only changes to the URL are relevant. Otherwise we get unneeded hits when e.g. navigating back from quotes.
              //In addition we check is the user is logged in as otherwise we would get (failing) calls after logout
              filter(
                ([routerState, isLoggedIn]) =>
                  routerState.nextState === undefined && isLoggedIn
              ),
              withLatestFrom(this.userIdService.takeUserId()),
              switchMap((([routerState, _isLoggedIn], userId]) => {
                return this.quoteConnector.getQuote(
                  userId,
                  routerState.state.params.quoteId
                );
              })
            )
          )
        ),

      {
        reloadOn: [QuoteDetailsReloadQueryEvent, LoginEvent],
      }
```

5.5 Guard del quote cart

feature-libs/quote/components/cart-guard/quote-cart.guard.ts:L67-L80

```ts
  protected checkAllowedCheckoutNavigation(
    routerState: RouterState,
    isCheckoutAllowed: boolean
  ) {
    const nextStateIsCheckout =
      routerState.nextState?.semanticRoute?.startsWith('checkout');
    const currentStateIsCheckout =
      routerState.state.semanticRoute?.startsWith('checkout');
    const noNextState = routerState.nextState === undefined;
    return (
      (nextStateIsCheckout || (currentStateIsCheckout && noNextState)) &&
      isCheckoutAllowed
    );
  }
```

5.6 Ricerca del dialog di conferma

feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L349-L363

```ts
protected isConfirmationDialogRequired(
  action: QuoteActionType,
  state: QuoteState,
  cartIsEmptyOrQuoteCart: boolean
): boolean {
  const mappingConfig = this.quoteUIConfig.quote?.confirmActionDialogMapping;
  const dialogConfig =
    mappingConfig?.[state]?.[action] ??
    mappingConfig?.[this.stateToRoleTypeForDialogConfig(state)]?.[action] ??
    mappingConfig?.[QuoteRoleType.ALL]?.[action];
  return (
    !!dialogConfig &&
    (!cartIsEmptyOrQuoteCart || !dialogConfig.showOnlyWhenCartIsNotEmpty)
  );
}
```

5.7 Ticketing: evento scelto in base a `toStatus`

feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L115-L132

```ts
        this.customerTicketingConnector
          .createTicketEvent(customerId, ticketId, payload.ticketEvent)
          .pipe(
            tap(() => {
              if (payload.ticketEvent.toStatus?.id === STATUS.CLOSED) {
                this.eventService.dispatch({}, TicketClosedEvent);
              } else if (!payload.containsAttachment) {
                if (
                  payload.ticketEvent.toStatus?.id === STATUS.OPEN ||
                  payload.ticketEvent.toStatus?.id === STATUS.INPROCESS
                ) {
                  this.eventService.dispatch({}, TicketReopenedEvent);
                } else {
                  this.eventService.dispatch({}, NewMessageEvent);
                }
              }
            })
          )
```

5.8 Subscription: outlet eager e azioni fredde

feature-libs/subscription-billing/root/subscription-billing-root.module.ts:L47-L56

```ts
    provideOutlet({
      id: CartOutlets.SUBSCRIPTION_PRICE_HEADING,
      position: OutletPosition.AFTER,
      component: SubscriptionCartPriceHeadingComponent,
    }),
    provideOutlet({
      id: CartOutlets.SUBSCRIPTION_PRICE_BODY,
      position: OutletPosition.AFTER,
      component: SubscriptionCartPriceBodyComponent,
    }),
```

feature-libs/subscription-billing/core/facade/subscription-actions.service.ts:L55-L77

```ts
  cancelSubscription(
    cancellationDetails: SubscriptionCancellationDetails,
    subscriptionCode?: string
  ): Observable<unknown> {
    return combineLatest([
      this.userIdService.getUserId(),
      of(subscriptionCode),
    ]).pipe(
      take(1),
      switchMap(([userId, code]) => {
        if (!userId || !code) {
          throw new Error(
            'Cannot cancel subscription: missing user ID or subscription code.'
          );
        }
        return this.subscriptionActionsConnector.cancelSubscription(
          userId,
          code,
          cancellationDetails
        );
      })
    );
  }
```

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
routing.routes.quotes / quoteDetails	RoutingConfig	my-account/quotes, my-account/quote/:quoteId	feature-libs/quote/root/quote-root.module.ts:L66-L78	navigazioni cxRoute (es. feature-libs/quote/core/facade/quote.service.ts:L252-L259)

QuoteConfig (in root) è un'interfaccia vuota agganciata a Config.quote (feature-libs/quote/root/config/quote.config.ts:L9-L15); le chiavi concrete arrivano da QuoteCoreConfig (feature-libs/quote/core/config/quote-core.config.ts:L11-L29) e QuoteUIConfig (feature-libs/quote/components/config/quote-ui.config.ts:L15-L24). Il mapping dei dialog è indicizzato per stato **o** per ruolo; vince sempre quello per stato (feature-libs/quote/components/config/quote-ui.config.ts:L34-L45).

Nota sui default forniti dai chunk lazy (es. view.defaultPageSize o defaultQuoteCoreConfig): ConfigurationService raccoglie via UnifiedInjector i DefaultConfigChunk/ConfigChunk dei moduli caricati, li fonde con priorità default < ambient default < ambient < root e, salvo il toggle disableConfigUpdates, li fonde anche nel Config globale (core-libs/core/src/config/services/configuration.service.ts:L76-L106). Una provideConfig dell'app vince quindi sempre sui default lazy. Dettagli in 11 — Configurazione.

customerTicketing.inputCharactersLimitForSubject	number	255	feature-libs/customer-ticketing/root/config/default-customer-ticketing-config.ts:L34-L34	feature-libs/customer-ticketing/components/shared/customer-ticketing-dialog/customer-ticketing-dialog.component.ts:L68-L73
customerTicketing.listViewPageSize	number	5	feature-libs/customer-ticketing/root/config/default-customer-ticketing-config.ts:L35-L35	feature-libs/customer-ticketing/components/list/customer-ticketing-list/customer-ticketing-list.component.ts:L62-L63

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
`customerTicketing.agentSessionTimer.startingDelayInSeconds`	number	nessuno	`feature-libs/customer-ticketing/root/config/customer-ticketing-config.ts:L16-L18`	mai letta nella lib
`backend.occ.endpoints.getTicket` ecc.	string	v. §3.10	`feature-libs/customer-ticketing/occ/config/default-occ-customer-ticketing-config.ts:L9-L27`	`feature-libs/customer-ticketing/occ/adapters/occ-customer-ticketing.adapter.ts:L104-L111`
`routing.routes.supportTickets` / `supportTicketDetails`	`RoutingConfig`	`my-account/support-tickets`, `my-account/support-ticket/:ticketCode`	`feature-libs/customer-ticketing/root/config/default-customer-ticketing-routing-config.ts:L9-L21`	handler e dialog

`CustomerTicketingConfig` è una classe astratta con `useExisting: Config` (`feature-libs/customer-ticketing/root/config/customer-ticketing-config.ts:L10-L27`); le costanti di fallback sono in `feature-libs/customer-ticketing/root/customer-ticketing-constants.ts:L7-L12`.

6.3 Subscription billing

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
`Months` / `Years` / `Days` / `Weeks` (top-level `Config`)	number	12 / 5 / 30 / 4 (costante)	`feature-libs/subscription-billing/root/config/default-extend-subscription-dropdown-options-config.ts:L9-L15`	costante importata direttamente: `feature-libs/subscription-billing/components/actions-modal/subscription-actions-modal.component.ts:L84-L85`
`backend.occ.endpoints.product.subscription`	string	`products/${productCode}?fields=sapPricePlan,sapSubscriptionTerm`	`feature-libs/subscription-billing/occ/config/default-occ-subscription-billing-config.ts:L36-L39`	`ProductService.get(..., [ProductScope.SUBSCRIPTION])` in `feature-libs/subscription-billing/root/services/subscription-product.service.ts:L26-L27`
`backend.occ.endpoints.subscription*`	string	10 endpoint	`feature-libs/subscription-billing/occ/config/default-occ-subscription-billing-config.ts:L10-L29`	adapter OCC
`routing.routes.subscriptions` ecc.	`RoutingConfig`	`my-account/subscriptions`, …	`feature-libs/subscription-billing/root/config/default-subscription-billing-routing-config.ts:L11-L26`	componenti

Nell'app demo la feature subscription carica solo l'inglese con `fallbackLang: 'en'` (`projects/storefrontapp/src/app/spartacus/features/subscription-billing/subscription-billing-feature.module.ts:L30-L36`).

7. Commenti e note notevoli dal sorgente

- **Perché** `expirationTime` **è una stringa**: "we cannot use date here, as this would result in a format 2023-08-26T07:13:00.000Z sent to commerce while it expects (for the same time) 2023-08-26T09:13:00+02:00" (`feature-libs/quote/root/model/quote.model.ts:L120-L128`).
- **Filtro del router state** nella query dettagli: "we don't need to cover the intermediate router states where a future route is already known. [...] In addition we check is the user is logged in as otherwise we would get (failing) calls after logout" (`feature-libs/quote/core/facade/quote.service.ts:L400-L402`).
- `reloadOn: []` **nella lista**: "Changes to currentPage$/sort$ are now handled reactively within the factory itself, so reloadOn is no longer needed." (`feature-libs/quote/core/facade/quote.service.ts:L446-L446`).
- **Route** `quotes` **dal CMS**: "The ng route corresponding to the cxRoute 'quotes' is not defined here as it is provided via CMS." (`feature-libs/quote/root/quote-root.module.ts:L88-L93`).
- **Marker component**: "This component is used as a marker. In case it is present in the CMS composition of a page, this page can be navigated to only if the QuoteCartGuard [...] allows it." (`feature-libs/quote/components/cart-guard/quote-cart-guard.component.ts:L10-L17`) e il JSDoc del guard sui due casi di redirect (`feature-libs/quote/components/cart-guard/quote-cart.guard.ts:L19-L24`).
- **Niente** `AuthGuard` **sul request button**: "We cannot enforce that via an authGuard here because otheriwise the entire cart page would need an authenticated user." (`feature-libs/quote/components/request-button/quote-request-button.component.ts:L32-L37`).
- **cartBase sempre caricato** perché `getQuoteDetails()` interroga sempre `activeCartFacade` (`feature-libs/quote/components/items/quote-items.component.ts:L29-L33`).
- **Scenario ASM del 404** (`feature-libs/quote/root/http-interceptors/quote-not-found.handler.ts:L44-L50`).
- **TODO sort hard-coded** per gap API, CXEC-31715 (`feature-libs/quote/components/list/quote-list-component.service.ts:L22-L23`).
- **Deprecazioni**: `isShowDownloadProposalButtonFeatureEnabled` obsoleto dal 2211.41, ritorna sempre `true` (`feature-libs/quote/components/links/quote-links.component.ts:L95-L103`); tre metodi della lista bill spostati in `DateRangeModalComponent` (`feature-libs/subscription-billing/components/list/billing/subscription-billing-list.component.ts:L117-L158`).
- **Altezza fissa 226 px** dei bottoni azione, da tenere allineata con `_quote-summary-actions.scss` (`feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L76-L80`).
- `resetOn` **commentato** nella query subscription, residuo copiato dal ticketing (`feature-libs/subscription-billing/core/facade/subscription.service.ts:L55-L55`).
- **Core bundled con components** per ticketing (`feature-libs/customer-ticketing/root/customer-ticketing-root.module.ts:L38-L39`).
- **Triple-slash reference** ai tipi globali nel `public_api` del ticketing (`feature-libs/customer-ticketing/public_api.ts:L7-L14`).

8. Extension point

EXTENSION POINT	COME	RIFERIMENTO	RICETTA
Ordine e primarietà delle azioni quote	`provideConfig({ quote: { actions: { primaryActions, actionsOrderByState } } })`	`feature-libs/quote/core/config/quote-core.config.ts:L11-L29`	50 — Ricette config/DI

EXTENSION POINT	COME	RIFERIMENTO	RICETTA
Dialog di conferma per stato/ruolo	`quote.confirmActionDialogMapping` (`i18nKeyPrefix`, `showOnlyWhenCartIsNotEmpty`, …)	`feature-libs/quote/components/config/quote-ui.config.ts:L34-L57`	50 — Ricette config/DI
Sostituire la logica della facade	`{ provide: QuoteFacade, useExisting: MyQuoteService }` nel chunk, oppure estendere `QuoteService`	`feature-libs/quote/core/facade/facade-providers.ts:L11-L17`	53 — Ricette feature lazy
Adapter/converter OCC	`QuoteAdapter`, `QUOTE_NORMALIZER` (multi), 5 serializer; ticketing ha 7 token; subscription ha solo adapter (nessun converter)	`feature-libs/quote/core/connectors/converters.ts:L20-L46`, `feature-libs/customer-ticketing/core/connectors/converters.ts:L18-L45`, `feature-libs/subscription-billing/occ/adapters/occ-subscription.adapter.ts:L36-L40`	52 — Ricette OCC
Endpoint	`backend.occ.endpoints.*` (augment di `OccEndpoints`)	`feature-libs/quote/occ/model/occ-quote-endpoints.model.ts:L61-L63`	52 — Ricette OCC
Componenti CMS	sovrascrivere `cmsComponents` (es. `QuoteSummaryComponent`, `SupportTicketDetailsComponent`, `SubscriptionDetailsComponent`)	`feature-libs/quote/components/summary/quote-summary.module.ts:L30-L37`	51 — Ricette CMS/outlet/layout
Guard del quote cart	estendere `QuoteCartGuard` (`checkAllowedCheckoutNavigation` è `protected`) e rimappare `QuoteCartGuardComponent.guards`	`feature-libs/quote/components/cart-guard/quote-cart.guard.ts:L67-L80`	51 — Ricette CMS/outlet/layout
Outlet del carrello per subscription	`provideOutlet` su `CartOutlets.SUBSCRIPTION_PRICE_*` (REPLACE/BEFORE/AFTER)	`feature-libs/subscription-billing/root/subscription-billing-root.module.ts:L47-L56`	51 — Ricette CMS/outlet/layout
Error handler	estendere `QuoteBadRequestHandler`/`QuoteNotFoundHandler`/`NotFoundTicketRequestHandler` (metodi protected) e registrarli come `HttpErrorHandler` multi	`feature-libs/quote/root/quote-root.module.ts:L108-L118`	50 — Ricette config/DI
Eventi di reload	dispatch di `QuoteDetailsReloadQueryEvent`, `GetTicketQueryReloadEvent`, `GetSubscriptionByCodeReloadEvent`; override dei metodi protected `get*QueryReloadEvents` e `get*QueryResetEvents` di `CustomerTicketingService`	`feature-libs/quote/core/event/quote.events.ts:L9-L14`, `feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L57-L84`	50 — Ricette config/DI
Dialog	`LAUNCH_CALLER.QUOTE_ACTION_CONFIRMATION`, `CUSTOMER_TICKETING_*`, `SUBSCRIPTION_ACTION_CONFIRMATION`, `DATE_RANGE_MODAL` con `launch` config	`feature-libs/quote/components/confirm-dialog/default-quote-confirm-dialog.config.ts:L10-L18`	51 — Ricette CMS/outlet/layout
Page meta	`PageMetaResolver` multi (ticket, subscription)	`feature-libs/customer-ticketing/core/customer-ticketing-core.module.ts:L14-L31`	52 — Ricette OCC/meta resolver
Traduzioni	chunk `quote`, `customerTicketing`, `myAccountV2CustomerTicketing`	`feature-libs/quote/assets/translations/translations.ts:L9-L11`, `feature-libs/customer-ticketing/assets/translations/translations.ts:L9-L18`	53 — Ricette traduzioni

Attenzione all'API pubblica: `OccQuoteActionNormalizer` e `OccQuoteEntryNormalizer` non sono esportati da `occ/public_api.ts` (feature-libs/quote/occ/public_api.ts:L7-L9); per estenderli bisogna importare da path interni. `SubscriptionDetailsPageMetaResolver` e `SubscriptionBillingDetailsPageMetaResolver` invece sono pubblici in `@spartacus/subscription-billing/core` (feature-libs/subscription-billing/core/services/index.ts:L6-L7, feature-libs/subscription-billing/core/public_api.ts:L10-L10). Vedi 54 — API pubblica e upgrade.

---

9. Trappole, casi limite, comportamenti controintuitivi

Quote

1. `requote` **e** `downloadAttachment` **non sono proxati.** Fuori dal chunk `quote` (dove `QuoteFacade` è ancora il proxy) chiamarli dà un metodo non definito (feature-libs/quote/root/facade/quote.facade.ts:L27-L36, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L119-L123). Il chunk `request-button` usa sempre il proxy, ma chiama solo `createQuote`, che è proxato (feature-libs/quote/components/request-button/quote-request-button.component.ts:L43-L57).
2. **Il componente ignora l'Observable di** `requote`: funziona solo perché `Command.execute` è eager (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L309-L311, core-libs/core/src/util/command-query/command.service.ts:L126-L131).
3. `isEditable` **significa "OCC permette EDIT ma EDIT non è un bottone"**: è `false` finché `EDIT` è offerta come bottone; tipicamente indica "già in edit", ma è `true` anche per gli stati il cui ordine configurato filtra via `EDIT` (con i default `EXPIRED`, `CANCELLED`) (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L37-L43, feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L82-L83, feature-libs/quote/core/config/default-quote.core.config.ts:L30-L31).
4. **Azioni OCC scartate silenziosamente**: per gli stati con ordine configurato, le azioni non elencate spariscono; per gli altri passano tutte senza ordine (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L82-L89). Se aggiungi un'azione lato backend, aggiungila anche in `actionsOrderByState`.
5. **Lettura sincrona dello stato carrello nel converter**: `take(1)` dentro `subscribe` in `convert`; se il cart non ha ancora emesso, `EDIT` non viene rimosso (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L65-L81). La query dettagli mitiga attendendo una prima emissione del carrello (feature-libs/quote/core/facade/quote.service.ts:L388-L397).
6. `currentPage = 0` **non inviato** (test di truthiness) (feature-libs/quote/occ/adapters/occ-quote.adapter.ts:L59-L61).
7. `view.defaultPageSize: 5` **globale**: fornito come default config da `QuoteListModule` (feature-libs/quote/components/list/quote-list.module.ts:L36-L40); dopo il caricamento del chunk viene fuso nel `Config` globale (salvo `disableConfigUpdates`) e può influenzare altri consumer di `ViewConfig` che non impostano il valore (core-libs/core/src/config/services/configuration.service.ts:L92-L106).
8. **Campo PO incoerente**: `defineQuoteMetaData` invia `sapPurchaseOrderNumber` mentre `QuoteMetadata` dichiara `purchaseOrderNumber` (feature-libs/quote/components/header/overview/quote-header-overview.component.ts:L71-L78, feature-libs/quote/root/model/quote.model.ts:L120-L128).
9. **Proprietà non enumerabili**: il buyer edit usa `Object.defineProperty` senza `enumerable`, per questo il consumer usa `Object.getOwnPropertyNames` (feature-libs/quote/components/header/buyer-edit/quote-header-buyer-edit.component.ts:L65-L78, feature-libs/quote/components/header/overview/quote-header-overview.component.ts:L68-L68).
10. **Validatori che si accumulano**: `fillFormAttributes` chiama `addValidators` a ogni emissione della quote (feature-libs/quote/components/summary/seller-edit/quote-summary-seller-edit.component.ts:L105-

L110).

11. **Sconti ABSOLUTE impostati dal backend** non sono mostrati nel campo; il client invia sempre `PERCENT` (feature-libs/quote/components/summary/seller-edit/quote-summary-seller-edit.component.ts:L112-L121, feature-libs/quote/components/summary/seller-edit/quote-summary-seller-edit.component.ts:L129-L184).
12. **Eccezione con locale senza** `%`: `getLocalizationElements` lancia `No percentage sign present` (feature-libs/quote/components/summary/seller-edit/quote-summary-seller-edit.component.service.ts:L142-L152).
13. **Listener di chiusura dialog**: `handleConfirmationDialogClose` ricrea la subscription a ogni click; una chiusura senza `'yes'` lascia il listener attivo fino al click successivo o al destroy (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L283-L299).
14. **Download proposta**: solo `attachments[0]`, estensione `.pdf` forzata (feature-libs/quote/components/links/quote-links.component.ts:L69-L74).
15. **Dipendenza dal testo backend** `'Quote not found'` (feature-libs/quote/root/http-interceptors/quote-not-found.handler.ts:L54-L54) e dalle regex dei messaggi `IllegalArgumentError` (feature-libs/quote/root/http-interceptors/quote-bad-request.handler.ts:L121-L133): una localizzazione dei messaggi lato backend rompe il matching.
16. **Toggle requote**: con il default core (`false`) `REQUOTE` non viene disabilitato sotto soglia; l'app demo lo attiva (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1110-L1110, projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L394-L394). Vedi 42 — Feature toggle.

Customer ticketing

17. `ticketCode` **letto una volta**: le precondizioni usano `take(1)`; cambiare ticket richiede un reload esplicito, che il dettaglio fa quando il ticket in cache non corrisponde alla route (feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L254-L270, feature-libs/customer-ticketing/components/details/customer-ticketing-details/customer-ticketing-details.component.ts:L83-L97).
18. **Con allegato niente Reopened/NewMessage**: non compare `requestReopened`; il reload arriva solo da `UploadAttachmentSuccessEvent` (feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L121-L130).
19. `reverse()` **in place** sulla risposta di `getTicket` (feature-libs/customer-ticketing/occ/adapters/occ-customer-ticketing.adapter.ts:L99-L99).
20. **Tipo di ritorno di** `createTicket`: tipato `Observable<TicketStarter>` nell'adapter ma consumato come `TicketDetails` (feature-libs/customer-ticketing/core/connectors/customer-ticketing.adapter.ts:L36-L39, feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L325-L329).
21. **Config morta**: `agentSessionTimer` non è letto da nessun file della lib (feature-libs/customer-ticketing/root/config/customer-ticketing-config.ts:L16-L18).
22. `window`/`document` **globali** nel download allegato (non `WindowRef`): eseguibile solo nel browser, dove il click avviene (feature-libs/customer-ticketing/components/details/customer-ticketing-messages/customer-ticketing-messages.component.ts:L77-L86).
23. **Messaggi backend raw**: gli errori `HttpErrorModel` della creazione sono mostrati con `{ raw: err.message }` (feature-libs/customer-ticketing/components/list/customer-ticketing-create/customer-ticketing-create-dialog/customer-ticketing-create-dialog.component.ts:L184-L206).

Subscription billing

24. `productCode` **letto troppo presto**: `SubscriptionProductPriceComponent` usa l'`@Input()` in un field initializer, prima dell'assegnazione degli input, quindi in pratica usa sempre `currentProductService` (feature-libs/

subscription-billing/components/product/price/subscription-product-price.component.ts:L30-L35, feature-libs/subscription-billing/root/services/subscription-product.service.ts:L18-L28).

25. **Config di estensione non personalizzabile**: `ExtendSubscriptionFrequencyDropdownOptionsConfig` augmenta `Config` ma il modal usa la costante `defaultExtendDropdownOptions` (feature-libs/subscription-billing/components/actions-modal/subscription-actions-modal.component.ts:L84-L85, feature-libs/subscription-billing/root/config/extend-subscription-dropdown-options-config.ts:L10-L23).
26. **Precondizioni senza** `take(1)`: navigare fuori da `/subscription/` fa lanciare l'errore delle precondizioni → stato `error` della query (feature-libs/subscription-billing/core/facade/subscription.service.ts:L111-L123).
27. **Azioni fredde**: senza subscribe nessuna richiesta parte (diverso da quote/ticketing con `Command`) (feature-libs/subscription-billing/core/facade/subscription-actions.service.ts:L55-L77); `getExtensionEffectiveDate` senza `take(1)` rifà la POST a ogni cambio di userId (feature-libs/subscription-billing/core/facade/subscription-actions.service.ts:L123-L138).
28. `dialogClose` **globale**: la lista bill si sottoscrive nel costruttore senza unsubscribe e reagisce a qualunque dialog chiuso con un oggetto (feature-libs/subscription-billing/components/list/billing/subscription-billing-list.component.ts:L77-L90).
29. `?fields=FULL` **+ queryParams**: l'endpoint `subscriptionBillsList` contiene già `?fields=FULL`, ma `buildUrl` separa la query dell'endpoint e la unisce ai `queryParams` con `fromString`, quindi non si producono due `?` (feature-libs/subscription-billing/occ/config/default-occ-subscription-billing-config.ts:L10-L43, core-libs/core/src/occ/services/occ-endpoints.service.ts:L125-L146).
30. **Nomi schematics asimmetrici**: `addCustomerTicketingFeatures` (plurale) vs `addSubscriptionBillingFeature` (singolare) (feature-libs/customer-ticketing/schematics/add-customer-ticketing/index.ts:L25-L25, feature-libs/subscription-billing/schematics/add-subscription-billing/index.ts:L25-L25).

---

10. Come fare debug

- **"Il bottone X non compare"**: confronta `allowedActions` nella risposta di rete di `getQuote` con `actionsOrderByState[state]` effettivo (`ConfigurationService.config.quote`); ricorda che EDIT sparisce se il quote cart attivo è proprio quella quote (feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L60-L89). Un breakpoint in `OccQuoteActionNormalizer.convert` mostra input e output.
- **"Il bottone è disabilitato"**: controlla `quote.threshold` e `totalPrice.value` e il toggle per REQUOTE (feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L219-L232).
- **"Vengo rimbalzato sulla pagina della quote"**: è `QuoteCartGuard`. Verifica se il carrello attivo ha `quoteCode` (feature-libs/quote/core/services/quote-cart.service.ts:L18-L45) e il valore di `checkoutAllowed` (diventa `true` solo da `loadQuoteCartAndProceed` per CHECKOUT, feature-libs/quote/core/facade/quote.service.ts:L345-L347). Nello store NgRx del router controlla `nextState.semanticRoute` (feature-libs/quote/components/cart-guard/quote-cart.guard.ts:L67-L80).
- **"La quote non si aggiorna"**: la query dettagli si ricarica solo su `QuoteDetailsReloadQueryEvent` e `LoginEvent` (feature-libs/quote/core/facade/quote.service.ts:L418-L420); osserva `EventService.get(QuoteDetailsReloadQueryEvent)` per capire se l'evento parte (cart listener, link, commenti).
- **Spinner infinito**: `isActionPerforming$` torna a `false` solo nei rami previsti (feature-libs/quote/core/facade/quote.service.ts:L244-L292, feature-libs/quote/core/facade/quote.service.ts:L356-L360); per EDIT/CHECKOUT dipende dall'arrivo del cart atteso in `getActive()`.

- **Messaggi d'errore inattesi**: verifica quale `HttpErrorHandler` vince (priorità `NORMAL` degli handler quote, feature-libs/quote/root/http-interceptors/quote-bad-request.handler.ts:L54-L56) e se il payload OCC corrisponde ai tipi/regex attesi.
- **Ticketing**: per lista o dettaglio "vecchi", segui la catena evento → listener (feature-libs/customer-ticketing/root/events/customer-ticketing-event.listener.ts:L64-L135); un errore "Customer ticketing pre conditions not met" indica utente anonimo (feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L254-L270).
- **Subscription**: se il dettaglio va in errore controlla che l'URL contenga `/subscription/<id>` (regex, feature-libs/subscription-billing/core/facade/subscription.service.ts:L126-L134); se un'azione "non fa nulla", verifica che qualcuno sottoscriva l'Observable restituito dalla facade.
- **Chunk caricati**: nel pannello Network deve comparire il chunk di `@spartacus/quote/components/cart-guard` sulle pagine con il marker, quello di `request-button` sul carrello e quello principale solo quando serve `QuoteService` (projects/storefrontapp/src/app/spartacus/features/quote-feature.module.ts:L26-L63). Vedi anche 12 — Feature module e lazy loading.

---

11. Domande di autoverifica

1. **Perché la lib quote definisce tre nomi feature invece di uno?** Per caricare marker del guard e bottone "Request quote" senza il chunk completo: sono mappati su `quote_cart_guard` e `quote_request`, con `import()` separati. — feature-libs/quote/root/quote-root.module.ts:L46-L64, projects/storefrontapp/src/app/spartacus/features/quote-feature.module.ts:L26-L63
2. **Cosa succede se un componente fuori dal chunk `quote` chiama `quoteFacade.requote(code)`?** Sul proxy `requote` non è definito, perché non è in `methods`; il proxy definisce solo i metodi elencati. — feature-libs/quote/root/facade/quote.facade.ts:L27-L36, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L119-L123
3. **Quando `Quote.isEditable` è `true`?** Quando OCC permette EDIT ma EDIT è stato rimosso dalle azioni visualizzate, tipicamente quando la quote (non in `BUYER_OFFER`) è già nel quote cart attivo, ma anche negli stati il cui ordine configurato non contiene `EDIT` (con i default `EXPIRED` e `CANCELLED`), dove il filtro lo scarta. — feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L37-L43, feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L70-L80, feature-libs/quote/occ/converters/occ-quote-action-normalizer.ts:L82-L83, feature-libs/quote/core/config/default-quote.core.config.ts:L30-L31
4. **Come fa `QuoteCartGuard` a lasciar passare il checkout di una quote?** `loadQuoteCartAndProceed` imposta `setCheckoutAllowed(true)` prima di navigare; il guard consente se la prossima route semantica inizia con `checkout` (o si è già in checkout senza nextState) e il checkout è consentito. — feature-libs/quote/core/facade/quote.service.ts:L345-L347, feature-libs/quote/components/cart-guard/quote-cart.guard.ts:L67-L80
5. **In che ordine viene cercato il config del dialog di conferma?** Stato → ruolo derivato dal prefisso dello stato → `ALL`; serve il dialog se il config esiste e il carrello non è vuoto/quote cart oppure `showOnlyWhenCartIsNotEmpty` è falso. — feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L349-L363, feature-libs/quote/components/summary/actions/quote-summary-actions.component.ts:L411-L419
6. **Perché entrare in modalità EDIT non fa perdere il carrello normale?** `saveActiveCart` salva come saved cart il carrello attivo non vuoto e non quote cart prima di caricare il quote cart. — feature-libs/quote/core/facade/quote.service.ts:L461-L487

7. **Perché dopo aver aggiunto un prodotto al quote cart i totali della quote si aggiornano?** `QuoteCartEventListener` trasforma gli eventi di successo del carrello in `QuoteDetailsReloadQueryEvent`, che è nel `reloadOn` della query dettagli. — `feature-libs/quote/core/event/quote-cart-event.listener.ts:L29-L49`, `feature-libs/quote/core/facade/quote.service.ts:L418-L420`
8. **Che differenza c'è tra le strategie dei command quote e ticketing?** Quote usa `CancelPrevious` (`switchMap`, il comando nuovo cancella il precedente); ticketing usa `Queue` (`concatMap`, i comandi si accodano). — `feature-libs/quote/core/facade/quote.service.ts:L127-L129`, `feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L100-L102`, `core-libs/core/src/util/command-query/command.service.ts:L73-L116`
9. **Quale evento parte quando si riapre un ticket con un allegato?** Nessun `TicketReopenedEvent`: con `containsAttachment` il servizio non dispatcha Reopened/NewMessage; il reload arriva da `UploadAttachmentSuccessEvent`. — `feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L118-L130`, `feature-libs/customer-ticketing/core/facade/customer-ticketing.service.ts:L151-L163`
10. **Perché i componenti del prezzo di abbonamento in carrello esistono anche se il chunk `subscriptionBilling` non è stato caricato, e perché `cancelSubscription()` senza subscribe non fa nulla?** Gli outlet `SUBSCRIPTION_PRICE_*` sono forniti dal root module eager con componenti standalone (il prezzo appare però solo se le entry hanno `sapSubscriptionTerm`/`sapPricePlan`: `DA VERIFICARE`, dipende dal livello `DEFAULT` del backend); le azioni di `SubscriptionActionsService` sono Observable freddi, non `Command`. — `feature-libs/subscription-billing/root/subscription-billing-root.module.ts:L42-L59`, `feature-libs/subscription-billing/core/facade/subscription-actions.service.ts:L55-L77`

Prerequisiti consigliati: 12 — Feature module e lazy loading, 17 — Outlet, 19 — State management, 20 — Facade, command & query, eventi, 21 — Livello OCC. Collegati: 25 — Carrello, 26 — Checkout, 27 — Ordini, 11 — Configurazione, 41 — Errori e global message.

1. A cosa serve e perché esiste

Questo capitolo raccoglie quattro feature library che hanno in comune il tema "dove e quando arriva la merce":

LIBRERIA	PACCHETTO	COSA FA	STATO
`requested-delivery-date` (RDD)	`@spartacus/requested-delivery-date`	Permette di scegliere una data di consegna richiesta durante il checkout (step delivery mode) e la mostra nel riepilogo ordine	nessun NgRx, facade lazy + chiamata OCC diretta
`estimated-delivery-date` (EDD)	`@spartacus/estimated-delivery-date`	Mostra la data stimata di arrivo (arrival slots) sulle righe del carrello / ordine	nessun NgRx, solo un componente + un override degli endpoint carrello
`storefinder`	`@spartacus/storefinder`	Pagina "trova negozio": ricerca testuale o per geolocalizzazione, conteggi per paese/regione, dettaglio negozio, mappa Google	NgRx (`stores`) + facade lazy
`pickup-in-store`	`@spartacus/pickup-in-store`	"Ritiro in negozio" (BOPIS): scelta del negozio dal PDP e dal carrello, stock per negozio, negozio preferito, riepiloghi in checkout/conferma	NgRx (3 feature) + 4 facade lazy

Le quattro librerie seguono lo schema classico delle feature lib descritto nel capitolo 12: un entry point `root` caricato eager (nomi feature, config CMS lazy, outlet, facade astratte, modelli augmentati) e un modulo "pesante" (core + occ + componenti) caricato on demand.

Il tratto comune più interessante è che **nessuna delle quattro modifica il codice del carrello o del checkout**: si agganciano tramite *outlet* esposti da cart/checkout/order (`CartOutlets.DELIVERY_MODE`, `CartOutlets.ORDER_OVERVIEW`, `CartOutlets.ITEM_DETAILS`, `CartOutlets.ITEM_DELIVERY_DETAILS`, `CartOutlets.ADD_TO_CART_PICKUP_OPTION`, …) (feature-libs/cart/base/root/models/cart-outlets.model.ts:L10-L31), tramite *module augmentation* dei modelli (`Cart`, `Order`, `OrderEntry`, `Consignment`) e tramite *override di configurazione* (endpoint OCC, dipendenze tra feature). Sono quindi un ottimo catalogo di tecniche di estensione "non invasive", e allo stesso tempo contengono parecchi casi limite che vale la pena conoscere (sezione 9).

In sintesi:

- **RDD**: un componente in outlet AFTER sul delivery mode del checkout chiama `RequestedDeliveryDateFacade.setRequestedDeliveryDate` → `PUT users/${userId}/carts/${cartId}/requestedretrievaldate?requestedRetrievalAt=…` (feature-libs/requested-delivery-date/root/requested-delivery-date-root.module.ts:L35-L50, feature-libs/requested-delivery-date/occ/config/default-occ-requested-delivery-date-config.ts:L9-L18).
- **EDD**: un componente in outlet AFTER su `CartOutlets.ITEM_DETAILS` legge `arrivalSlots` dall'entry; perché il backend li restituisca, la lib ridefinisce gli endpoint `carts`/`cart`/`createCart` aggiungendo `arrivalSlots` ai `fields` (feature-libs/estimated-delivery-date/show-estimated-delivery-date/show-estimated-delivery-date.module.ts:L28-L35, feature-libs/estimated-delivery-date/show-estimated-delivery-date/config/default-occ-cart-with-edd.config.ts:L10-L28).

- **Store finder**: un solo componente CMS (`StoreFinderComponent`) con *child routes* che montano i sotto-componenti; stato NgRx `stores` con due slice loader; rendering mappa via `GoogleMapRendererService` (feature-libs/storefinder/components/store-finder-components.module.ts:L66-L99, feature-libs/storefinder/core/store/store-finder-state.ts:L10-L29).
- **Pickup in store**: si dichiara dipendenza di `addToCart` e `cartBase` così da essere caricato prima di loro, sostituisce (REPLACE) gli outlet di "opzione di consegna" del PDP e del carrello, e apre un dialog di selezione negozio basato su stock (feature-libs/pickup-in-store/root/pickup-in-store-root.module.ts:L39-L60).

feature-libs/requested-delivery-date/styles/_requested-delivery-date.scss	Regole globali per cx-request-delivery-date e per .cx-review-card-shipping del checkout (:L1-L25).
feature-libs/requested-delivery-date/schematics/add-requested-delivery-date/index.ts	Factory ng-add addRequestedDeliveryDateFeature (:L25-L45).
feature-libs/requested-delivery-date/schematics/add-requested-delivery-date/index_spec.ts	Test Jest dello schematic (:L21-L131).
feature-libs/requested-delivery-date/vitest.config.ts	Config Vitest (:L14-L58).
feature-libs/storefinder/public_api.ts	Entry point principale: riesporta store-finder.module (:L10-L10).
feature-libs/storefinder/_index.scss	Entry Sass: core + styles/index (:L1-L2).
feature-libs/storefinder/schematics/add-storefinder/index.ts	Factory ng-add addStorefinderFeatures (:L25-L45).
feature-libs/storefinder/schematics/add-storefinder/index_spec.ts	Test Jest dello schematic (:L21-L125).
feature-libs/storefinder/vitest.config.ts	Config Vitest con resolve.alias verso helper di test di core/storefront (:L16-L22).

3. Come funziona passo per passo

3.1 Requested Delivery Date

Wiring. Il root module fa due cose: dichiara la config CMS lazy della feature requestedDeliveryDate (componenti DeliveryModeDatePickerComponent e OrderOverviewDeliveryDateComponent) mappando la feature core sulla principale — "by default core is bundled together with components" — e registra **eagerly** due outlet AFTER (feature-libs/requested-delivery-date/root/requested-delivery-date-root.module.ts:L18-L50). Gli outlet hanno id cx-delivery-mode e cx-order-overview (feature-libs/cart/base/root/models/cart-outlets.model.ts:L23-L24): il primo è renderizzato dal componente delivery mode del checkout (feature-libs/checkout/base/components/checkout-delivery-mode/checkout-delivery-mode.component.html:L55-L55), il secondo dall'order overview (feature-libs/order/components/order-details/order-overview/order-overview.component.html:L43-L43).

Particolarità: i componenti vivono nell'entry point root ("Make components available without being CMS driven") (feature-libs/requested-delivery-date/root/public_api.ts:L7-L11). Questo è necessario perché provideOutlet riceve direttamente la classe del componente, quindi il componente deve essere disponibile già nel bundle eager. Il modulo "pesante" RequestedDeliveryDateModule contiene solo core + OCC (feature-libs/requested-delivery-date/requested-delivery-date.module.ts:L11-L14).

Facade. RequestedDeliveryDateFacade è un facade lazy (facadeFactory) con un solo metodo, setRequestedDeliveryDate(userId, cartId, requestedDate): Observable<{}>, senza async (feature-libs/requested-delivery-date/root/facade/requested-delivery-date.facade.ts:L12-L32). Al primo uso il facade

risolve la feature `requestedDeliveryDate`, il cui modulo core lega `RequestedDeliveryDateFacade → useExisting: RequestedDeliveryDateService` e registra un `HttpErrorHandler` multi (feature-libs/requested-delivery-date/core/requested-delivery-date-core.module.ts:L14-L29). Il service delega direttamente al connector, il connector all'adapter astratto (feature-libs/requested-delivery-date/core/services/requested-delivery-date.service.ts:L19-L29, feature-libs/requested-delivery-date/core/connectors/requested-delivery-date.connector.ts:L17-L23). Nessun NgRx, nessuna `Command`: la chiamata HTTP parte alla subscribe.

Modello. La lib augmenta `Cart` con `earliestRetrievalAt` e `requestedRetrievalAt` e `Order` con `requestedRetrievalAt` (stringhe) (feature-libs/requested-delivery-date/root/model/augmented-core.model.ts:L10-L21). La data minima arriva dal backend dentro il carrello.

Componente picker. `DeliveryModeDatePickerComponent` (selector `cx-request-delivery-date`) inietta facade, `DateValidationService`, `EventService`, `GlobalMessageService` e, opzionalmente, `OutletContextData` (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L38-L62). Passi di `ngOnInit`:

1. si sottoscrive a `context$` dell'outlet e legge `context.item` (il cart) e `context.readonly` (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L74-L82);
2. se c'è `earliestRetrievalAt` valido lo memorizza; se il cart ha già `requestedRetrievalAt` lo usa, altrimenti imposta `requestedRetrievalAt = earliestRetrievalAt` e chiama **subito** `setRequestedDeliveryDate()` — cioè apre la pagina e scrive sul backend (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L84-L99).

`setRequestedDeliveryDate()` esce senza fare nulla se mancano userId, cartId o data, se la data non è valida o è precedente a `earliestRetrievalAt` (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L129-L145). Altrimenti chiama il facade; al successo dispatcha `CheckoutSupportedDeliveryModesQueryReloadEvent` (la lista dei delivery mode può dipendere dalla data) e un global message INFO; in errore mostra un messaggio solo se nella risposta ci sono errori `UnknownResourceError` (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L146-L176).

Il template mostra il picker solo se esiste `earliestRetrievalAt`; in modalità readonly mostra una `cx-card`, altrimenti `cx-date-picker` con `[min]="earliestRetrievalAt"` e `(update)="setRequestedDeliveryDate()"` (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.html:L1-L23).

Adapter OCC. L'endpoint di default è `requestedDeliveryDate: 'users/${userId}/carts/${cartId}/requestedretrievaldate'` (feature-libs/requested-delivery-date/occ/config/default-occ-requested-delivery-date-config.ts:L9-L18), aggiunto a `OccEndpoints` via augmentation (feature-libs/requested-delivery-date/occ/model/occ-requested-delivery-date-endpoints.model.ts:L9-L17). `OccRequestedDeliveryDateAdapter` costruisce header form-urlencoded con `USE_CLIENT_TOKEN`, mette la data in query string (`requestedRetrievalAt`) e chiama `this.http.put(url, { headers })` (feature-libs/requested-delivery-date/occ/adapters/occ-requested-delivery-date.adapter.ts:L25-L44). Attenzione: in `HttpClient.put` il secondo argomento è il **body** (angular:packages/common/http/src/client.ts:L4451-L4454) — vedi trappola T1 in sezione 9.

Errori. Due percorsi distinti: `RequestedDeliveryDateBadRequestHandler` (globale, registrato come `HttpErrorHandler` multi) intercetta solo i 400 con errore `ValidationError` + messaggio `checkout.multi.requestedretrievaldatevalid.error`, priorità `NORMAL` (feature-libs/requested-delivery-date/core/http-interceptors/bad-request/requested-delivery-date-badrequest.handler.ts:L20-L48); il componente gestisce gli `UnknownResourceError`. Il meccanismo degli `HttpErrorHandler` è descritto nel capitolo 41.

Order overview. `OrderOverviewDeliveryDateComponent` legge l'ordine da `context.item` dell'outlet e mostra una card intitolata `requestedDeliveryDate.readOnlyTextLabel` (feature-libs/requested-delivery-date/root/components/order-overview-delivery-date/order-overview-delivery-date.component.ts:L31-L61).

Date. `DateValidationService` presume il formato `dd-mm-yyyy` e lo converte in `mm/dd/yyyy` con una regex prima di `new Date` (feature-libs/requested-delivery-date/root/components/shared/date-validation.service.ts:L33-L35); `isDateGreaterOrEqual` restituisce `false` se una delle due stringhe è vuota (feature-libs/requested-delivery-date/root/components/shared/date-validation.service.ts:L43-L51).

3.2 Estimated Delivery Date

Wiring. `EstimatedDeliveryDateRootModule` è un `@NgModule({})` vuoto (feature-libs/estimated-delivery-date/root/estimated-delivery-date-root.module.ts:L9-L10). La costante `estimatedDeliveryDate` esiste (feature-libs/estimated-delivery-date/root/feature-name.ts:L7-L7) ma la demo non la usa come feature lazy. Se la variabile `CX_ESTIMATED_DELIVERY_DATE` è attiva (`environment.estimatedDeliveryDate`, default `false`: projects/storefrontapp/src/environments/environment.ts:L39-L39), la demo aggiunge `EstimatedDeliveryDateModule` alle `extensions` di `CartBaseWrapperModule`, quindi l'EDD **viaggia nello stesso chunk del carrello** (projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L16-L18); altrimenti non viene caricato. La stessa condizione governa `EstimatedDeliveryDateFeatureModule` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L167-L169). Il feature module EDD della demo importa solo il root module vuoto e la config i18n (projects/storefrontapp/src/app/spartacus/features/estimated-delivery-date/estimated-delivery-date-feature.module.ts:L18-L35).

`EstimatedDeliveryDateModule` importa solo `ShowEstimatedDeliveryDateModule` (feature-libs/estimated-delivery-date/estimated-delivery-date.module.ts:L10-L13), che fa due cose (feature-libs/estimated-delivery-date/show-estimated-delivery-date/show-estimated-delivery-date.module.ts:L28-L35):

1. `provideDefaultConfig(defaultOccCartWithEddConfig)`: ridefinisce gli endpoint `carts`, `cart`, `createCart` aggiungendo `arrivalSlots` dentro `entries(...)` (feature-libs/estimated-delivery-date/show-estimated-delivery-date/config/default-occ-cart-with-edd.config.ts:L10-L28). L'endpoint `cart` di default della cart lib è identico tranne per l'assenza di `arrivalSlots` (feature-libs/cart/base/occ/config/default-occ-cart-config-factory.ts:L17-L17).
2. `provideOutlet` AFTER su `CartOutlets.ITEM_DETAILS` (`cx-cart-item.details`), renderizzato da `cart-item` e `cart-item-list-row` (feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.html:L54-L54, feature-libs/cart/base/root/models/cart-outlets.model.ts:L13-L13).

Chi vince sugli endpoint? Nel chunk lazy le `DefaultConfigChunk` vengono fuse in ordine con `deepMerge` dentro `ambientDefaultConfig`; la config unificata è poi `defaultConfig` < `ambientDefaultConfig` < `ambientConfig` < `rootConfig` (core-libs/core/src/config/services/configuration.service.ts:L76-L100). `deepMerge` sostituisce le stringhe (core-libs/core/src/config/utils/deep-merge.ts:L31-L48). Nella demo `CartBaseModule` (che tramite `CartBaseOccModule` fornisce `defaultOccCartConfigFactory`) è importato prima dell'EDD (projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L22-L25, feature-libs/cart/base/cart-base.module.ts:L12-L15, feature-libs/cart/base/occ/cart-base-occ.module.ts:L35-L35), quindi la chunk EDD è più avanti nella lista e vince. `DA VERIFICARE`: che l'ordine dei provider `multi` nel module injector segua sempre l'ordine degli `imports` è un comportamento di Angular non riverificato qui per questo caso; e una `provideConfig` applicativa sugli stessi endpoint (rootConfig/ambientConfig) prevale comunque sull'EDD.

Modello. `ArrivalSlots {at?: Date; quantity?: number}`, `ArrivalSlot {at?: Date}` (feature-libs/estimated-delivery-date/root/model/estimated-delivery-date.model.ts:L7-L13); augmentation `OrderEntry`.

`arrivalSlots?: ArrivalSlots[]` e `Consignment.arrivalSlot?: ArrivalSlot` (feature-libs/estimated-delivery-date/root/model/augmented-core.model.ts:L11-L21).

Componente. `EstimatedDeliveryDateComponent` usa `inject()`: `orderEntry$` è `cartItemContext?.item$ ?? EMPTY` (feature-libs/estimated-delivery-date/show-estimated-delivery-date/components/estimated-delivery-date.component.ts:L25-L32); `consignments$` appiattisce le consignment dell'ordine corrente (da `OrderHistoryFacade.getOrderDetails()`) con `switchMap` su array, emettendo una consignment alla volta (feature-libs/estimated-delivery-date/show-estimated-delivery-date/components/estimated-delivery-date.component.ts:L34-L37).

Il template (feature-libs/estimated-delivery-date/show-estimated-delivery-date/components/estimated-delivery-date.component.html:L1-L56):

- per ogni arrival slot dell'entry crea un testo `cx-visually-hidden` collegato con `aria-describedby` e i valori visibili `aria-hidden` (`:L4-L29`);
- se lo slot 0 non ha `quantity` mostra un riepilogo ETA con la data del primo slot (`:L30-L37`);
- in fallback mostra l'ETA della consignment solo se la consignment ha uno slot **e** l'entry non ne ha (`:L42-L56`);
- le date sono formattate con `cxDate: 'M/d/yyyy'`, formato fisso (`:L19-L22`).

3.3 Store finder — wiring e routing

`StoreFinderRootModule` fornisce layout config, routing config e la CMS config lazy con il solo `StoreFinderComponent` per la feature `storeFinder` (feature-libs/storefinder/root/store-finder-root.module.ts:L17-L38, feature-libs/storefinder/root/feature-name.ts:L7-L7). Il layout `StoreFinderPageTemplate` usa gli slot `MiddleContent`, `SideContent` (feature-libs/storefinder/root/config/default-store-finder-layout-config.ts:L9-L15). Le rotte semantiche sono `storeFinder`, `storeFinderFind`, `storeFinderViewAll`, `storeFinderCountry`, `storeFinderRegion`, `storeFinderStore` (quest'ultima con due path) (feature-libs/storefinder/root/config/default-store-finder-routing-config.ts:L9-L35).

La navigazione interna non passa da pagine CMS diverse: il componente CMS `StoreFinderComponent` dichiara `childRoutes` che montano i sotto-componenti (`find` → `StoreFinderSearchResultComponent`, `view-all` → `StoreFinderStoresCountComponent`, `country/:country` e `country/:country/region/:region` → `StoreFinderGridComponent`, i due path con `:store` → `StoreFinderStoreComponent`) (feature-libs/storefinder/components/store-finder-components.module.ts:L66-L99). Il componente stesso è solo un guscio con header e `<router-outlet />` (feature-libs/storefinder/components/store-finder/store-finder.component.html:L1-L4). Il meccanismo `childRoutes` è spiegato nel capitolo 16 e nel capitolo 14.

`StoreFinderComponentsModule` importa **di nuovo** `StoreFinderCoreModule` (feature-libs/storefinder/components/store-finder-components.module.ts:L38-L65), oltre a `StoreFinderModule` che importa Core, Occ e Components (feature-libs/storefinder/store-finder.module.ts:L12-L19): nessun danno (NgModule deduplica), ma è utile saperlo se si compone il modulo a mano.

3.4 Store finder — facade, service, NgRx

Facade. `StoreFinderFacade` è `async: true` e proxa 10 metodi; i tre deprecati (`getStoreLatitude`, `getStoreLongitude`, `getDirections`) sono dichiarati astratti ma **non** compaiono nella lista `methods` (feature-libs/storefinder/root/facade/store-finder.facade.ts:L21-L72). `FacadeFactoryService` crea proprietà solo per i metodi elencati, e con `async` aggiunge un `delay(0)` alla risoluzione (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L53-L55, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L109-L125). Il core lega `StoreFinderFacade → useExisting: StoreFinderService` (feature-libs/storefinder/core/facade/facade-providers.ts:L11-L14).

Stato. Chiave NgRx `stores`, entity type loader `'[StoreFinder] Store Finder Data'`, stato `{findStores, viewAllStores}` entrambi `LoaderState` (feature-libs/storefinder/core/store/store-finder-state.ts:L10-L29). `StoreFinderStoreModule` registra `StoreModule.forFeature('stores', reducerToken, {metaReducers})` ed `EffectsModule.forFeature(effects)` (feature-libs/storefinder/core/store/store-finder-store.module.ts:L17-L27). Entrambi i sotto-reducer sono avvolti in `loaderReducer` con **lo stesso** entity type (feature-libs/storefinder/core/store/reducers/index.ts:L21-L29); `loaderReducer` reagisce a ogni azione con `meta.entityType` uguale (core-libs/core/src/state/utils/loader/loader.reducer.ts:L32-L60) — vedi T9.

Ricerca. `StoreFinderService.findStoresAction(...)` (feature-libs/storefinder/core/facade/store-finder.service.ts:L106-L153):

- senza `useMyLocation` dispatcha direttamente `FindStores` (azione loader "load");
- con `useMyLocation` dispatcha `FindStoresOnHold` (stato loading), avvia `navigator.geolocation.watchPosition` e alla prima posizione dispatcha `FindStores` con `longitudeLatitude`; in errore mostra il global message `storeFinder.geolocationNotEnabled` e naviga a `/store-finder`.

Tutte le dispatch passano da `clearWatchGeolocation`, che chiude l'eventuale watch attivo (feature-libs/storefinder/core/facade/store-finder.service.ts:L172-L180).

`FindStoresEffect.findStores$` usa `mergeMap`, chiama il connector e, se c'è `countryIsoCode`, filtra gli store per paese **lato client** e li ordina per `name` (feature-libs/storefinder/core/store/effects/find-stores.effect.ts:L24-L62); `findStoreById$` usa `switchMap` (feature-libs/storefinder/core/store/effects/find-stores.effect.ts:L64-L84). Il reducer salva il payload di `FIND_STORES_SUCCESS` in `findStoresEntities` e quello di `FIND_STORE_BY_ID_SUCCESS` in `findStoreEntityById` (feature-libs/storefinder/core/store/reducers/find-stores.reducer.ts:L10-L33).

Conteggi. `viewAllStores$` reagisce a `VIEW_ALL_STORES` **e** a `CLEAR_STORE_FINDER_DATA`, carica i conteggi e li ordina per nome (feature-libs/storefinder/core/store/effects/view-all-stores.effect.ts:L28-L55).

Cambio contesto. `clearStoreFinderData$` mappa `LANGUAGE_CHANGE` e `CURRENCY_CHANGE` in `ClearStoreFinderData` (feature-libs/storefinder/core/store/effects/view-all-stores.effect.ts:L57-L68); il meta reducer `clearStoreFinderState` azzera lo stato su `LANGUAGE_CHANGE` e `CLEAR_STORE_FINDER_DATA` (feature-libs/storefinder/core/store/reducers/index.ts:L39-L53). A quel punto `StoreFinderService.reloadStoreEntitiesOnContextChange()` — avviato nel costruttore, solo in browser o senza `platformId` — vede entità vuote e non in caricamento, e ricarica per `country` o per `store` leggendo i route params (feature-libs/storefinder/core/facade/store-finder.service.ts:L191-L213). `callFindStoresAction` cerca con query vuota, `pageSize: -1` e il paese dai route params (feature-libs/storefinder/core/facade/store-finder.service.ts:L215-L224).

OCC. Endpoint: `store: 'stores/${storeId}?fields=FULL'`, `stores: 'stores?fields=stores(...),pagination(DEFAULT),sorts(DEFAULT)'`, `storescounts: 'stores/storescounts'` (feature-libs/storefinder/occ/adapters/default-occ-store-finder-config.ts:L9-L20). `callOccFindStores` invia `longitude`/`latitude` **al posto** di `query` se c'è una posizione, e aggiunge `radius`, `pageSize`, `currentPage`, `sort` solo se truthy (feature-libs/storefinder/occ/adapters/occ-store-finder.adapter.ts:L71-L103). `search` converte con `STORE_FINDER_SEARCH_PAGE_NORMALIZER`, `loadCounts` estrae `countriesAndRegionsStoreCount` e applica `STORE_COUNT_NORMALIZER`, `load` usa `POINT_OF_SERVICE_NORMALIZER` del core (feature-libs/storefinder/occ/adapters/occ-store-finder.adapter.ts:L36-L69). Il connector rinomina `getCounts()` → `loadCounts()` e `get(id)` → `load(id)` (feature-libs/storefinder/core/connectors/store-finder.connector.ts:L26-L32).

3.5 Store finder — componenti e Google Maps

- `StoreFinderSearchComponent` naviga a `store-finder/find` con query param `query` o `useMyLocation: true` (feature-libs/storefinder/components/store-finder-search/store-finder-search.component.ts:L47-

L61); il template ha due varianti governate da `*cxFeature="'a11yStoreFinderLabel'"` (feature-libs/storefinder/components/store-finder-search/store-finder-search.component.html:L2-L2).

- `StoreFinderSearchResultComponent` a ogni cambio di `queryParams` ricalcola la ricerca con `currentPage: 0` e `radius = googleMaps.radius`, chiamando `findStoresAction` (feature-libs/storefinder/components/store-finder-search-result/store-finder-search-result.component.ts:L52-L92); `viewPage` riesegue con la nuova pagina (feature-libs/storefinder/components/store-finder-search-result/store-finder-search-result.component.ts:L64-L74).
- `StoreFinderListComponent` alterna lista/mappa, centra la mappa sullo store cliccato, scrolla all'item selezionato dalla mappa (feature-libs/storefinder/components/store-finder-search-result/store-finder-list/store-finder-list.component.ts:L85-L122); con toggle `a11yStoreFinderFocusOnBackButton` un `effect()` sul signal `viewChild` sposta il focus sul back button (feature-libs/storefinder/components/store-finder-search-result/store-finder-list/store-finder-list.component.ts:L68-L83).
- `StoreFinderMapComponent` chiama il renderer a ogni `ngOnChanges` di `locations` e riemette l'indice del marker cliccato (feature-libs/storefinder/components/store-finder-map/store-finder-map.component.ts:L33-L60).
- `StoreFinderGridComponent` (OnPush) su init chiama `callFindStoresAction(route.snapshot.params)` se c'è `country` (feature-libs/storefinder/components/store-finder-grid/store-finder-grid.component.ts:L41-L52); `StoreFinderStoreComponent` carica lo store da `route.snapshot.params.store` se non riceve `@Input() location` (feature-libs/storefinder/components/store-finder-store/store-finder-store.component.ts:L46-L56); `StoreFinderStoresCountComponent` dispatcha `viewAllStores()` (feature-libs/storefinder/components/store-finder-stores-count/store-finder-stores-count.component.ts:L41-L50).
- `StoreFinderListItemComponent` espone l'outlet `StoreFinderOutlets.PREFERRED_STORE` (`cx-pick-up-in-store-make-my-store`) con contesto `{displayName, name}` (feature-libs/storefinder/components/store-finder-list-item/store-finder-list-item.component.html:L41-L47, feature-libs/storefinder/root/model/store-entities.model.ts:L9-L15): è il punto in cui pickup-in-store inietta il bottone "imposta come negozio preferito".

`GoogleMapRendererService.renderMap` (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L44-L68):

1. senza `googleMaps.apiKey` esce (con `warn` solo in dev mode);
2. esce se `locations[0]` è un oggetto vuoto;
3. se la mappa non esiste ancora carica lo script (`embedMapScript`), altrimenti ridisegna.

`embedMapScript` invia la chiave vuota se è il valore speciale `'cx-development'` (`GOOGLE_MAPS_DEVELOPMENT_KEY_CONFIG`, feature-libs/storefinder/root/config/constants.ts:L7-L7), e carica lo script con `ScriptLoader.embedScript` (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L82-L116). Con il toggle `useGoogleMapsAsyncLoading` aggiunge `loading: 'async'` + un `callback` globale; con `useAdvancedGoogleMarkers` aggiunge `libraries: 'marker'` (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L87-L108). Il callback globale ha nome univoco `__spartacusGoogleMapsInit_<n>`, si auto-cancella e non viene registrato se `document.defaultView` è null (SSR) (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L125-L142). `initMap` usa `gestureHandling: 'greedy'`, `zoom = googleMaps.scale` e `mapId` solo con advanced markers (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L175-L193). Advanced markers: `PinElement` con `glyphText` numerico, evento `gmp-click`, store senza geolocazione saltati (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L204-L250); il ramo legacy usa `google.maps.Marker` e i metodi deprecati di `StoreFinderService` (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L251-L275).

La demo usa la chiave speciale per mostrare la mappa senza chiave ("for development or demo purposes") (projects/storefrontapp/src/app/private/private.providers.ts:L46-L49).

3.6 Pickup in store — wiring

PickupInStoreRootModule (feature-libs/pickup-in-store/root/pickup-in-store-root.module.ts:L23-L60):

1. CMS lazy per la feature pickupInStore: CheckoutReviewPickup, MyPreferredStoreComponent, OrderConfirmationPickUpComponent, PickupInStoreDeliveryModeComponent; pickupInStoreCore → pickupInStore;
2. aggiunge pickupInStore alle dependencies delle feature ADD_TO_CART_FEATURE e CART_BASE_FEATURE ("make pickup lib loaded before add-to-cart" / "before cart base"). Così, quando la feature add-to-cart o cart-base viene caricata, il chunk pickup è già caricato e i suoi provideOutlet (REPLACE) sono registrati.

Inoltre il root augmenta **a runtime** l'enum LAUNCH_CALLER con PICKUP_IN_STORE (dichiarazione TypeScript + assegnazione) (feature-libs/pickup-in-store/root/model/augmented-core.model.ts:L9-L15). I modelli principali: PickupOption = 'delivery' | 'pickup', AugmentedPointOfService = PointOfService & {pickupOption} (feature-libs/pickup-in-store/root/model/pickup-option.model.ts:L9-L15); StockLocationSearchParams = {productCode} & ({latitude, longitude} | {location}) (feature-libs/pickup-in-store/root/model/stock-location-search-params.model.ts:L7-L26). La chiave localStorage del negozio preferito è preferred_store (feature-libs/pickup-in-store/root/pickup-in-store-constants.ts:L7-L8).

Quattro facade lazy async: true sulla feature pickupInStoreCore (feature-libs/pickup-in-store/root/facade/intended-pickup-location.facade.ts:L19-L34, feature-libs/pickup-in-store/root/facade/pickup-locations-search.facade.ts:L22-L45, feature-libs/pickup-in-store/root/facade/pickup-option.facade.ts:L13-L27, feature-libs/pickup-in-store/root/facade/preferred-store.facade.ts:L16-L30), legate ai service via useExisting (feature-libs/pickup-in-store/core/facade/facade-providers.ts:L19-L37). PickupInStoreCoreModule fornisce config, StockConnector, PickupLocationConnector, facade providers e lo store module (feature-libs/pickup-in-store/core/pickup-in-store-core.module.ts:L14-L23).

3.7 Pickup in store — stato NgRx

Tre feature NgRx: pickup-locations, pickup-option, stock (feature-libs/pickup-in-store/core/store/pickup-in-store-store.module.ts:L29-L53).

FEATURE	FORMA	RIFERIMENTO
pickup-locations	{defaultPointOfService, intendedPickupLocations (per productCode), storeDetails (per nome)}	feature-libs/pickup-in-store/core/store/pickup-location-state.ts:L19-L27
pickup-option	{pageContext: string, pickupOption: {entryNumber, pickupOption}[]}	feature-libs/pickup-in-store/core/store/pickup-option-state.ts:L15-L23
stock	{browserLocation, hideOutOfStock, stockLevel: LoaderState<Record<productCode, …>>, stockLevelAtStore}	feature-libs/pickup-in-store/core/store/stock-state.ts:L21-L28

Punti salienti:

- intendedPickupLocationsReducer: AddLocation sostituisce, RemoveLocation scrive {pickupOption: 'delivery'} invece di cancellare, SetPickupOption fonde il pickupOption (feature-libs/pickup-in-store/core/store/reducers/pickup-locations/pickup-locations.reducer.ts:L14-L31).
- pickupOptionReducer: RemovePickupOption rimuove e decrementa gli entryNumber successivi, rispecchiando la rinumerazione delle entry del carrello (feature-libs/pickup-in-store/core/store/reducers/

pickup-option/pickup-option.reducer.ts:L13-L42).

- Il meta reducer `clearStockState`, su `CLEAR_STOCK_DATA`, passa `undefined` al reducer, che quindi riporta tutta la feature `stock` allo stato iniziale (feature-libs/pickup-in-store/core/store/reducers/stock/index.ts:L42-L54).
- `stockAtStoreReducer` scrive `[productCode]: { [storeName]: stockLevel }`, sostituendo l'intero oggetto del prodotto (feature-libs/pickup-in-store/core/store/reducers/stock/stock-level.reducer.ts:L45-L51).
- `getPickupOptionByProductCode` restituisce `'delivery'` come default (feature-libs/pickup-in-store/core/store/selectors/pickup-locations.selectors.ts:L48-L55); `getStoresWithStockForProductCode` filtra con `storeHasStock` solo se `hideOutOfStock` è true (feature-libs/pickup-in-store/core/store/selectors/stock.selectors.ts:L61-L71); `isInStock` considera non disponibili sia `outOfStock` sia `lowStock` (feature-libs/pickup-in-store/core/utils/utils.ts:L9-L19).

Effetti:

- `StockEffect.loadStockLevels$` (`switchMap`): separa `productCode` dal resto dei parametri, chiama `GET products/${productCode}/stock` con `location` o `latitude/longitude` + `fields: 'FULL'`, errore → `StockLevelFail` (feature-libs/pickup-in-store/core/store/effects/stock.effect.ts:L26-L49, feature-libs/pickup-in-store/occ/adapters/occ-stock.adapter.ts:L35-L51).
- `loadStockLevelAtStore$` (`concatMap`) **senza** `catchError` (feature-libs/pickup-in-store/core/store/effects/stock.effect.ts:L51-L65).
- `PickupLocationEffect.storeDetails$` (`mergeMap`) → `SetStoreDetailsSuccess`/`SetStoreDetailsFailure` (feature-libs/pickup-in-store/core/store/effects/pickup-location.effect.ts:L26-L51); `SetStoreDetailsFailure` è un wrapper che aggiunge all'azione la proprietà `error` (uguale a `payload`) per farsi riconoscere da `CxErrorHandlerEffect` (feature-libs/pickup-in-store/core/store/actions/pickup-location.action.ts:L83-L102).
- `loadDefaultPointOfService$`: se il profilo utente ha `defaultPointOfServiceName` usa quello (con `displayName: ''`), altrimenti legge `preferred_store` dal localStorage; in errore emette uno store vuoto (feature-libs/pickup-in-store/core/store/effects/default-point-of-service-name.effect.ts:L39-L81).
- `setDefaultPointOfService$`: salva in localStorage, aggiorna il profilo (`defaultPointOfServiceName`), e termina sempre con `LoadDefaultPointOfService()` (feature-libs/pickup-in-store/core/store/effects/default-point-of-service-name.effect.ts:L83-L107).

3.8 Pickup in store — flussi UI

Outlet registrati (feature-libs/pickup-in-store/components/container/cart-pickup-options-container/cart-pickup-options-container.module.ts:L23-L27, feature-libs/pickup-in-store/components/container/pdp-pickup-options-container/pdp-pickup-options-container.module.ts:L23-L27, feature-libs/pickup-in-store/components/container/pickup-info-container/pickup-info-container.module.ts:L19-L23, feature-libs/pickup-in-store/components/container/pickup-in-store-order-consignment/pickup-in-store-order-consignment-container.module.ts:L22-L26, feature-libs/pickup-in-store/components/container/set-preferred-store/set-preferred-store.module.ts:L28-L32):

OUTLET	POSIZIONE	COMPONENTE
`CartOutlets.ITEM_DELIVERY_DETAILS`	REPLACE	`CartPickupOptionsContainerComponent`
`CartOutlets.ADD_TO_CART_PICKUP_OPTION`	REPLACE	`PdpPickupOptionsContainerComponent`
`CartOutlets.PICKUP_INFO`	REPLACE	`PickupInfoContainerComponent`

OUTLET	POSIZIONE	COMPONENTE
OrderOutlets.ORDER_CONSIGNMENT	AFTER	container consignment
StoreFinderOutlets.PREFERRED_STORE	REPLACE	SetPreferredStoreComponent

Il dialog è registrato nella layout config: PICKUP_IN_STORE → PickupOptionDialogComponent, inlineRoot: true, DIALOG_TYPE.DIALOG (feature-libs/pickup-in-store/components/container/pickup-option-dialog/pickup-option-dialog-layout.config.ts:L10-L18).

PDP + add to cart. AddToCartComponent rende l'outlet ADD_TO_CART_PICKUP_OPTION con cxComponentRef e, al click, legge intendedPickupLocation$ dell'istanza del componente PDP: se pickupOption === 'pickup' passa il nome del negozio come pickupStore ad addEntry (feature-libs/cart/base/components/add-to-cart/add-to-cart.component.html:L23-L28, feature-libs/cart/base/components/add-to-cart/add-to-cart.component.ts:L267-L287). L'add to cart viene disabilitato se l'opzione è pickup ma manca displayName (feature-libs/cart/base/components/add-to-cart/add-to-cart.component.ts:L321-L335). Il container PDP imposta il pageContext 'PDP' e, se non c'è un'intended location con displayName, propone il negozio preferito con stock come pickupOption: 'delivery' (feature-libs/pickup-in-store/components/container/pdp-pickup-options-container/pdp-pickup-options-container.component.ts:L85-L173). Sul PDP il cambio opzione aggiorna solo lo stato intended (feature-libs/pickup-in-store/components/container/pdp-pickup-options-container/pdp-pickup-options-container.component.ts:L188-L196).

Dialog. Entrambi i container aprono il dialog con LAUNCH_CALLER.PICKUP_IN_STORE passando productCode (e entryNumber/quantity nel carrello) (feature-libs/pickup-in-store/components/container/cart-pickup-options-container/cart-pickup-options-container.component.ts:L295-L310). Nel dialog la ricerca chiama startSearch (→ StockLevel) (feature-libs/pickup-in-store/components/container/pickup-option-dialog/pickup-option-dialog.component.ts:L140-L145); StoreListComponent.onSelectStore toglie stockInfo e imposta l'intended location con pickupOption: 'pickup' (feature-libs/pickup-in-store/components/container/store-list/store-list.component.ts:L67-L76). La chiusura con selezione, **solo fuori dal PDP**, aggiorna l'entry con updateEntry(entryNumber, quantity, name, false) (feature-libs/pickup-in-store/components/container/pickup-option-dialog/pickup-option-dialog.component.ts:L171-L192). Click sull'host chiude senza selezione (feature-libs/pickup-in-store/components/container/pickup-option-dialog/pickup-option-dialog.component.ts:L93-L100).

Carrello. Il container carrello imposta il pageContext dall'id della pagina CMS e l'opzione corrente dall'esistenza di deliveryPointOfService sull'entry (feature-libs/pickup-in-store/components/container/cart-pickup-options-container/cart-pickup-options-container.component.ts:L128-L163). Cambio opzione: delivery → updateEntry(entry, qty, undefined, true); pickup → updateEntry(entry, qty, name, true) con il nome da storeDetails$ (feature-libs/pickup-in-store/components/container/cart-pickup-options-container/cart-pickup-options-container.component.ts:L255-L289). Nell'adapter OCC del carrello pickupStore === undefined && pickupToDelivery produce un PUT con sola quantity; altrimenti un PATCH con deliveryPointOfService (feature-libs/cart/base/occ/adapters/occ-cart-entry.adapter.ts:L86-L104). Il container è nascosto per entry di un ordine e per CartType.SELECTIVE (feature-libs/pickup-in-store/components/container/cart-pickup-options-container/cart-pickup-options-container.component.html:L1-L7), e i controlli sono disabilitati se lo stesso prodotto compare in più entry (feature-libs/pickup-in-store/components/container/cart-pickup-options-container/cart-pickup-options-container.component.ts:L165-L177).

Riepiloghi. Le tre CMS component di riepilogo (CheckoutReviewPickup, OrderConfirmationPickUpComponent, PickupInStoreDeliveryModeComponent) sono tutte PickUpItemsDetailsComponent con data diversa (feature-libs/pickup-in-store/components/container/pickup-items-details/pickup-items-details.module.ts:L33-L57); il componente sceglie ordine o carrello in base a data.context === 'order' (feature-libs/pickup-in-store/components/container/pickup-items-details/pickup-items-details.component.ts:L58-L72).

`DeliveryPointsService` raggruppa le entry pickup per negozio, carica i dettagli di ogni negozio e combina i risultati (feature-libs/pickup-in-store/components/services/delivery-points.service.ts:L66-L160).

Negozio preferito. `SetPreferredStoreComponent` riceve i nomi dal contesto outlet e chiama `setPreferredStore` (feature-libs/pickup-in-store/components/container/set-preferred-store/set-preferred-store.component.ts:L42-L57). `PreferredStoreService` dispatcha `LoadDefaultPointOfService()` nel costruttore (feature-libs/pickup-in-store/core/services/preferred-store.service.ts:L32-L41); `getPreferredStoreWithProductInStock` richiede lo stock al negozio preferito ed emette solo se `isInStock` (feature-libs/pickup-in-store/core/services/preferred-store.service.ts:L73-L97). `MyPreferredStoreComponent` carica i dettagli del preferito e sulla pagina `storefinderPage` mostra solo l'azione "Get Directions" (feature-libs/pickup-in-store/components/container/my-preferred-store/my-preferred-store.component.ts:L100-L164).

Nella demo il pickup-in-store è aggiunto solo nel ramo non-B2B (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L117-L129).

3.9 Packaging: schematics, stili, test

Schematics `ng-add`**.** Le quattro factory sono identiche salvo il nome: validano l'installazione Spartacus da `package.json`, espandono le feature richieste con `analyzeCrossFeatureDependencies` e concatenano `analyzeApplication` → `addFeatures` → `addPackageJsonDependenciesForLibrary(peerDependencies)` → `finalizeInstallation` (feature-libs/estimated-delivery-date/schematics/add-estimated-delivery-date/index.ts:L25-L45, feature-libs/pickup-in-store/schematics/add-pickup-in-store/index.ts:L25-L45, feature-libs/requested-delivery-date/schematics/add-requested-delivery-date/index.ts:L25-L45, feature-libs/storefinder/schematics/add-storefinder/index.ts:L25-L45). Il test EDD verifica che il modulo lazy finisca nel wrapper `cart-base` e che **non** vengano creati i feature module user/order (feature-libs/estimated-delivery-date/schematics/add-estimated-delivery-date/index_spec.ts:L110-L126), coerente con la T10 (EDD viaggia col chunk del carrello).

Stili globali vs allowlist. Pickup-in-store e storefinder usano placeholder + allowlist (vedi sezione 8), mentre RDD ed EDD scrivono regole dirette sui selettori: `$skipComponentStyles` non ha effetto su di esse (feature-libs/requested-delivery-date/styles/_requested-delivery-date.scss:L1-L25, feature-libs/estimated-delivery-date/styles/_estimated-delivery-date.scss:L1-L23). In particolare RDD azzera il `padding-bottom` delle card dentro `.cx-review-card-shipping`, classe del riepilogo checkout definita fuori dalla lib (feature-libs/requested-delivery-date/styles/_requested-delivery-date.scss:L15-L25, feature-libs/checkout/base/components/checkout-review-submit/checkout-review-submit.component.html:L58-L58): importare gli stili RDD cambia la review anche quando il date picker non è presente. Il root `_index.scss` del pickup assegna `$cx-color-link-primary: #1672b7` senza `!default` prima degli import, quindi un valore impostato prima dall'app viene sovrascritto (feature-libs/pickup-in-store/_index.scss:L1-L7, feature-libs/pickup-in-store/styles/_store.scss:L29-L29).

Test. Le tre config Vitest condividono forks/jsdom/`setup-vitest.ts` e soglie 85/85/65/85; storefinder aggiunge alias di path per gli helper di test importati con path relativi alla root (feature-libs/storefinder/vitest.config.ts:L16-L22, feature-libs/storefinder/vitest.config.ts:L51-L56, feature-libs/requested-delivery-date/vitest.config.ts:L42-L47, feature-libs/estimated-delivery-date/vitest.config.ts:L41-L46).

              component: StoreFinderStoresCountComponent,
            },
            {
              path: 'country/:country',
              component: StoreFinderGridComponent,
            },
            // ...
            {
              path: 'country/:country/:store',
              component: StoreFinderStoreComponent,
            },
          ],
        },
      },
    }),
```

5.7 Store finder: facade senza i metodi deprecati

feature-libs/storefinder/root/facade/store-finder.facade.ts:L21-L42

```ts
@Injectable({
  providedIn: 'root',
  useFactory: () =>
    facadeFactory({
      // @ts-ignore: Deprecated methods will be removed with next major release
      facade: StoreFinderFacade,
      feature: STORE_FINDER_FEATURE,
      methods: [
```

```
        'getStoresLoading',
        'getStoresLoaded',
        'getFindStoresEntities',
        'getViewAllStoresLoading',
        'getViewAllStoresEntities',
        'findStoresAction',
        'viewAllStores',
        'viewStoreById',
        'callFindStoresAction',
        'getFindStoreEntityById',
      ],
      async: true,
    }),
})
```

5.8 Store finder: due loader sullo stesso entity type + meta reducer

feature-libs/storefinder/core/store/reducers/index.ts:L21-L51

```ts
export function getReducers(): ActionReducerMap<StoresState> {
  return {
    findStores: StateUtils.loaderReducer(STORE_FINDER_DATA, findStoresReducer),
    viewAllStores: StateUtils.loaderReducer(
      STORE_FINDER_DATA,
      viewAllStoresReducer
    ),
  };
}
// ...
export function clearStoreFinderState(
  reducer: ActionReducer<StoresState, Action>
): ActionReducer<StoresState, Action> {
  return function (state, action) {
    if (action.type === SiteContextActions.LANGUAGE_CHANGE) {
      state = undefined;
    }
    if (action.type === StoreFinderActions.CLEAR_STORE_FINDER_DATA) {
      state = undefined;
    }
    return reducer(state, action);
  };
}
```

5.9 Store finder: parametri OCC

feature-libs/storefinder/occ/adapters/occ-store-finder.adapter.ts:L77-L102

```ts
const params: any = {};

if (longitudeLatitude) {
  params['longitude'] = String(longitudeLatitude.longitude);
  params['latitude'] = String(longitudeLatitude.latitude);
} else {
  params['query'] = query;
}

if (radius) {
  params['radius'] = String(radius);
}

if (searchConfig?.pageSize) {
  params['pageSize'] = String(searchConfig.pageSize);
}
if (searchConfig?.currentPage) {
  params['currentPage'] = String(searchConfig.currentPage);
}
if (searchConfig?.sort) {
  params['sort'] = searchConfig.sort;
}

return this.http.get<Occ.StoreFinderSearchPage>(
  this.occEndpointsService.buildUrl('stores', { queryParams: params })
);
```

5.10 Google Maps: chiave di sviluppo e toggle

feature-libs/storefinder/core/service/google-map-renderer.service.ts:L82-L108

```ts
const apiKey =
  this.config.googleMaps?.apiKey === GOOGLE_MAPS_DEVELOPMENT_KEY_CONFIG
    ? ''
    : this.config.googleMaps?.apiKey;

const useAsyncLoading = this.featureToggles.useGoogleMapsAsyncLoading;

// With `loading=async`, Google invokes a global `callback` function once
// the API is ready instead of firing the script `load` event.
const callbackName = useAsyncLoading
  ? this.registerMapCallback(mapElement, locations, selectMarkerHandler)
  : undefined;

this.scriptLoader.embedScript({
  src: this.config.googleMaps?.apiUrl ?? '',
  params: {
    key: apiKey,
```

```
        // Opt into async loading to avoid Google's "loaded directly without
        // loading=async" performance warning.
        ...(useAsyncLoading
          ? { loading: 'async', callback: callbackName }
          : {}),
        // Advanced markers require the optional `marker` library.
        ...(this.featureToggles.useAdvancedGoogleMarkers
          ? { libraries: 'marker' }
          : {}),
```

5.11 Pickup: dipendenze di feature

feature-libs/pickup-in-store/root/pickup-in-store-root.module.ts:L39-L60

```ts
@NgModule({
  providers: [
    provideDefaultConfigFactory(defaultPickupInStoreComponentsConfig),
    // make pickup lib loaded before add-to-cart
    provideDefaultConfig({
      featureModules: {
        [ADD_TO_CART_FEATURE]: {
          dependencies: [PICKUP_IN_STORE_FEATURE],
        },
      },
    }),
    // make pickup lib loaded before cart base
    provideDefaultConfig({
      featureModules: {
        [CART_BASE_FEATURE]: {
          dependencies: [PICKUP_IN_STORE_FEATURE],
        },
      },
    }),
  ],
})
export class PickupInStoreRootModule {}
```

5.12 Pickup: effetto stock per negozio senza `catchError`

feature-libs/pickup-in-store/core/store/effects/stock.effect.ts:L51-L65

```ts
  loadStockLevelAtStore$ = createEffect(() =>
    this.actions$.pipe(
      ofType(StockLevelActions.STOCK_LEVEL_AT_STORE),
      map(({ payload }: StockLevelActions.StockLevelAtStoreAction) => payload),
      concatMap(({ productCode, storeName }) =>
        this.stockConnector.loadStockLevelAtStore(productCode, storeName).pipe(
```

```
          map((stockLevel) =>
            StockLevelActions.StockLevelAtStoreSuccess({
              payload: { productCode, storeName, stockLevel },
            })
          )
        )
      )
    )
  );
```

5.13 Pickup ↔ delivery nell'adapter del carrello

feature-libs/cart/base/occ/adapters/occ-cart-entry.adapter.ts:L86-L104

```ts
    // switch from pickup to delivery mode
    if (pickupStore === undefined && pickupToDelivery) {
      return this.http
        .put<CartModification>(url, { quantity: qty }, { headers })
        .pipe(this.converterService.pipeable(CART_MODIFICATION_NORMALIZER));
    }

    let params = {};
    if (pickupStore) {
      params = {
        deliveryPointOfService: {
          name: pickupStore,
        },
      };
    }

    return this.http
      .patch<CartModification>(url, { quantity: qty, ...params }, { headers })
      .pipe(this.converterService.pipeable(CART_MODIFICATION_NORMALIZER));
```

5.14 Pickup: negozio preferito (bug mascherato)

feature-libs/pickup-in-store/core/store/effects/default-point-of-service-name.effect.ts:L93-L106

```ts
      switchMap((preferredStore: PointOfServiceNames) =>
        this.userProfileService
          .update({
            defaultPointOfServiceName: preferredStore.name,
          })
          .pipe(
            map(() => DefaultPointOfServiceActions.LoadDefaultPointOfService()),
            catchError((_error) =>
              of(DefaultPointOfServiceActions.LoadDefaultPointOfService)
```

```
          )
        )
      ),
      map(() => DefaultPointOfServiceActions.LoadDefaultPointOfService())
```

Traduzioni `requestedDeliveryDate`, `storeFinder`, `pickupInStore`	i18n chunk	`feature-libs/pickup-in-store/assets/translations/translations.ts:L9-L25`	`/assets`	53 — traduzioni

Note pratiche:

- **Aggiungere campi al carrello senza perdere EDD.** Se l'app ridefinisce `backend.occ.endpoints.cart` con `provideConfig`, la sua stringa sostituisce sia quella della cart lib sia quella EDD (`core-libs/core/src/config/services/configuration.service.ts:L92-L100`): va incluso `arrivalSlots` a mano (stringa di riferimento in `feature-libs/estimated-delivery-date/show-estimated-delivery-date/config/default-occ-cart-with-edd.config.ts:L10-L28`). Ricetta: 52.
- **Componenti in outlet**: RDD/EDD/pickup usano `provideOutlet`. Per sostituire, ad esempio, il date picker si può registrare un altro `provideOutlet` sullo stesso id con `OutletPosition.REPLACE` o AFTER, come descritto nel capitolo 17 e in 51.
- **Store finder con un altro provider di mappe**: `GoogleMapRendererService` è `providedIn: 'root'` ed esportato; può essere sostituito via DI (`{ provide: GoogleMapRendererService, useClass: … }`), ricetta 50. `StoreFinderMapComponent` chiama solo `renderMap` e `centerMap` (`feature-libs/storefinder/components/store-finder-map/store-finder-map.component.ts:L45-L49`).

9. Trappole, casi limite, comportamenti controintuitivi

Requested delivery date

- **T1 — header passati come body.** `this.http.put(url, { headers })` passa l'oggetto `{headers}` come **body** (il secondo parametro di `put` è `body`), quindi `Content-Type: application/x-www-form-urlencoded` e l'header `USE_CLIENT_TOKEN` non vengono applicati come opzioni; il valore utile viaggia comunque in query string (feature-libs/requested-delivery-date/occ/adapters/occ-requested-delivery-date.adapter.ts:L43-L43, angular:packages/common/http/src/client.ts:L4451-L4454). DA VERIFICARE il comportamento del backend OCC con un body JSON `{"headers":{…}}`: nessun backend disponibile.
- **T2 — contesto sincrono.** `ngOnInit` legge `cartEntry` subito dopo la `subscribe` a `context$`: funziona solo se l'outlet emette sincronamente (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L75-L88).
- **T3 — scrittura all'apertura.** Se il cart non ha `requestedRetrievalAt`, la sola visualizzazione dello step delivery mode genera un `PUT` (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L89-L96).
- **T4 — due gestori d'errore** con lo stesso messaggio: componente (`UnknownResourceError`) e `HttpErrorHandler` globale (`ValidationError`) (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L172-L176, feature-libs/requested-delivery-date/core/http-interceptors/bad-request/requested-delivery-date-badrequest.handler.ts:L38-L44).
- **T5 — formato data.** `DateValidationService` presume `dd-mm-yyyy`; stringhe ISO non matchano la regex e passano invariate a `new Date` (feature-libs/requested-delivery-date/root/components/shared/date-validation.service.ts:L33-L35).

Estimated delivery date

- **T6 — `@Optional()` inutile.** Il decoratore è su un campo inizializzato con `inject(CartItemContext)` senza `{optional: true}`: non rende opzionale l'iniezione, e il fallback `?? EMPTY` non scatta se il token manca (feature-libs/estimated-delivery-date/show-estimated-delivery-date/components/estimated-delivery-date.component.ts:L26-L32).
- **T7 — `consignments$` al singolare.** È tipato `Observable<Consignment>` e il template lo usa come singola consignment; con più consignment emette in sequenza e il template mostra l'ultima (feature-libs/estimated-delivery-date/show-estimated-delivery-date/components/estimated-delivery-date.component.ts:L34-L37, feature-libs/estimated-delivery-date/show-estimated-delivery-date/components/estimated-delivery-date.component.html:L42-L52).
- **T8 — endpoint sostituiti interamente.** L'override EDD rimpiazza le stringhe `carts`/`cart`/`createCart` della cart lib; una personalizzazione applicativa le rimpiazza a sua volta (sezione 3.2; core-libs/core/src/config/services/configuration.service.ts:L76-L100).
- **T9 — data non localizzata.** Formato `M/d/yyyy` cablato nel template (feature-libs/estimated-delivery-date/show-estimated-delivery-date/components/estimated-delivery-date.component.html:L21-L21).
- **T10 — non è lazy nella demo.** Con `CX_ESTIMATED_DELIVERY_DATE` attiva, EDD arriva col chunk del carrello; con la build di default (`false`) non è presente affatto. Il root module è vuoto (projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L16-L18, projects/storefrontapp/src/environments/environment.ts:L39-L39).

Store finder

- **T11 — loader condiviso.** `findStores` e `viewAllStores` usano lo stesso entity type: un `FindStores` mette `loading: true` anche in `viewAllStores`, e un `ViewAllStoresSuccess` imposta `success: true` anche in `findStores` (il cui `value` resta quello calcolato da `findStoresReducer`, che ignora l'azione) (feature-libs/storefinder/core/store/reducers/index.ts:L21-L29, core-libs/core/src/state/utils/loader/loader.reducer.ts:L32-L60, core-libs/core/src/state/utils/loader/loader.reducer.ts:L80-L84).

- **T12 — due** `STORE_FINDER_FEATURE`. `'storeFinder'` (root, nome feature lazy) e `'stores'` (core, chiave NgRx) (feature-libs/storefinder/root/feature-name.ts:L7-L7, feature-libs/storefinder/core/store/store-finder-state.ts:L10-L10).
- **T13 — metodi deprecati assenti dal proxy.** `getStoreLatitude`/`getStoreLongitude`/`getDirections` non sono in `methods`: chiamati sul facade lazy non esistono (feature-libs/storefinder/root/facade/store-finder.facade.ts:L28-L39, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L120-L123). Il ramo legacy dei marker, `AbstractStoreItemComponent` e `StoreFinderListComponent` li usano ancora tramite `StoreFinderService` (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L255-L258, feature-libs/storefinder/components/abstract-store-item/abstract-store-item.component.ts:L17-L19, feature-libs/storefinder/components/store-finder-search-result/store-finder-list/store-finder-list.component.ts:L89-L92).
- **T14 — array vuoto.** `renderMap` accede a `locations[0]` senza controllo: `Object.entries(undefined)` lancia (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L58-L60).
- **T15 — due** `#storeMap`. Il template della lista ha una mappa desktop e una mobile con lo stesso riferimento; `@ViewChild('storeMap')` ne prende una sola (feature-libs/storefinder/components/store-finder-search-result/store-finder-list/store-finder-list.component.html:L59-L59, feature-libs/storefinder/components/store-finder-search-result/store-finder-list/store-finder-list.component.html:L141-L141, feature-libs/storefinder/components/store-finder-search-result/store-finder-list/store-finder-list.component.ts:L58-L59).
- **T16 — subscription sovrascritta.** `reloadStoreEntitiesOnContextChange` assegna `this.subscription =` sopra l'istanza del field initializer (feature-libs/storefinder/core/facade/store-finder.service.ts:L31-L31, feature-libs/storefinder/core/facade/store-finder.service.ts:L193-L193).
- **T17 — filtro per paese lato client** dopo una ricerca con `pageSize: -1` (feature-libs/storefinder/core/store/effects/find-stores.effect.ts:L40-L48, feature-libs/storefinder/core/facade/store-finder.service.ts:L215-L224).
- **T18 —** `currentPage: 0` **non inviato** perché falsy (feature-libs/storefinder/occ/adapters/occ-store-finder.adapter.ts:L93-L95).
- **T19 — SSR.** `reloadStoreEntitiesOnContextChange` gira solo in browser (feature-libs/storefinder/core/facade/store-finder.service.ts:L192-L192); il callback Google async non viene registrato senza `defaultView` (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L132-L140).
- **T20 — stile schedule.** Placeholder/allowlist `cx-store-finder-schedule`, ma il componente ha selector `cx-schedule` (feature-libs/storefinder/styles/components/_store-finder-schedule.scss:L1-L1, feature-libs/storefinder/components/schedule-component/schedule.component.ts:L16-L16).

Pickup in store

- **T21 — selector duplicato.** `PdpPickupOptionsContainerComponent` ha lo stesso selector `cx-cart-pickup-options-container` del container carrello (feature-libs/pickup-in-store/components/container/pdp-pickup-options-container/pdp-pickup-options-container.component.ts:L57-L57, feature-libs/pickup-in-store/components/container/cart-pickup-options-container/cart-pickup-options-container.component.ts:L79-L79).
- **T22 —** `pickupOption$` **assegnato in un** `tap`: esiste solo dopo che la subscription combinata ha emesso (feature-libs/pickup-in-store/components/container/pdp-pickup-options-container/pdp-pickup-options-container.component.ts:L94-L98, feature-libs/pickup-in-store/components/container/pdp-pickup-options-container/pdp-pickup-options-container.component.ts:L131-L145).
- **T23 —** `catchError` **che restituisce il creator.** In `setDefaultPointOfService$` il `catchError` emette `LoadDefaultPointOfService` non invocato; il `map` finale maschera il bug emettendo sempre `LoadDefaultPointOfService()` (feature-libs/pickup-in-store/core/store/effects/default-point-of-service-name.effect.ts:L100-L105).

- **T24 —** `tap` **no-op** che restituisce un oggetto (feature-libs/pickup-in-store/core/services/preferred-store.service.ts:L90-L93).
- **T25 —** `clearPreferredStore` rimuove solo la chiave localStorage, non lo stato NgRx né il profilo (feature-libs/pickup-in-store/core/services/preferred-store.service.ts:L64-L66).
- **T26 —** `lowStock` **= non disponibile**: "nascondi esauriti" nasconde anche i negozi con stock basso (feature-libs/pickup-in-store/core/utils/utils.ts:L9-L15).
- **T27 — un solo negozio per prodotto** in `stockLevelAtStore` (feature-libs/pickup-in-store/core/store/reducers/stock/stock-level.reducer.ts:L47-L50).
- **T28 — effetto senza** `catchError`**.** Un errore HTTP in `loadStockLevelAtStore$` arriva al default error handler di NgRx, che risottoscrive l'effetto fino a 10 volte e poi lo lascia terminare (feature-libs/pickup-in-store/core/store/effects/stock.effect.ts:L51-L65, deps:ngrx-effects-21.0.1/package/fesm2022/ngrx-effects.mjs:L174-L184).
- **T29 —** `ClearStockData` **azzera tutto**, compresi `hideOutOfStock` e `browserLocation` (feature-libs/pickup-in-store/core/store/reducers/stock/index.ts:L42-L52).
- **T30 — codice morto.** Azioni definite ma non usate fuori dal file (`SET_PICKUP_OPTION_TO_DELIVERY*`, `SET_PICKUP_OPTION_TO_PICKUP_IN_STORE*`, `StockLevelOnHold`, …) e config `pickupInStore.consentTemplateId` senza lettori (feature-libs/pickup-in-store/core/store/actions/pickup-location.action.ts:L22-L33, feature-libs/pickup-in-store/core/store/actions/stock.action.ts:L35-L41, feature-libs/pickup-in-store/core/config/default-pickup-in-store-config.ts:L10-L12).
- **T31 — geolocalizzazione negata** nel dialog: `useMyLocation` non passa una error callback, lo spinner resta attivo (feature-libs/pickup-in-store/components/container/store-search/store-search.component.ts:L49-L57, feature-libs/pickup-in-store/components/services/current-location.service.ts:L28-L38).
- **T32 — subscription accumulate.** Ogni `onPickupOptionChange('pickup')` aggiunge una subscription a `storeDetails$` attiva fino al destroy (possibili `updateEntry` ripetuti) (feature-libs/pickup-in-store/components/container/cart-pickup-options-container/cart-pickup-options-container.component.ts:L270-L288); analogamente `MyPreferredStoreComponent` sottoscrive senza unsubscribe (feature-libs/pickup-in-store/components/container/my-preferred-store/my-preferred-store.component.ts:L118-L163).
- **T33 —** `take(1)` **dopo** `combineLatest` con `filter(!!details)` in `PickupInfoContainerComponent`: se un negozio non carica mai, non emette nulla (feature-libs/pickup-in-store/components/container/pickup-info-container/pickup-info-container.component.ts:L45-L66).
- **T34 — outlet** `PICKUP_INFO` **mai renderizzato.** Il pickup registra un REPLACE su `CartOutlets.PICKUP_INFO`, ma nessun template del repo lo rende con `cxOutlet` (grep): il container non compare a meno che l'app non aggiunga l'outlet (feature-libs/cart/base/root/models/cart-outlets.model.ts:L21-L21, feature-libs/pickup-in-store/components/container/pickup-info-container/pickup-info-container.module.ts:L19-L23).
- **T35 —** `RemoveLocation` non cancella la chiave ma la imposta a `{pickupOption: 'delivery'}` (feature-libs/pickup-in-store/core/store/reducers/pickup-locations/pickup-locations.reducer.ts:L20-L23).
- **T36 — profilo utente anonimo.** `loadDefaultPointOfService$` ricade sul localStorage se `userProfileService.get()` non ha `defaultPointOfServiceName` (feature-libs/pickup-in-store/core/store/effects/default-point-of-service-name.effect.ts:L42-L60). DA VERIFICARE cosa emetta `get()` per l'utente anonimo: non verificato in `@spartacus/user/profile`.

10. Come fare debug

1. **Redux DevTools**: cercare le chiavi `stores`, `pickup-locations`, `pickup-option`, `stock` (feature-libs/storefinder/core/store/store-finder-state.ts:L10-L10, feature-libs/pickup-in-store/core/store/pickup-in-store-store.module.ts:L29-L53). Per lo store finder controllare `findStores.loading/success` *e* `viewAllStores.loading/success` insieme (T11). Le azioni hanno prefisso `[StoreFinder]` (feature-libs/storefinder/core/store/store-finder-state.ts:L11-L11).
2. **La feature è caricata?** RDD/pickup/storefinder sono lazy: i facade risolvono la feature al primo metodo chiamato (core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L49-L56). Nel tab Network si vede il chunk; per pickup deve comparire *prima* del chunk add-to-cart/cart (dipendenze in feature-libs/pickup-in-store/root/pickup-in-store-root.module.ts:L42-L57).
3. **L'outlet appare?** Verificare che il template ospite renda l'id (`cx-delivery-mode`, `cx-order-overview`, `cx-cart-item.details`, `cx-cart-item.delivery-details`, `cx-add-to-cart-pickup-option`) (feature-libs/cart/base/root/models/cart-outlets.model.ts:L10-L31). Ricordare T34 per `cx-pickup-info`.
4. **EDD non mostra nulla**: nel Network la risposta del cart deve contenere `arrivalSlots` dentro `entries`; se manca, l'endpoint effettivo non è quello EDD (sezione 3.2, T8). Si può ispezionare la config con `inject(OccConfig)`/`Config` dal debugger.
5. **RDD**: nel Network la richiesta `PUT …/requestedretrievaldate?requestedRetrievalAt=…`; il body conterrà `{"headers":…}` (T1). Breakpoint in `setRequestedDeliveryDate` del componente per vedere quale guard la fa uscire (feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L134-L145).
6. **Mappa vuota**: in dev mode compare il warning "A Google Maps api key is required..." se manca la chiave (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L49-L56); con il toggle async cercare su `window` la funzione `__spartacusGoogleMapsInit_<n>` (feature-libs/storefinder/core/service/google-map-renderer.service.ts:L130-L139).
7. **Negozio preferito**: in DevTools → Application → Local Storage la chiave `preferred_store` (feature-libs/pickup-in-store/root/pickup-in-store-constants.ts:L7-L8); nello stato `pickup-locations.defaultPointOfService`.
8. **Pickup ↔ delivery nel carrello**: osservare se parte un `PUT` (verso delivery) o un `PATCH` con `deliveryPointOfService` (verso pickup) su `updateEntries` (feature-libs/cart/base/occ/adapters/occ-cart-entry.adapter.ts:L86-L104).
9. **Test unitari** delle lib: `nx test-vitest <library>` o `npx vitest run --config feature-libs/pickup-in-store/vitest.config.ts <spec>` (le lib hanno `vitest.config.ts`, vedi mappa nel dossier; `node_modules` non è installato in questo ambiente, quindi non eseguito qui).

11. Domande di autoverifica

1. **Perché i componenti RDD stanno nell'entry point `root` e non nel modulo lazy?** Perché sono registrati con `provideOutlet` nel root module eager, che richiede la classe del componente; il modulo lazy contiene solo core + OCC. — feature-libs/requested-delivery-date/root/requested-delivery-date-root.module.ts:L35-L50, feature-libs/requested-delivery-date/root/public_api.ts:L7-L11, feature-libs/requested-delivery-date/requested-delivery-date.module.ts:L11-L14.
2. **Cosa succede quando l'utente apre lo step delivery mode con un carrello senza data richiesta?** Il picker imposta la data a `earliestRetrievalAt` e chiama subito il backend con un `PUT`; al successo ricarica i delivery mode supportati. — feature-libs/requested-delivery-date/root/components/delivery-mode-

date-picker/delivery-mode-date-picker.component.ts:L84-L99, feature-libs/requested-delivery-date/root/components/delivery-mode-date-picker/delivery-mode-date-picker.component.ts:L146-L158.

3. **Perché l'header** `USE_CLIENT_TOKEN` **dell'adapter RDD non ha effetto?** Perché gli header sono passati come secondo argomento di `put`, che è il body. — feature-libs/requested-delivery-date/occ/adapters/occ-requested-delivery-date.adapter.ts:L43-L43, angular:packages/common/http/src/client.ts:L4451-L4454.
4. **Come fa EDD a ottenere** `arrivalSlots` **dal backend senza toccare la cart lib?** Fornisce una default config che ridefinisce gli endpoint `carts`/`cart`/`createCart` con `arrivalSlots` nei fields; le default chunk sono fuse in ordine con `deepMerge`. — feature-libs/estimated-delivery-date/show-estimated-delivery-date/show-estimated-delivery-date.module.ts:L28-L29, feature-libs/estimated-delivery-date/show-estimated-delivery-date/config/default-occ-cart-with-edd.config.ts:L10-L28, core-libs/core/src/config/services/configuration.service.ts:L76-L100.
5. **Perché nello store finder una ricerca può far apparire "in caricamento" anche la vista dei conteggi?** Perché i due sotto-stati usano `loaderReducer` con lo stesso entity type `STORE_FINDER_DATA`. — feature-libs/storefinder/core/store/reducers/index.ts:L21-L29, core-libs/core/src/state/utils/loader/loader.reducer.ts:L32-L44.
6. **Cosa succede ai risultati dello store finder dopo un cambio lingua?** L'effetto emette `ClearStoreFinderData`, il meta reducer azzera lo stato, `viewAllStores$` ricarica i conteggi e `StoreFinderService` ricarica per country/store dai route params. — feature-libs/storefinder/core/store/effects/view-all-stores.effect.ts:L28-L68, feature-libs/storefinder/core/store/reducers/index.ts:L39-L53, feature-libs/storefinder/core/facade/store-finder.service.ts:L191-L213.
7. **Che valore usare per vedere la mappa senza chiave Google in sviluppo, e cosa viene inviato?** `GOOGLE_MAPS_DEVELOPMENT_KEY_CONFIG` (`'cx-development'`); al caricamento lo script riceve `key` vuota. — feature-libs/storefinder/root/config/constants.ts:L7-L7, feature-libs/storefinder/core/service/google-map-renderer.service.ts:L82-L85, projects/storefrontapp/src/app/private/private.providers.ts:L46-L49.
8. **Come garantisce pickup-in-store che i suoi outlet REPLACE siano registrati quando si apre il PDP o il carrello?** Si dichiara dipendenza delle feature `ADD_TO_CART_FEATURE` e `CART_BASE_FEATURE`, così viene caricato prima di esse. — feature-libs/pickup-in-store/root/pickup-in-store-root.module.ts:L39-L60.
9. **Come arriva il negozio scelto sul PDP fino alla richiesta di add to cart?** La selezione nel dialog imposta l'intended location con `pickupOption: 'pickup'`; `AddToCartComponent` legge `intendedPickupLocation$` dal componente in outlet (via `cxComponentRef`) e passa il nome a `addEntry`. — feature-libs/pickup-in-store/components/container/store-list/store-list.component.ts:L67-L76, feature-libs/cart/base/components/add-to-cart/add-to-cart.component.ts:L267-L287.
10. **Quale chiamata HTTP parte quando nel carrello si passa da pickup a delivery, e viceversa?** Verso delivery: `PUT` con sola `quantity`; verso pickup: `PATCH` con `deliveryPointOfService.name`. — feature-libs/pickup-in-store/components/container/cart-pickup-options-container/cart-pickup-options-container.component.ts:L255-L289, feature-libs/cart/base/occ/adapters/occ-cart-entry.adapter.ts:L86-L104.

TAVOLA 32.1 **4.1 RDD: dal delivery mode al backend**

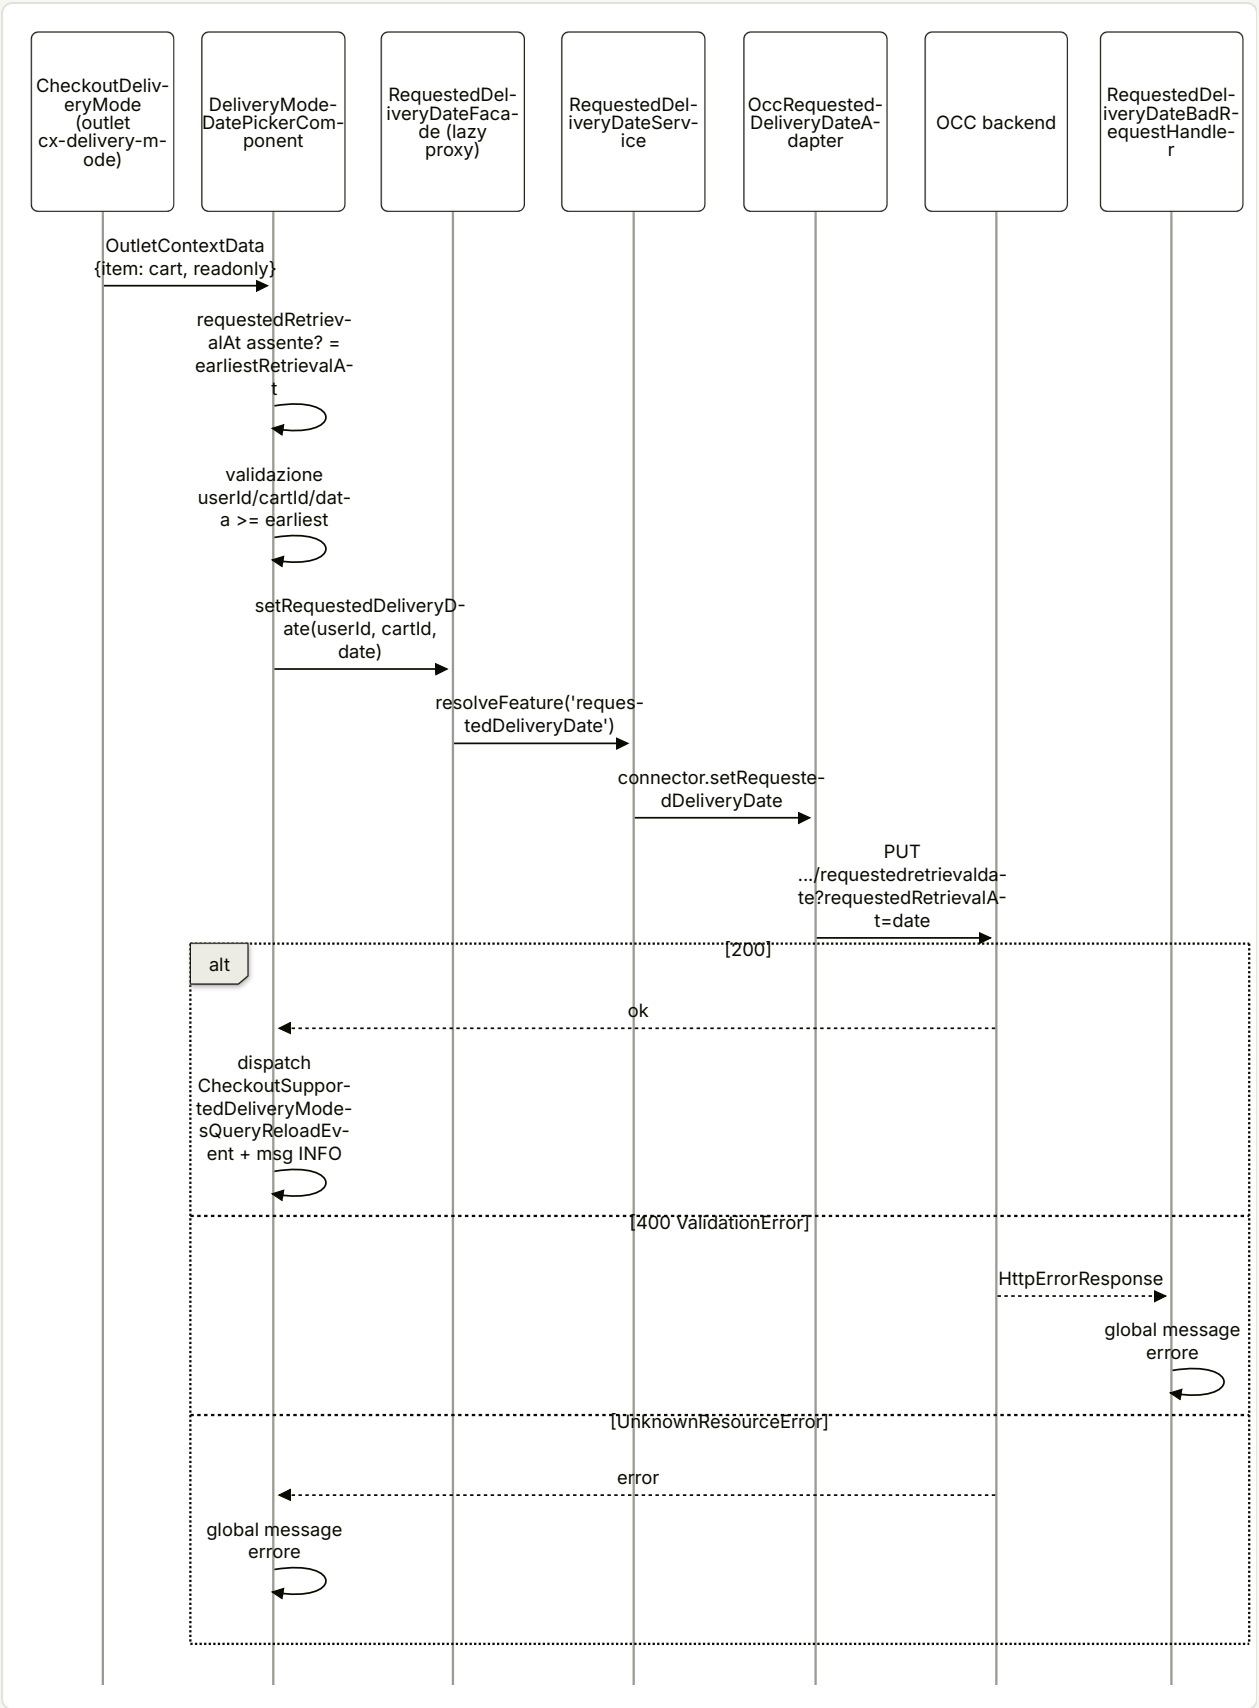

TAVOLA 32.2 **4.2 Store finder: ricerca e cambio contesto**

1. A cosa serve e perché esiste

Questo capitolo raccoglie tre librerie opzionali di `feature-libs/` che hanno una cosa in comune: **non aggiungono funzionalità di commercio**, ma collegano lo storefront a sistemi esterni che osservano o modificano la pagina dall'esterno. Sono:

LIBRERIA	ENTRY POINT	SISTEMA ESTERNO	MECCANISMO SPARTACUS USATO
`@spartacus/tracking`	`tms/core`, `tms/gtm`, `tms/aep`, `personalization`, `personalization/root`, `personalization/core`	Google Tag Manager, Adobe Experience Platform Launch, personalizzazione SAP Commerce	`EventService`, `APP_INITIALIZER`, `HTTP_INTERCEPTORS`, feature CMS lazy
`@spartacus/smartedit`	`smartedit`, `smartedit/root`, `smartedit/core`	SAP SmartEdit (editor WYSIWYG del CMS)	`APP_INITIALIZER`, `HTTP_INTERCEPTORS`, `ComponentDecorator`/`SlotDecorator`, `FeatureModulesService`
`@spartacus/qualtrics`	`qualtrics`, `qualtrics/root`, `qualtrics/components`	Qualtrics Site Intercept (QSI)	componente CMS lazy + `ScriptLoader`

Le tre librerie riusano in modo esemplare i meccanismi descritti nei capitoli precedenti, ed è per questo che vale la pena leggerle anche se non si usa nessuno dei prodotti esterni:

- **Tracking/TMS** è il consumatore "canonico" del bus eventi: un servizio root si sottoscrive, all'avvio dell'app, a un elenco di classi `CxEvent` scelto in configurazione e inoltra ogni evento a un *collector* che scrive nel data layer della pagina (`feature-libs/tracking/tms/core/services/tms.service.ts:L46-L96`). Il bus eventi è descritto in 20 — Facade, command & query, eventi.
- **Personalization** lavora a livello HTTP: due interceptor fanno da "cookie applicativo", rimandando al backend OCC gli header `Occ-Personalization-Id` / `Occ-Personalization-Time` che il backend stesso ha restituito, persistiti in `localStorage` (`feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L66-L97`). Un servizio separato decodifica il *contesto di personalizzazione* (segmenti e azioni) da un componente CMS nascosto (`feature-libs/tracking/personalization/core/services/personalization-context.service.ts:L30-L69`).
- **SmartEdit** è l'esempio più completo di integrazione "a strati": un root module sempre caricato decide all'avvio se l'app gira dentro l'iframe di SmartEdit (`feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L61-L72`), e solo in quel caso carica lazy il modulo che **decora** ogni slot e componente CMS con il "contratto" HTML richiesto da SmartEdit (`feature-libs/smartedit/core/services/smart-edit.service.ts:L158-L191`) ed espone su `window.smartedit` le callback di re-render (`feature-libs/smartedit/core/services/smart-edit.service.ts:L38-L52`).
- **Qualtrics** è la più piccola: un componente CMS senza template che inserisce lo script di deployment Qualtrics e un servizio che, all'evento `qsi_js_loaded`, invoca l'API QSI (`feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L55-L139`).

Tutte e tre seguono la convenzione root/lazy di Spartacus spiegata in 12 — Feature module e lazy loading: un `*RootModule` piccolo importato eagerly che registra configurazione di default, interceptor o `featureModules`, e un modulo pesante caricato on demand tramite `featureModules.<nome>.module`. La demo app le importa tutte e tre incondizionatamente (`projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L263-L272`).

2. Mappa dei file

2.1 feature-libs/tracking

PATH	RUOLO
feature-libs/tracking/public_api.ts	entry radice vuota (export {};)
feature-libs/tracking/tms/public_api.ts	entry tms vuota
feature-libs/tracking/tms/core/base-tms.module.ts	BaseTmsModule.forRoot() + tmsFactory (APP_INITIALIZER)
feature-libs/tracking/tms/core/config/tms-config.ts	TmsConfig, TmsCollectorConfig, TmsCollectors + augmentation di Config
feature-libs/tracking/tms/core/model/tms.model.ts	interfacce TmsCollector, WindowObject
feature-libs/tracking/tms/core/services/tms.service.ts	TmsService: sottoscrive gli eventi e invoca i collector
feature-libs/tracking/tms/core/public_api.ts	API @spartacus/tracking/tms/core (+ TmsCollectors augmentabile)
feature-libs/tracking/tms/gtm/gtm.module.ts	GtmModule: solo default config
feature-libs/tracking/tms/gtm/config/default-gtm.config.ts	GtmCollectorConfig, defaultGoogleTagManagerConfig, augmentation gtm
feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts	GtmCollectorService: snippet GTM, push su array
feature-libs/tracking/tms/aep/aep.module.ts	AepModule: solo default config
feature-libs/tracking/tms/aep/config/default-aep.config.ts	AepCollectorConfig, defaultAdobeExperiencePlatformConfig, augmentation aep
feature-libs/tracking/tms/aep/services/aep-collector.service.ts	AepCollectorService: script Launch, merge su oggetto
feature-libs/tracking/personalization/root/personalization-root.module.ts	interceptor + default config + feature CMS personalization
feature-libs/tracking/personalization/root/config/personalization-config.ts	PersonalizationConfig
feature-libs/tracking/personalization/root/config/default-personalization-config.ts	default (disabilitata, nomi header, contesto)
feature-libs/tracking/personalization/root/feature-name.ts	PERSONALIZATION_FEATURE
feature-libs/tracking/personalization/root/http-interceptors/index.ts	array interceptors (Id, poi Time)
feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts	header + localStorage personalization-id
feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-time.interceptor.ts	header + localStorage personalization-time
feature-libs/tracking/personalization/root/public_api.ts	API .../personalization/root
feature-libs/tracking/personalization/personalization.module.ts	PersonalizationModule (entry lazy) → importa PersonalizationCoreModule

PATH	RUOLO
feature-libs/tracking/personalization/core/personalization-core.module.ts	PersonalizationCoreModule: @NgModule({}) vuoto
feature-libs/tracking/personalization/core/services/personalization-context.service.ts	PersonalizationContextService: decodifica il contesto dal CMS
feature-libs/tracking/personalization/core/model/personalization-context.model.ts	PersonalizationContext, PersonalizationAction
feature-libs/tracking/schematics/add-tracking/index.ts	addTrackingFeatures (ng-add)
feature-libs/tracking/vitest.config.ts	configurazione Vitest e soglie di coverage

2.2 feature-libs/smartedit

PATH	RUOLO
feature-libs/smartedit/smart-edit.module.ts	SmartEditModule (entry lazy @spartacus/smartedit)
feature-libs/smartedit/root/smart-edit-root.module.ts	interceptor + default config + APP_INITIALIZER (smartEditFactory)
feature-libs/smartedit/root/config/smart-edit-config.ts	SmartEditConfig
feature-libs/smartedit/root/config/default-smart-edit-config.ts	default cx-preview / localhost:9002
feature-libs/smartedit/root/feature-name.ts	SMART_EDIT_FEATURE
feature-libs/smartedit/root/services/smart-edit-launcher.service.ts	SmartEditLauncherService: rileva SmartEdit, gestisce cmsTicketId, carica injector e feature
feature-libs/smartedit/root/http-interceptors/cms-ticket.interceptor.ts	CmsTicketInterceptor: aggiunge cmsTicketId alle chiamate OCC
feature-libs/smartedit/root/http-interceptors/index.ts	provider HTTP_INTERCEPTORS
feature-libs/smartedit/core/smart-edit-core.module.ts	SmartEditCoreModule: decoratori + avvio processCmsPage()
feature-libs/smartedit/core/services/smart-edit.service.ts	SmartEditService: contratto HTML, preview page, re-render
feature-libs/smartedit/core/decorators/index.ts	smartEditDecorators (multi provider)
feature-libs/smartedit/core/decorators/smart-edit-component-decorator.ts	SmartEditComponentDecorator
feature-libs/smartedit/core/decorators/smart-edit-slot-decorator.ts	SmartEditSlotDecorator
feature-libs/smartedit/assets/webApplicationInjector.js	script SmartEdit minificato ("Version: 0.0.5"), pubblicato come asset
feature-libs/smartedit/schematics/add-smartedit/index.ts	addSmartEditFeatures (ng-add)

2.3 feature-libs/qualtrics

PATH	RUOLO
feature-libs/qualtrics/qualtrics.module.ts	QualtricsModule (entry lazy @spartacus/qualtrics)

PATH	RUOLO
feature-libs/qualtrics/root/qualtrics-root.module.ts	feature CMS `qualtrics` → `QualtricsComponent`
feature-libs/qualtrics/root/feature-name.ts	`QUALTRICS_FEATURE`
feature-libs/qualtrics/components/qualtrics-components.module.ts	mapping CMS dei due componenti + `defaultQualtricsConfig`
feature-libs/qualtrics/components/qualtrics-loader/qualtrics.component.ts	`cx-qualtrics`: inserisce lo script di deployment
feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts	`QualtricsLoaderService`: integrazione QSI
feature-libs/qualtrics/components/qualtrics-loader/config/qualtrics-config.ts	`QualtricsConfig`
feature-libs/qualtrics/components/qualtrics-loader/config/default-qualtrics-config.ts	`{ qualtrics: {} }`
feature-libs/qualtrics/components/qualtrics-embedded-feedback/qualtrics-embedded-feedback.component.ts	`cx-qualtrics-embedded-feedback`: componente vuoto
feature-libs/qualtrics/styles/_qualtrics-embedded-feedback.scss	stile placeholder
feature-libs/qualtrics/schematics/add-qualtrics/index.ts	`addQualtricsFeatures` (ng-add)

2.4 Codice di core usato dalle tre librerie

PATH	RUOLO NEL CAPITOLO
core-libs/core/src/event/event.service.ts	`EventService.get()` fornisce gli stream che il TMS sottoscrive
core-libs/core/src/util/script-loader.service.ts	`ScriptLoader.embedScript()` usato da AEP, SmartEdit e Qualtrics
core-libs/core/src/cms/decorators/component-decorator.ts, core-libs/core/src/cms/decorators/slot-decorator.ts	classi astratte implementate da SmartEdit
core-libs/core/src/cms/services/dynamic-attribute.service.ts	applica tutti i decoratori a slot e componenti
core-libs/core/src/lazy-loading/unified-injector.ts	trova i decoratori anche nei moduli lazy
core-libs/core/src/lazy-loading/feature-modules.service.ts	`resolveFeature()` usato dal launcher SmartEdit
core-libs/core/src/cms/facade/cms.service.ts	`clearComponentState`, `refreshPageById`, `refreshLatestPage`, `refreshComponent`
core-libs/storefront/cms-structure/services/cms-features.service.ts	mappa componente CMS → feature lazy (Personalization, Qualtrics)
projects/storefrontapp/src/app/spartacus/features/tracking/personalization-feature.module.ts	configurazione demo di TMS e personalization
projects/storefrontapp/src/app/spartacus/features/smartedit/smartedit-feature.module.ts	configurazione demo SmartEdit
projects/storefrontapp/src/app/spartacus/features/qualtrics/qualtrics-feature.module.ts	configurazione demo Qualtrics

File aggiuntivi

PATH	RUOLO
feature-libs/qualtrics/_index.scss	entry SCSS: importa @spartacus/styles/scss/core e ./styles/index
feature-libs/qualtrics/public_api.ts	entry point primario @spartacus/qualtrics: riesporta qualtrics.module
feature-libs/qualtrics/vitest.config.ts	configurazione Vitest di qualtrics (jsdom, coverage v8, nessun alias)
feature-libs/smartedit/public_api.ts	entry point primario @spartacus/smartedit: riesporta smart-edit.module
feature-libs/smartedit/vitest.config.ts	configurazione Vitest di smartedit (alias verso mock-window-ref)

3. Come funziona passo per passo

3.1 TMS: dalla configurazione all'avvio

1. **Import.** L'app importa `BaseTmsModule.forRoot()` più uno o più moduli vendor (`GtmModule`, `AepModule`) e fornisce un `TmsConfig` con gli eventi da tracciare. La demo lo fa in un unico `PersonalizationFeatureModule` (projects/storefrontapp/src/app/spartacus/features/tracking/personalization-feature.module.ts:L22-L39).
2. **Default del collector.** `GtmModule` e `AepModule` non hanno logica: forniscono solo una default config (feature-libs/tracking/tms/gtm/gtm.module.ts:L11-L14, feature-libs/tracking/tms/aep/aep.module.ts:L11-L14) che imposta `tagManager.gtm.collector = GtmCollectorService` (feature-libs/tracking/tms/gtm/config/default-gtm.config.ts:L20-L26) e `tagManager.aep.collector = AepCollectorService` (feature-libs/tracking/tms/aep/config/default-aep.config.ts:L20-L26). Nessun evento è attivo di default: gli `events` li decide l'app. Poiché default config e config dell'app vengono fuse (vedi 11 — Configurazione), nella config finale la voce `gtm` contiene sia il `collector` del default sia gli `events` dell'app.
3. **Tipi augmentabili.** `TmsConfig` è un `abstract class` con `useExisting: Config` e una sola proprietà `tagManager?: TmsCollectors` (feature-libs/tracking/tms/core/config/tms-config.ts:L38-L47), fusa nell'interfaccia `Config` di core per module augmentation (feature-libs/tracking/tms/core/config/tms-config.ts:L49-L51). `TmsCollectors` è un dizionario `[tms: string]: TmsCollectorConfig | undefined` (feature-libs/tracking/tms/core/config/tms-config.ts:L31-L33) che i pacchetti vendor estendono a loro volta: GTM aggiunge `gtm?: GtmCollectorConfig` con `gtmId` (feature-libs/tracking/tms/gtm/config/default-gtm.config.ts:L10-L18), AEP aggiunge `aep?: AepCollectorConfig` con `scriptUrl` (feature-libs/tracking/tms/aep/config/default-aep.config.ts:L10-L18). Per questo `TmsCollectors` è esportato dentro il blocco delimitato dai commenti AUGMENTABLE_TYPES_START/END del public API (feature-libs/tracking/tms/core/public_api.ts:L12-L14).
4. **`APP_INITIALIZER`.** `BaseTmsModule.forRoot()` registra un `APP_INITIALIZER` multi con factory `tmsFactory` e dipendenza `TmsService` (feature-libs/tracking/tms/core/base-tms.module.ts:L18-L33); la factory restituisce `() => service.collect()` (feature-libs/tracking/tms/core/base-tms.module.ts:L10-L16). Senza `forRoot()` il modulo è un `@NgModule({})` vuoto (feature-libs/tracking/tms/core/base-tms.module.ts:L18-L19): importare `BaseTmsModule` "nudo" non attiva nulla. Il token `APP_INITIALIZER` è deprecato da Angular v19 a favore di `provideAppInitializer` (angular:packages/core/src/application/application_init.ts:L38-L38); l'ordine degli initializer è trattato in 10 — Bootstrap e inizializzazione.
5. **Guardia SSR.** `collect()` esce subito se non si è nel browser (feature-libs/tracking/tms/core/services/tms.service.ts:L46-L49): in SSR nessun data layer è creato e nessuno script vendor inserito.
6. **Iterazione sui TMS.** `collect()` scorre con `for...in` le chiavi di `tagManager`, saltando le proprietà non proprie (feature-libs/tracking/tms/core/services/tms.service.ts:L51-L54). Una voce senza `collector`

viene saltata con warning in dev mode (feature-libs/tracking/tms/core/services/tms.service.ts:L59-L66).

7. **Stream eventi.** Per ogni classe in `events` ottiene lo stream con `eventsService.get(event)`; senza `events` la lista è vuota (feature-libs/tracking/tms/core/services/tms.service.ts:L68-L70). `EventService.get` restituisce l'`output$` del *merging subject* del tipo, validato in dev mode (core-libs/core/src/event/event.service.ts:L90-L96).
8. **Istanza e `init`.** Il collector è ottenuto con `this.injector.get(collectorConfig.collector)` — l'`Injector` iniettato in `TmsService`, che è `providedIn: 'root'` (feature-libs/tracking/tms/core/services/tms.service.ts:L27-L41) — e `init` è chiamato subito con `nativeWindow!` (feature-libs/tracking/tms/core/services/tms.service.ts:L71-L75).
9. **Push.** Gli stream sono uniti da `mapEvents` (protected) con `merge(...events)` (feature-libs/tracking/tms/core/services/tms.service.ts:L104-L108). A ogni evento: log con emoji 🎤 se `debug`, poi `collector.map?.(event) ?? event`, poi `collector.pushEvent(config, window, event)`; la subscription è accumulata in `this.subscription` (feature-libs/tracking/tms/core/services/tms.service.ts:L77-L94) e chiusa in `ngOnDestroy` (feature-libs/tracking/tms/core/services/tms.service.ts:L113-L115).

3.2 I due collector: GTM e AEP a confronto

ASPETTO	GTMCOLLECTORSERVICE	AEPCOLLECTORSERVICE
Dipendenza iniettata	`WindowRef` (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L19-L21)	`ScriptLoader` (feature-libs/tracking/tms/aep/services/aep-collector.service.ts:L19-L21)
Nome data layer di default	`'dataLayer'` (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L26-L26)	`'digitalData'` (feature-libs/tracking/tms/aep/services/aep-collector.service.ts:L26-L26)
Tipo del data layer	array, `?? []` (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L27-L27)	oggetto, `?? {}` (feature-libs/tracking/tms/aep/services/aep-collector.service.ts:L27-L27)
Caricamento script vendor	solo con `gtmId`: snippet GTM inline che inserisce `gtm.js` prima del primo `<script>` (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L29-L51)	solo con `scriptUrl`: `scriptLoader.embedScript({ src })` (feature-libs/tracking/tms/aep/services/aep-collector.service.ts:L29-L31)
`pushEvent`	`window[dataLayer].push(event)` (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L55-L62)	sostituzione con spread shallow `{ ...precedente, ...event }` (feature-libs/tracking/tms/aep/services/aep-collector.service.ts:L34-L44)
`map`	non implementato	non implementato

Dettagli dello snippet GTM: prima pusha `{ 'gtm.start': <timestamp>, event: 'gtm.js' }` nel data layer (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L38-L38), poi crea un `<script async>` con `src = 'https://www.googletagmanager.com/gtm.js?id=' + gtmId` e, se il data layer non si chiama `dataLayer`, aggiunge `&l=<nome>` (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L41-L43), infine lo inserisce prima del primo `<script>` del documento (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L39-L44).

Per AEP, `ScriptLoader.embedScript` crea un `<script async defer>`, non duplica uno script già presente (controllo fatto solo nel browser) e lo appende a `head` per default (core-libs/core/src/util/script-loader.service.ts:L55-L68, core-libs/core/src/util/script-loader.service.ts:L91-L93).

3.3 Personalization: gli interceptor degli header OCC

1. **Registrazione.** `PersonalizationRootModule` aggiunge l'array `interceptors`, la default config e una default config factory per la feature CMS (feature-libs/tracking/personalization/root/personalization-root.module.ts:L30-L37). Gli interceptor sono provider `HTTP_INTERCEPTORS` multi con `useExisting`, nell'ordine Id

→ Time (feature-libs/tracking/personalization/root/http-interceptors/index.ts:L13-L24). Angular costruisce la catena con `reduceRight`, quindi il primo registrato è il più esterno (angular:packages/common/http/src/interceptor.ts:L233-L240; vedi 06 — HttpClient e interceptor).

2. **Default.** `personalization.enabled` è `false`, gli header sono `Occ-Personalization-Id` e `Occ-Personalization-Time`, il contesto si trova nello slot `PlaceholderContentSlot` nel componente `PersonalizationScriptComponent` (feature-libs/tracking/personalization/root/config/default-personalization-config.ts:L9-L21). La forma della config è definita in `PersonalizationConfig` (feature-libs/tracking/personalization/root/config/personalization-config.ts:L10-L30).
3. **Costruzione dell'interceptor (solo browser).** `enabled = (localStorage && personalization.enabled) || false` (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L34-L37). Se abilitato, il nome header è messo in minuscolo e l'id iniziale letto dalla chiave `personalization-id` di `localStorage` (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L39-L49, chiave a feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L25-L25). Se disabilitato e c'è un id residuo, viene **rimosso** (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L50-L54): spegnere la feature pulisce lo storage al successivo avvio.
4. **Richiesta.** Se disabilitato, la richiesta passa invariata (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L62-L64). Altrimenti l'header è aggiunto solo se nome e valore sono noti e l'URL contiene `occEndpoints.getBaseUrl()` (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L66-L76).
5. **Risposta.** Su `HttpResponse`, se l'header compare fra `event.headers.keys()` e differisce dal valore in memoria, il nuovo valore è salvato in memoria e in `localStorage` (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L78-L97).
6. **Timestamp.** `OccPersonalizationTimeInterceptor` è identico ma usa la chiave `personalization-time` e `httpHeaderName.timestamp` (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-time.interceptor.ts:L25-L25, feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-time.interceptor.ts:L45-L49).

In pratica il backend assegna un id di personalizzazione alla prima risposta; lo storefront lo memorizza e lo rimanda a ogni chiamata OCC successiva, così il backend può riconoscere l'utente anonimo e applicare le stesse *customization*. DA VERIFICARE: che il backend emetta davvero questi header ed esponga il CORS `Access-Control-Expose-Headers` non è verificabile nel repo (dossier Q3).

3.4 Personalization: il contesto (segmenti e azioni)

1. **Feature CMS.** La default config factory associa la feature `personalization` al solo componente CMS `PersonalizationScriptComponent`, senza `module` (feature-libs/tracking/personalization/root/personalization-root.module.ts:L17-L28). Il `module` lo fornisce l'app: la demo punta a `import('@spartacus/tracking/personalization')` → `PersonalizationModule` (projects/storefrontapp/src/app/spartacus/features/tracking/personalization-feature.module.ts:L40-L48). `CmsFeaturesService` considera un componente "gestito da una feature" solo se la feature ha sia `module` sia `cmsComponents` (core-libs/storefront/cms-structure/services/cms-features.service.ts:L56-L76).
2. **Modulo lazy vuoto.** `PersonalizationModule` importa soltanto `PersonalizationCoreModule`, che è un `@NgModule({})` vuoto (feature-libs/tracking/personalization/personalization.module.ts:L10-L13, feature-libs/tracking/personalization/core/personalization-core.module.ts:L9-L10). Il vero codice di `core` è il servizio `PersonalizationContextService`, `providedIn: 'root'` (feature-libs/tracking/personalization/core/services/personalization-context.service.ts:L19-L28): viene istanziato da chi lo inietta, non dal caricamento del modulo.

3. **Lettura del contesto.** Senza `personalization.context`, `getPersonalizationContext()` restituisce `EMPTY` con warning in dev (feature-libs/tracking/personalization/core/services/personalization-context.service.ts:L30-L35). Altrimenti: pagina corrente → slot `context.slotPosition` → componente con `uid === context.componentId` → `properties.script.data` (feature-libs/tracking/personalization/core/services/personalization-context.service.ts:L37-L50).
4. **Decodifica.** Il payload è `JSON.parse(atob(data))`; poi ogni valore di ogni action e ogni segment è a sua volta decodificato base64 (feature-libs/tracking/personalization/core/services/personalization-context.service.ts:L54-L69). Il risultato ha la forma `{ actions: PersonalizationAction[]; segments: string[] }` (feature-libs/tracking/personalization/core/model/personalization-context.model.ts:L7-L19).
5. **Consumatore.** L'unico consumatore nel repo è `ProfileTagPushEventsService` di CDS, che combina ogni push event con `withLatestFrom(merge(of({segments: undefined, actions: undefined}), getPersonalizationContext()))` e scrive `segments`/`actions` in `item.data` (integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L98-L112). CDS è trattato in 34 — Integration libs: CDC, CDP, CDS.

3.5 SmartEdit: avvio e rilevamento

1. **Root module.** `SmartEditRootModule` registra `CmsTicketInterceptor`, la default config e un `APP_INITIALIZER` (`smartEditFactory`) che chiama `SmartEditLauncherService.load()` (feature-libs/smartedit/root/smartedit-root.module.ts:L13-L34). Default: `storefrontPreviewRoute: 'cx-preview'`, `allowOrigin: 'localhost:9002'` (feature-libs/smartedit/root/config/default-smart-edit-config.ts:L9-L14).
2. **Parse dell'URL.** `isLaunchedInSmartEdit()` separa `location.path()` su `?`, cerca il parametro che inizia con `cmsTicketId=` e ne prende il valore con `split('=')[1]` (feature-libs/smartedit/root/services/smartedit-launcher.service.ts:L61-L72).
3. **Pagina iniziale.** Se l'ultimo segmento del path è `storefrontPreviewRoute` **e** c'è un `cmsTicketId`, il ticket è persistito in `sessionStorage` (chiave `smartedit.cmsTicketId`) e memorizzato (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L74-L89, chiave a feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L27-L32).
4. **Fallback da sessionStorage.** Altrimenti il ticket viene ripristinato da `sessionStorage` e la sua sola presenza basta per considerarsi "in SmartEdit" — il caso d'uso dichiarato sono i redirect full-page, ad esempio il flusso OIDC di CDC (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L91-L96). Persistenza e ripristino sono saltati fuori dal browser, per evitare il `SecurityError` in SSR (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L98-L118).
5. **Caricamento.** Se in SmartEdit, `load()` risolve la feature `smartEdit` (lazy load di `SmartEditModule`) e inserisce lo script con `src: 'assets/webApplicationInjector.js'` (path relativo hardcoded) con `id: 'text/smartedit-injector'` e `data-smartedit-allow-origin` preso dalla config (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L43-L56). `ScriptLoader` usa `setAttribute` per le chiavi che iniziano con `data-` (e, solo con `disableKeyRestriction`, per quelle che non sono proprietà dello `<script>`); le altre diventano proprietà del DOM element. SmartEdit non passa `disableKeyRestriction`, quindi `id` diventa `script.id` (core-libs/core/src/util/script-loader.service.ts:L70-L82). Il file `webApplicationInjector.js` è minificato ("Version: 0.0.5") e fa parte degli asset pubblicati da ng-packagr (feature-libs/smartedit/assets/webApplicationInjector.js:L1-L2, feature-libs/smartedit/ng-package.json:L7-L11).
6. **`resolveFeature`.** `FeatureModulesService.resolveFeature` restituisce un errore "No module defined for Feature Module ..." se la feature non ha `module`; altrimenti risolve dipendenze e modulo con `shareReplay()` (core-libs/core/src/lazy-loading/feature-modules.service.ts:L42-L73). La demo configura `featureModules.smartEdit` con `import('@spartacus/smartedit')` → `SmartEditModule` (projects/storefrontapp/src/app/spartacus/features/smartedit/smartedit-feature.module.ts:L14-L27).

DA VERIFICARE: l'URL esatto con cui SmartEdit apre lo storefront (`.../cx-preview?cmsTicketId=...`) è dedotto dal parsing in feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L74-L89; il protocollo di `webApplicationInjector.js` non è leggibile (file minificato di terze parti).

3.6 SmartEdit: il `cmsTicketId` sulle chiamate OCC

`CmsTicketInterceptor` legge `service.cmsTicketId` dal launcher; se assente la richiesta passa invariata (feature-libs/smartedit/root/http-interceptors/cms-ticket.interceptor.ts:L29-L32). Altrimenti decide per sottostringa dell'URL:

- `/productList` → legge il `PageContext` corrente con `take(1)` e aggiunge `cmsTicketId` più `categoryCode = pageContext.id` se presente (feature-libs/smartedit/root/http-interceptors/cms-ticket.interceptor.ts:L33-L35, feature-libs/smartedit/root/http-interceptors/cms-ticket.interceptor.ts:L47-L72);
- `/cms/` o `/products/` → aggiunge il query param `cmsTicketId` (feature-libs/smartedit/root/http-interceptors/cms-ticket.interceptor.ts:L36-L42).

Il ticket permette al backend di restituire la versione *in anteprima* (staged) dei contenuti. L'interceptor è registrato multi con `useExisting` (feature-libs/smartedit/root/http-interceptors/index.ts:L11-L17). Poiché il root module è eager, l'interceptor è sempre nella catena, ma è un pass-through quando non c'è ticket.

3.7 SmartEdit: modulo lazy, decoratori e contratto HTML

1. **Lazy load.** `SmartEditModule` importa `SmartEditCoreModule` (feature-libs/smartedit/smart-edit.module.ts:L10-L13), che fornisce `smartEditDecorators` e nel costruttore chiama `smartEditService.processCmsPage()` (feature-libs/smartedit/core/smart-edit-core.module.ts:L11-L18).
2. **Decoratori multi.** `smartEditDecorators` registra `SmartEditComponentDecorator` su `ComponentDecorator` e `SmartEditSlotDecorator` su `SlotDecorator` (multi, `useExisting`) (feature-libs/smartedit/core/decorators/index.ts:L12-L23). Sono classi astratte di core con il solo metodo `decorate(element, renderer, data?)` (core-libs/core/src/cms/decorators/component-decorator.ts:L10-L23, core-libs/core/src/cms/decorators/slot-decorator.ts:L10-L23).
3. **Come i decoratori lazy arrivano al rendering.** `DynamicAttributeService` raccoglie i decoratori con `unifiedInjector.getMulti(...)` + `shareReplay(1)` (core-libs/core/src/cms/services/dynamic-attribute.service.ts:L24-L32). `UnifiedInjector.injectors$` parte dal root injector e aggiunge l'injector di ogni modulo lazy caricato, mentre `getMulti` accumula le istanze con `scan` (core-libs/core/src/lazy-loading/unified-injector.ts:L32-L35, core-libs/core/src/lazy-loading/unified-injector.ts:L79-L93). Così i provider di `SmartEditCoreModule` — che vive in un injector figlio — diventano visibili a un servizio root.
4. **Applicazione.** `PageSlotComponent` chiama `addAttributesToSlot` quando lo slot è presente (core-libs/storefront/cms-structure/page/slot/page-slot.component.ts:L157-L163); `ComponentWrapperDirective.decorate` chiama `addAttributesToComponent` (core-libs/storefront/cms-structure/page/component/component-wrapper.directive.ts:L138-L144). Entrambi i metodi leggono in modo sincrono (`getLastValueSync`) l'elenco dei decoratori e li invocano tutti (core-libs/core/src/cms/services/dynamic-attribute.service.ts:L40-L64). Il rendering CMS è descritto in 16 — CMS (storefront): rendering dinamico.
5. **Contratto.** Entrambi i decoratori passano `properties` del componente/slot a `addSmartEditContract` (feature-libs/smartedit/core/decorators/smart-edit-component-decorator.ts:L19-L31, feature-libs/smartedit/core/decorators/smart-edit-slot-decorator.ts:L19-L27). Il metodo itera i gruppi di `properties` (tipicamente `smartedit`): `classes` è splittata su spazi e applicata con `addClass`; ogni altra proprietà diventa un attributo `data-<gruppo>-<prop-in-kebab-case>` (feature-libs/smartedit/core/services/smart-edit.service.ts:L158-L191). Per esempio una proprietà `componentId` nel gruppo

`smartedit` diventa `data-smartedit-component-id` (trasformazione `split(/(?=[A-Z])/).join('-').toLowerCase()` a feature-libs/smartedit/core/services/smart-edit.service.ts:L178-L186).

6. **Contratto di pagina.** `processCmsPage()` attende il primo `BaseSite` non nullo, ne legge `defaultPreviewCategoryCode`/`defaultPreviewProductCode` (campi dichiarati in core-libs/core/src/model/misc.model.ts:L116-L121), poi per ogni pagina CMS corrente salva `pageId`, chiama `goToPreviewPage` e `addPageContract` (feature-libs/smartedit/core/services/smart-edit.service.ts:L55-L76). `addPageContract` crea un renderer per `body`, rimuove **tutte** le classi presenti sul `<body>` e applica il contratto da `cmsPage.properties` (feature-libs/smartedit/core/services/smart-edit.service.ts:L78-L94).
7. **Preview page.** `goToPreviewPage` agisce solo sulla prima pagina: se è `PRODUCT_PAGE` con `defaultPreviewProductCode` naviga a `cxRoute: 'product'`, se è `CATEGORY_PAGE` con `defaultPreviewCategoryCode` naviga a `cxRoute: 'category'` (feature-libs/smartedit/core/services/smart-edit.service.ts:L96-L121). Serve quando SmartEdit apre un *template* di pagina prodotto/categoria: lo storefront ha bisogno di un prodotto/categoria reale da mostrare.

3.8 SmartEdit: re-render dopo un edit

1. Il costruttore di `SmartEditService`, se esiste `nativeWindow`, crea `window.smartedit` ed espone `renderComponent` (delegato al metodo protected) e `reprocessPage` (feature-libs/smartedit/core/services/smart-edit.service.ts:L38-L52).
2. `renderComponent(componentId, componentType?, parentId?)` gira dentro `zone.run` — chiamato da codice esterno ad Angular, deve rientrare in zona per far scattare la change detection (vedi 04 — Change detection, zone e signals). Senza `parentId` si tratta di uno slot: svuota tutta la cache dei componenti e ricarica la pagina per `pageId` (o l'ultima pagina); con `parentId` e `componentType` ricarica il singolo componente. Restituisce sempre `true` (feature-libs/smartedit/core/services/smart-edit.service.ts:L126-L149).
3. Lato core: `clearComponentState()` senza argomenti cancella tutti i componenti in cache e dispatcha `ClearCmsComponent` per ciascuno, e il JSDoc cita proprio SmartEdit (core-libs/core/src/cms/facade/cms.service.ts:L296-L309); `refreshPageById` dispatcha `LoadCmsPageData({ id })`, `refreshLatestPage` usa il page context corrente, `refreshComponent` dispatcha `LoadCmsComponent` (core-libs/core/src/cms/facade/cms.service.ts:L197-L223). Lo store CMS è descritto in 15 — CMS (core).
4. `reprocessPage()` è vuoto con un `TODO: reprocess page API` (feature-libs/smartedit/core/services/smart-edit.service.ts:L151-L153).

3.9 Qualtrics

1. **Root.** `QualtricsRootModule` fornisce solo la default config factory che mappa la feature `qualtrics` sul componente CMS `QualtricsComponent` (feature-libs/qualtrics/root/qualtrics-root.module.ts:L11-L27). La demo aggiunge `module: () => import('@spartacus/qualtrics')` → `QualtricsModule` (projects/storefrontapp/src/app/spartacus/features/qualtrics/qualtrics-feature.module.ts:L14-L27).
2. **Lazy.** `QualtricsModule` importa `QualtricsComponentsModule` (feature-libs/qualtrics/qualtrics.module.ts:L10-L13), che importa i due componenti standalone, li mappa in `cmsComponents` e fornisce `defaultQualtricsConfig` (feature-libs/qualtrics/components/qualtrics-components.module.ts:L14-L35). Il default è `{ qualtrics: {} }`, cioè nessuno `scriptSource` (feature-libs/qualtrics/components/qualtrics-loader/config/default-qualtrics-config.ts:L9-L11).
3. **Componente.** `QualtricsComponent` (`cx-qualtrics`, template vuoto) nel **costruttore** chiama `qualtricsLoader.addScript(scriptSource)` se configurato, altrimenti warning in dev (feature-libs/qualtrics/components/qualtrics-loader/qualtrics.component.ts:L15-L33). Il JSDoc di `QualtricsConfig` suggerisce di tenere lo script di deployment negli asset locali (feature-libs/qualtrics/components/qualtrics-loader/config/qualtrics-config.ts:L10-L34).

4. **Service.** `QualtricsLoaderService` nel costruttore chiama `initialize()`, che sottoscrive `qsi$` e invoca `run()` a ogni emissione (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L77-L83, feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L113-L115). `qsiLoaded$` è `fromEvent(window, 'qsi_js_loaded')` solo nel browser, altrimenti `EMPTY` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L55-L58); `qsi$` passa per l'hook `isDataLoaded()`, prende `window.QSI`, filtra i falsy e salva in `qsiApi` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L66-L71).
5. `addScript`. Se lo script è già nel DOM (`script[src="..."]`) chiama `run(true)`, altrimenti lo inserisce con `scriptLoader.embedScript({ src })` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L91-L106). Il primo ramo (`run(true)`) copre la navigazione SPA: tornando su una pagina con il componente, lo script c'è già e serve solo scaricare e rivalutare gli intercept.
6. `run`. Esce (log in dev) se `qsiApi.API` non c'è; con `reload` chiama `API.unload()`; poi `API.load().done(API.run())` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L123-L139).
7. **Hook.** `isDataLoaded()` è protected e di default `of(true)` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L141-L149).
8. **Componente embedded.** `QualtricsEmbeddedFeedbackComponent` (`cx-qualtrics-embedded-feedback`) ha template vuoto e nessuna logica (feature-libs/qualtrics/components/qualtrics-embedded-feedback/qualtrics-embedded-feedback.component.ts:L9-L13): è solo un segnaposto nel DOM in cui un intercept Qualtrics "embedded" può renderizzarsi. Anche il suo stile è un placeholder (feature-libs/qualtrics/styles/_qualtrics-embedded-feedback.scss:L1-L4).

3.10 Installazione con gli schematics

`addTrackingFeatures`, `addSmartEditFeatures` e `addQualtricsFeatures` hanno la stessa sequenza: `validateSpartacusInstallation`, `analyzeCrossFeatureDependencies`, poi `chain([analyzeApplication, addFeatures, addPackageJsonDependenciesForLibrary(peerDependencies), finalizeInstallation])` (feature-libs/tracking/schematics/add-tracking/index.ts:L25-L43, feature-libs/smartedit/schematics/add-smartedit/index.ts:L25-L43, feature-libs/qualtrics/schematics/add-qualtrics/index.ts:L25-L43). I nomi delle feature selezionabili sono `Personalization`, `TMS-GTM`, `TMS-AEPL`, `SmartEdit`, `Qualtrics` (core-libs/schematics/src/shared/libs-constants.ts:L352-L364).

- **Personalization**: feature module `PersonalizationModule`, root `PersonalizationRootModule`, chunk lazy con `PERSONALIZATION_FEATURE`, dipendenza da User Profile (core-libs/schematics/src/shared/lib-configs/tracking-schematics-config.ts:L29-L50).
- **GTM / AEP**: root module `BaseTmsModule.forRoot()` e una `customConfig` che genera `<TmsConfig>{ tagManager: { gtm|aep: { events: [] } } }` forzando `lazy: false` (core-libs/schematics/src/shared/lib-configs/tracking-schematics-config.ts:L57-L103, core-libs/schematics/src/shared/lib-configs/tracking-schematics-config.ts:L107-L154); anche queste dichiarano la dipendenza da User Profile (core-libs/schematics/src/shared/lib-configs/tracking-schematics-config.ts:L75-L75, core-libs/schematics/src/shared/lib-configs/tracking-schematics-config.ts:L125-L125).
- **SmartEdit**: genera `<SmartEditConfig>` con `storefrontPreviewRoute`/`allowOrigin` presi dalle opzioni o dai placeholder `STOREFRONT_PREVIEW_ROUTE_PLACEHOLDER`/`ALLOWED_ORIGIN_PLACEHOLDER` (core-libs/schematics/src/shared/lib-configs/smartedit-schematics-config.ts:L54-L75) e aggiunge l'asset `smartedit/assets` (`glob: '**/*'`) ad `angular.json` (core-libs/schematics/src/shared/lib-configs/smartedit-schematics-config.ts:L48-L51).
- **Qualtrics**: crea `qualtrics-embedded-feedback.scss` con gli import delle funzioni/variabili/mixin bootstrap (core-libs/schematics/src/shared/lib-configs/qualtrics-schematics-config.ts:L45-L53).

Gli schematics in generale sono in 43 — Schematics e migrazioni.

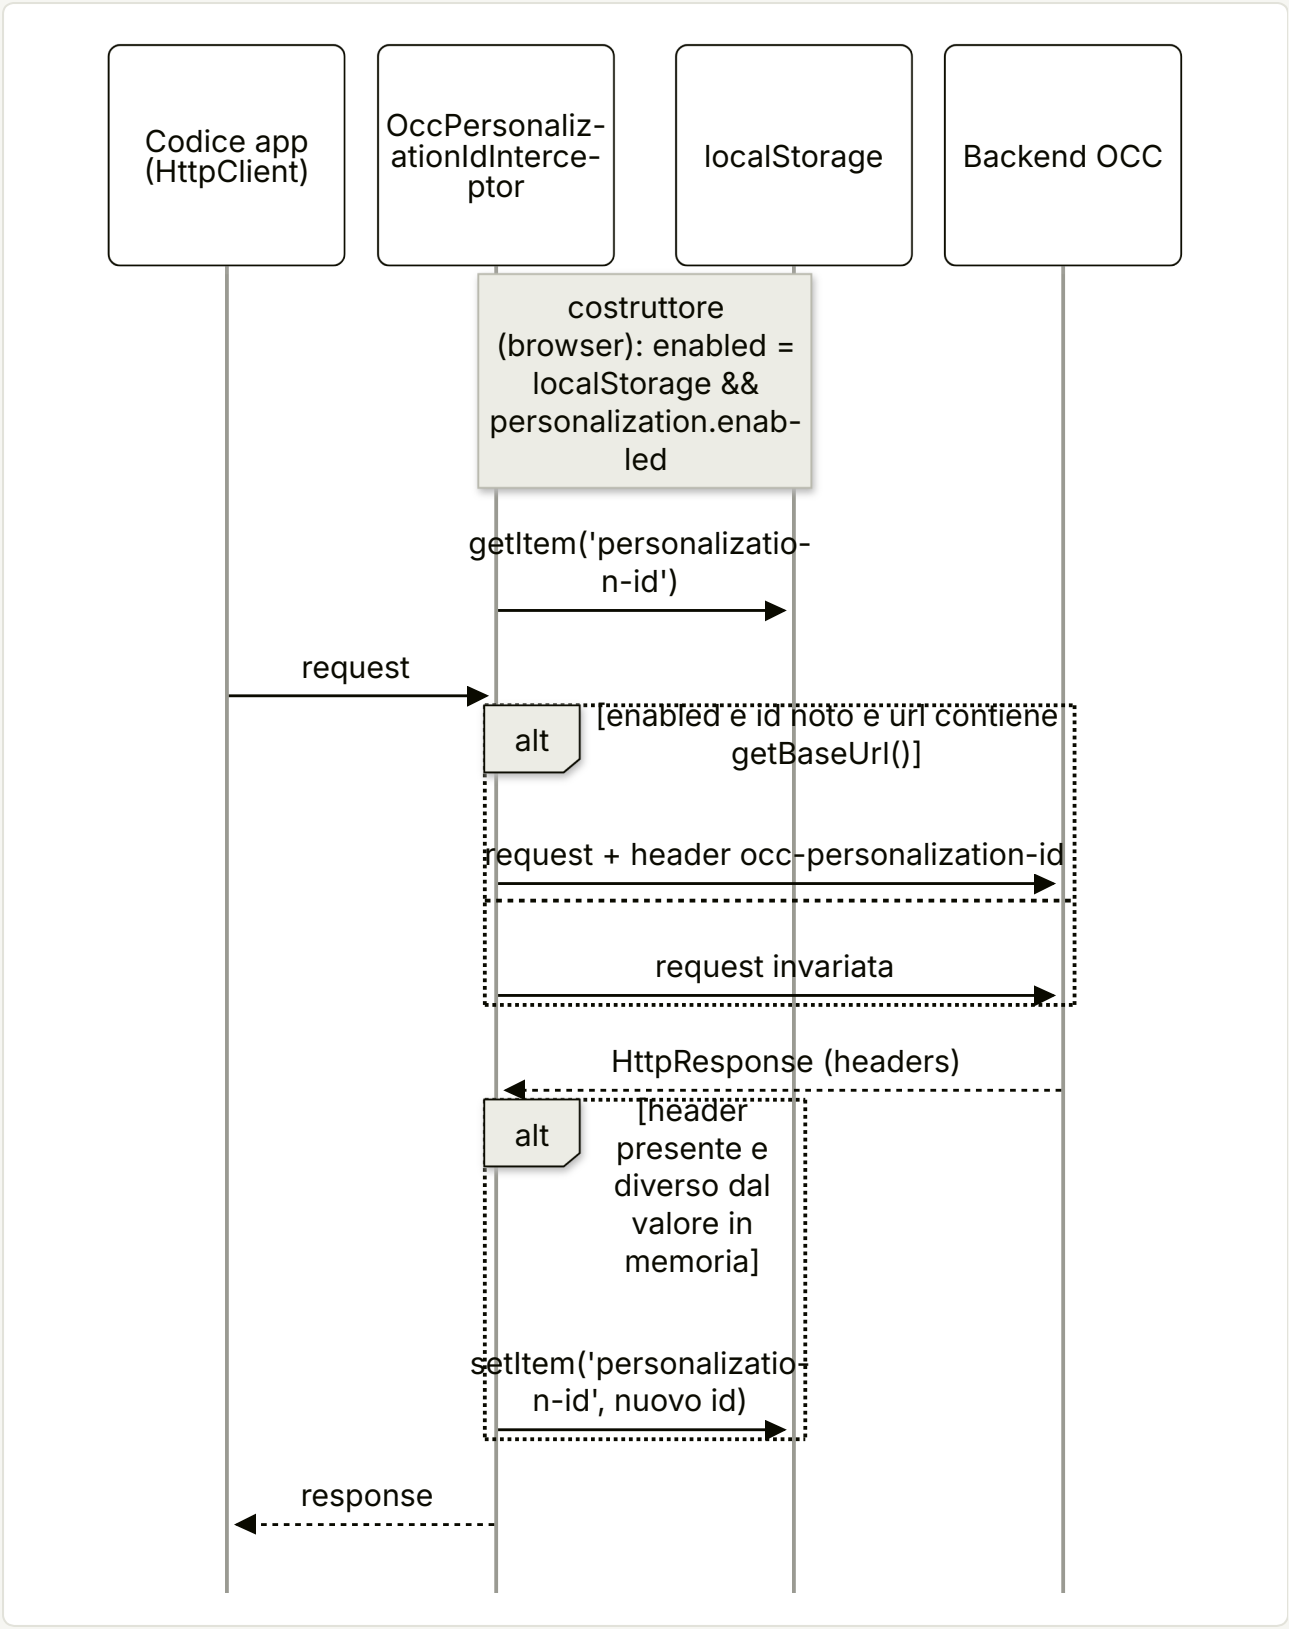
4. Diagrammi

4.1 TMS: bootstrap e flusso di un evento

■ **TAVOLA 33.1** diagramma a tutta pagina, in fondo al capitolo

Riferimenti: initializer `feature-libs/tracking/tms/core/base-tms.module.ts:L13-L29`; guardia SSR `feature-libs/tracking/tms/core/services/tms.service.ts:L46-L49`; loop e `init` `feature-libs/tracking/tms/core/services/tms.service.ts:L51-L75`; push `feature-libs/tracking/tms/core/services/tms.service.ts:L77-L94`; GTM `feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L25-L62`.

4.2 Personalization: ciclo dell'header id



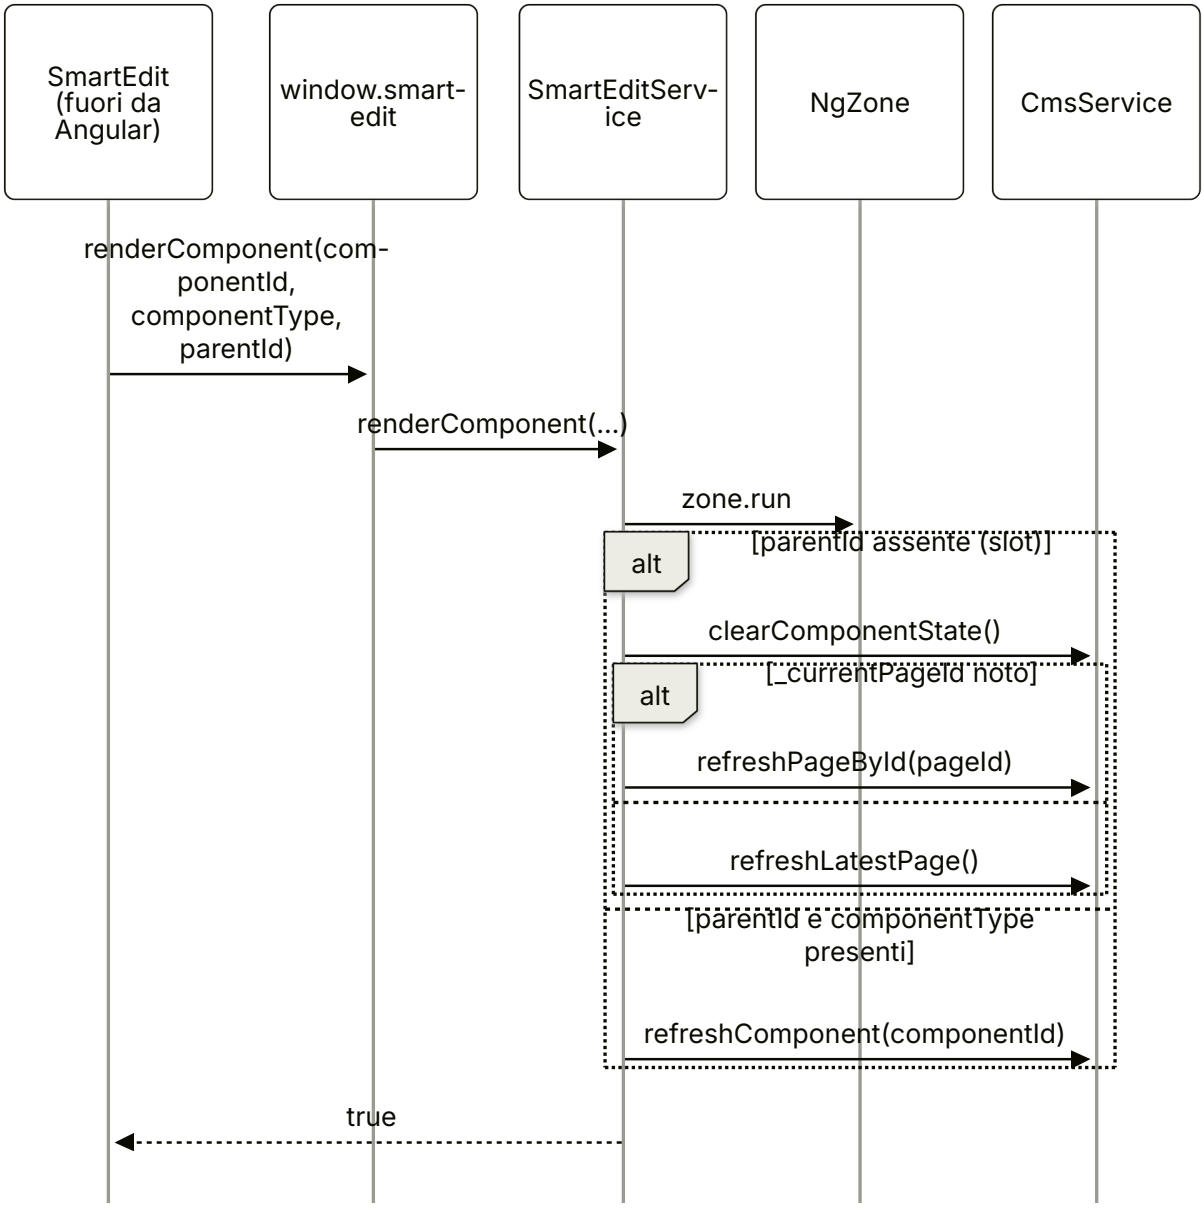
Riferimenti: `feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L34-L49` (costruttore), `feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L66-L76` (richiesta), `feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L78-L97` (risposta).

4.3 SmartEdit: avvio, lazy load e decorazione

■ **TAVOLA 33.2** diagramma a tutta pagina, in fondo al capitolo

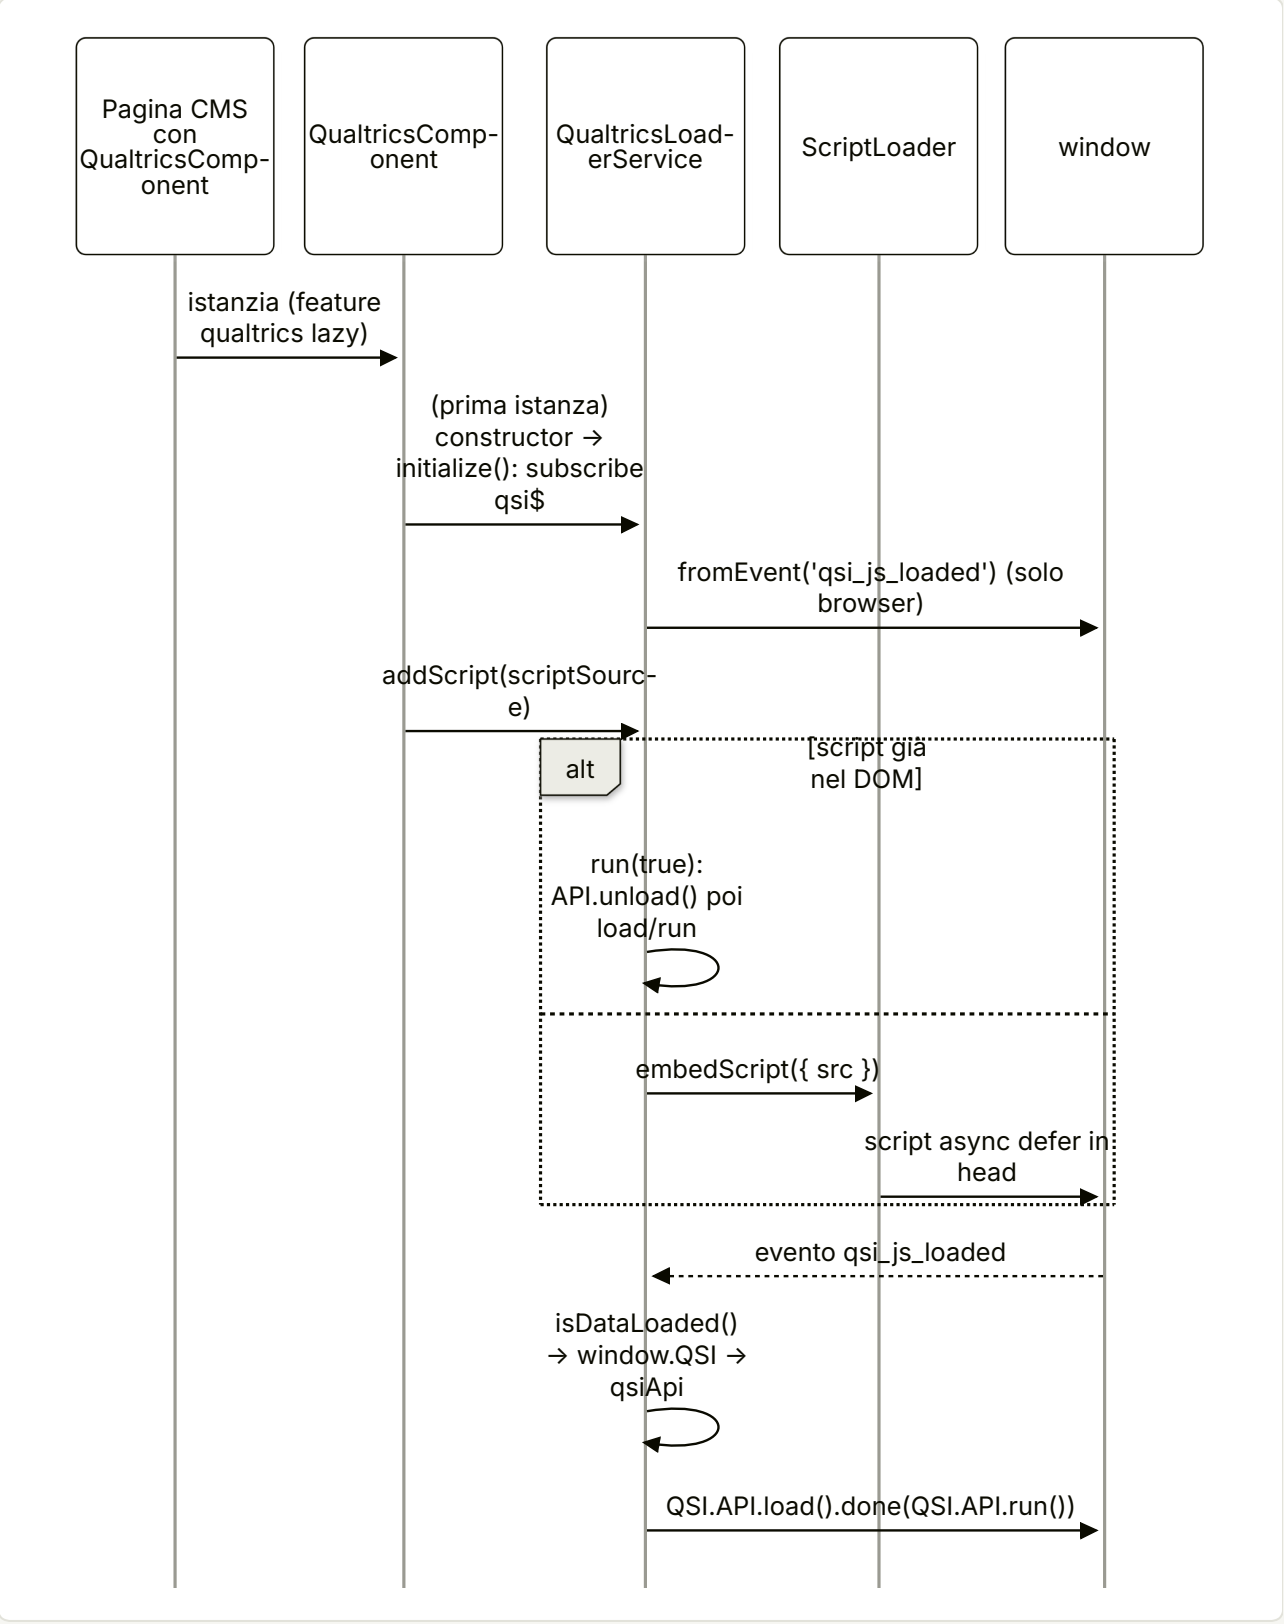
Riferimenti: feature-libs/smartedit/root/smart-edit-root.module.ts:L13-L34; feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L43-L96; feature-libs/smartedit/core/smart-edit-core.module.ts:L11-L18; core-libs/core/src/cms/services/dynamic-attribute.service.ts:L24-L64; feature-libs/smartedit/core/services/smart-edit.service.ts:L55-L191; feature-libs/smartedit/root/http-interceptors/cms-ticket.interceptor.ts:L25-L72.

4.4 SmartEdit: re-render dopo un edit



Riferimenti: feature-libs/smartedit/core/services/smart-edit.service.ts:L38-L52, feature-libs/smartedit/core/services/smart-edit.service.ts:L126-L149, core-libs/core/src/cms/facade/cms.service.ts:L197-L223, core-libs/core/src/cms/facade/cms.service.ts:L302-L309.

4.5 Qualtrics: script e API QSI



Riferimenti: `feature-libs/qualtrics/components/qualtrics-loader/qualtrics.component.ts:L22-L33`, `feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L55-L139`, `core-libs/core/src/util/script-loader.service.ts:L55-L93`.

5. Estratti di codice reale

5.1 `BaseTmsModule` e `tmsFactory`

TS

```ts
// feature-libs/tracking/tms/core/base-tms.module.ts:L10-L33
/**
 * The factory that conditionally (based on the configuration) starts collecting events
 */
export function tmsFactory(service: TmsService): () => void {
  const result = () => service.collect();
  return result;
}

@NgModule({})
export class BaseTmsModule {
  static forRoot(): ModuleWithProviders<BaseTmsModule> {
    return {
      ngModule: BaseTmsModule,
      providers: [
        {
          provide: APP_INITIALIZER,
          useFactory: tmsFactory,
          deps: [TmsService],
          multi: true,
        },
      ],
    };
  }
}
```

5.2 `TmsConfig` e i tipi di configurazione

TS

```ts
// feature-libs/tracking/tms/core/config/tms-config.ts:L14-L51
export interface TmsCollectorConfig {
  /** Should be enabled in development mode only */
  debug?: boolean;
  /**
   * The name for the data layer object.
   */
  dataLayerProperty?: string;
  /**
   * Events to send to the configured TMS.
   */
  events?: AbstractType<CxEvent>[];
  /**
   * The collector service implementation.
```

```
   */
  collector?: Type<TmsCollector>;
}

export interface TmsCollectors {
  [tms: string]: TmsCollectorConfig | undefined;
}

/**
 * TMS configuration
 */
@Injectable({
  providedIn: 'root',
  useExisting: Config,
})
export abstract class TmsConfig {
  /**
   * Tag manager config
   */
  tagManager?: TmsCollectors;
}

declare module '@spartacus/core' {
  interface Config extends TmsConfig {}
}
```

5.3 Il contratto `TmsCollector`

TS

```
// feature-libs/tracking/tms/core/model/tms.model.ts:L14-L40
export interface WindowObject extends Window {
  [prop: string]: any;
}

/**
 * Interface that a class can implement in order to be recognized as a TMS collector.
 */
export interface TmsCollector {
  /**
   * Initializes the data layer.
   */
  init(config: TmsCollectorConfig, windowObject: WindowObject): void;

  /**
   * Pushes the provided event to the data layer.
   */
  pushEvent<T extends CxEvent>(
    config: TmsCollectorConfig,
    windowObject: WindowObject,
```

```
    event: T | any
  ): void;

  /**
   * Maps the Spartacus event to another object.
   */
  map?<T extends CxEvent>(event: T): T | object;
}
```

5.4 `TmsService.collect()` (cuore del TMS)

TS

```
// feature-libs/tracking/tms/core/services/tms.service.ts:L46-L108
  collect(): void {
    if (!this.windowRef.isBrowser()) {
      return;
    }

    for (const tmsCollectorConfig in this.tmsConfig.tagManager) {
      if (!this.tmsConfig.tagManager?.hasOwnProperty(tmsCollectorConfig)) {
        continue;
      }

      const collectorConfig =
        this.tmsConfig.tagManager[tmsCollectorConfig] ?? {};

      if (!collectorConfig.collector) {
        if (isDevMode()) {
          this.logger.warn(
            `Skipping the '${tmsCollectorConfig}', as the collector is not defined.`
          );
        }
        continue;
      }

      const events =
        collectorConfig.events?.map((event) => this.eventsService.get(event)) ||
        [];
      const collector = this.injector.get<TmsCollector>(
        collectorConfig.collector
      );
      // eslint-disable-next-line @typescript-eslint/no-non-null-assertion
      collector.init(collectorConfig, this.windowRef.nativeWindow!);

      this.subscription.add(
        this.mapEvents(events).subscribe((event) => {
          if (collectorConfig.debug) {
            this.logger.log(
              `🎤 Pushing the following event to ${tmsCollectorConfig}: `,
```

```
            event
          );
        }

        event = collector.map?.(event) ?? event;
        collector.pushEvent(
          collectorConfig,
          // eslint-disable-next-line @typescript-eslint/no-non-null-assertion
          this.windowRef.nativeWindow!,
          event
        );
      })
    );
  }
}
// ...
protected mapEvents<T extends CxEvent>(
  events: Observable<T>[]
): Observable<T> {
  return merge(...events);
}
```

5.5 GtmCollectorService

TS

```
// feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L25-L62
  init(config: GtmCollectorConfig, windowObject: WindowObject): void {
    const dataLayerProperty = config.dataLayerProperty ?? 'dataLayer';
    windowObject[dataLayerProperty] = windowObject[dataLayerProperty] ?? [];

    if (config.gtmId) {
      (function (
        w: WindowObject,
        d: Document,
        s: string,
        l: string,
        i: string
      ) {
        w[l] = w[l] || [];
        w[l].push({ 'gtm.start': new Date().getTime(), event: 'gtm.js' });
        const f = d.getElementsByTagName(s)[0];
        const j = d.createElement(s) as HTMLScriptElement;
        const dl = l !== 'dataLayer' ? '&l=' + l : '';
        j.async = true;
        j.src = 'https://www.googletagmanager.com/gtm.js?id=' + i + dl;
        f.parentNode?.insertBefore(j, f);
      })(
        windowObject,
        this.winRef.document,
```

```
        'script',
        dataLayerProperty,
        config.gtmId
      );
    }
  }

  pushEvent<T extends CxEvent>(
    config: TmsCollectorConfig,
    windowObject: WindowObject,
    event: T | any
  ): void {
    const dataLayerProperty = config.dataLayerProperty ?? 'dataLayer';
    windowObject[dataLayerProperty].push(event);
  }
```

5.6 AepCollectorService

TS

```
// feature-libs/tracking/tms/aep/services/aep-collector.service.ts:L25-L44
  init(config: AepCollectorConfig, windowObject: WindowObject): void {
    const dataLayerProperty = config.dataLayerProperty ?? 'digitalData';
    windowObject[dataLayerProperty] = windowObject[dataLayerProperty] ?? {};

    if (config.scriptUrl) {
      this.scriptLoader.embedScript({ src: config.scriptUrl });
    }
  }

  pushEvent<T extends CxEvent>(
    config: TmsCollectorConfig,
    windowObject: WindowObject,
    event: T | any
  ): void {
    const dataLayerProperty = config.dataLayerProperty ?? 'digitalData';
    windowObject[dataLayerProperty] = {
      ...windowObject[dataLayerProperty],
      ...event,
    };
  }
```

5.7 Configurazione TMS della demo

TS

```
// projects/storefrontapp/src/app/spartacus/features/tracking/personalization-feature.module.ts:L22-L51
@NgModule({
  imports: [
    BaseTmsModule.forRoot(),
```

```
    GtmModule,
    AepModule,
    PersonalizationRootModule,
  ],
  providers: [
    provideConfig(<TmsConfig>{
      tagManager: {
        gtm: {
          events: [NavigationEvent, CartAddEntrySuccessEvent],
        },
        aep: {
          events: [NavigationEvent, CartRemoveEntrySuccessEvent],
        },
      },
    }),
    provideConfig(<CmsConfig>{
      featureModules: {
        [PERSONALIZATION_FEATURE]: {
          module: () =>
            import('@spartacus/tracking/personalization').then(
              (m) => m.PersonalizationModule
            ),
        },
      },
    }),
  ],
})
```

5.8 OccPersonalizationIdInterceptor

TS

```
// feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-
id.interceptor.ts:L29-L98
  constructor(
    private config: PersonalizationConfig,

7. Commenti e note notevoli dal sorgente

- `/** Should be enabled in development mode only */` sul flag `debug` del collector (feature-libs/tracking/tms/core/config/tms-config.ts:L15-L16): il log con emoji 🎤 stampa l'oggetto evento completo a ogni push.
- `/** Called only once to start collecting and dispatching events */` (feature-libs/tracking/tms/core/services/tms.service.ts:L43-L46): non c'è protezione contro chiamate ripetute; è l'`APP_INITIALIZER` a garantire che avvenga una volta.
- Il JSDoc di `mapEvents` documenta un parametro `@param collector` che la firma non ha più (feature-libs/tracking/tms/core/services/tms.service.ts:L98-L106): segno che in passato il mapping era per-collector; oggi è un semplice `merge` e il mapping per-collector si fa con `TmsCollector.map`.
- `// TODO: Inline this factory when we start releasing Ivy compiled libraries` (feature-libs/tracking/personalization/root/personalization-root.module.ts:L17-L17, identico in feature-libs/qualtrics/root/qualtrics-root.module.ts:L11-L11): residuo dell'era View Engine, quando le factory dovevano essere funzioni esportate per l'AOT.
- `// CHECK SONAR` a fine file (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-time.interceptor.ts:L101-L101), probabilmente legato alla duplicazione quasi totale con l'interceptor Id.
- `* Public API Surface of personalizatiion` (refuso) (feature-libs/tracking/personalization/public_api.ts:L8-L8).
- `// before adding contract to page, we need redirect to that page` (feature-libs/smartedit/core/services/smart-edit.service.ts:L71-L71) e `// only the first page is the smartedit preview page` (feature-libs/smartedit/core/services/smart-edit.service.ts:L100-L100).
- `// Clear all cached component data to ensure child components are also refreshed` (feature-libs/smartedit/core/services/smart-edit.service.ts:L135-L135): spiega perché un edit su uno slot svuota l'intera cache componenti invece dei soli figli.
- `// TODO: reprocess page API` (feature-libs/smartedit/core/services/smart-edit.service.ts:L152-L152).
- I commenti sul `sessionStorage` per i redirect full-page (CDC OIDC) e sul `SecurityError` in SSR (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L78-L79, feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L92-L93, feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L99-L99).
- `// Starts the intercept code evaluation right after loading the Site Intercept code for any defined intercepts or creatives` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L136-L138): l'intento è chiaro, l'implementazione però passa il *risultato* di `run()` a `done` (vedi trappola T-Q2).
- Nessun `@deprecated`/`FIXME` nei file del capitolo; il token `APP_INITIALIZER` usato da `BaseTmsModule` e `SmartEditRootModule` è però deprecato in Angular (angular:packages/core/src/application/application_init.ts:L38-L38).

8. Extension point

`QualtricsLoaderService.isDataLoaded()`	hook protected (default `of(true)`)	feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L147-L149	feature-libs/qualtrics/components/qualtrics-loader/index.ts:L8-L8
Mapping CMS `QualtricsComponent` / `QualtricsEmbeddedFeedbackComponent`	`cmsComponents` sovrascrivibili	feature-libs/qualtrics/components/qualtrics-components.module.ts:L21-L30	feature-libs/qualtrics/components/public_api.ts:L7-L8
`PERSONALIZATION_FEATURE`, `SMART_EDIT_FEATURE`, `QUALTRICS_FEATURE`	costanti per `featureModules`	feature-libs/tracking/personalization/root/feature-name.ts:L7-L7, feature-libs/smartedit/root/feature-name.ts:L7-L7, feature-libs/qualtrics/root/feature-name.ts:L7-L7	public_api dei rispettivi root

Nota: `GtmCollectorConfig` e `AepCollectorConfig` (con `gtmId`/`scriptUrl`) **non** sono esportate dai public API di `tms/gtm` e `tms/aep`, che esportano solo module e services (feature-libs/tracking/tms/gtm/public_api.ts:L7-L8); le chiavi sono comunque tipizzate grazie all'augmentation di `TmsCollectors` dichiarata nel file di default config (feature-libs/tracking/tms/gtm/config/default-gtm.config.ts:L14-L18).

8.1 Schema: un collector per un TMS custom

Esempio illustrativo (non presente nel repo), che usa solo simboli esportati da `@spartacus/tracking/tms/core` (`TmsCollector`, `TmsCollectorConfig`, `WindowObject`, `TmsConfig`) e dall'event bus di core:

```ts
// esempio — non nel repo
@Injectable({ providedIn: 'root' }) // oppure fornito nei providers di un modulo eager: TmsService lo risolve dall'injector root (T3)
export class MyTmsCollector implements TmsCollector {
  init(config: TmsCollectorConfig, w: WindowObject): void {
    const name = config.dataLayerProperty ?? 'myLayer';
    w[name] = w[name] ?? [];
  }
```

```
  map<T extends CxEvent>(event: T): object {
    return { name: (event.constructor as any).type, payload: event };
  }
  pushEvent<T extends CxEvent>(config: TmsCollectorConfig, w: WindowObject, event: T | any): void {
    w[config.dataLayerProperty ?? 'myLayer'].push(event);
  }
}

// nel modulo dell'app, insieme a BaseTmsModule.forRoot()
provideConfig(<TmsConfig>{
  tagManager: { myTms: { collector: MyTmsCollector, events: [NavigationEvent] } },
});
```

Il funzionamento poggia su feature-libs/tracking/tms/core/services/tms.service.ts:L51-L94 (qualsiasi chiave di `tagManager` con un `collector` viene considerata). Per sostituire solo la trasformazione degli eventi di GTM basta estendere `GtmCollectorService` aggiungendo `map` e impostarla come `tagManager.gtm.collector`.

8.2 Schema: attendere dati applicativi prima di Qualtrics

TS

```
// esempio — non nel repo
@Injectable({ providedIn: 'root' })
export class MyQualtricsLoaderService extends QualtricsLoaderService {
  // inject() solo in un field initializer: isDataLoaded() gira dentro switchMap, fuori dall'injection context
  protected activeCart = inject(ActiveCartFacade);
  protected isDataLoaded(): Observable<boolean> {
    return this.activeCart.isStable(); // qualsiasi Observable<boolean>
  }
}
// providers: [{ provide: QualtricsLoaderService, useClass: MyQualtricsLoaderService }]
```

Hook documentato a feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L141-L149. Attenzione alla trappola T-Q1: se l'Observable emette `false`, il servizio finisce per memorizzare `EMPTY` come API.

8.3 Ricette correlate (Parte III)

- Override di config (`provideConfig`), sostituzione di servizi via DI (`useClass`), interceptor ed eventi custom: 50 — Ricette: configurazione, DI, interceptor, eventi.
- Sostituire il mapping CMS di `QualtricsComponent`/`QualtricsEmbeddedFeedbackComponent` o creare un componente CMS che faccia da contenitore: 51 — Ricette: componenti CMS, outlet, route e layout.
- Aggiungere/organizzare feature lazy (`featureModules`) come fanno Personalization, SmartEdit e Qualtrics: 53 — Ricette: feature, cart, checkout, stili, i18n.
- Estendere i servizi protetti (`SmartEditService`, `QualtricsLoaderService`, collector) in modo robusto agli upgrade: 54 — Upgrade-safe.

9. Trappole, casi limite, comportamenti controintuitivi

Tracking / TMS

- **T1 — Config letta una sola volta.** `collect()` legge `tagManager` una volta, nell'`APP_INITIALIZER`: collector o eventi aggiunti dopo (ad esempio config fornita da un modulo lazy) non vengono considerati (feature-libs/tracking/tms/core/base-tms.module.ts:L13-L16, feature-libs/tracking/tms/core/services/tms.service.ts:L46-L51).
- **T2 — Collector senza eventi.** Senza `events`, il collector viene comunque inizializzato (data layer creato, script GTM/AEP caricato) ma non riceve nulla; lo schematic genera proprio `events: []` (feature-libs/tracking/tms/core/services/tms.service.ts:L68-L75, core-libs/schematics/src/shared/lib-configs/tracking-schematics-config.ts:L89-L95).
- **T3 — Collector nell'injector root.** `this.injector.get(collector)` usa l'injector di `TmsService` (root): un collector non disponibile nel root injector (es. fornito solo in un modulo lazy) genera un errore di DI (feature-libs/tracking/tms/core/services/tms.service.ts:L71-L73).
- **T4 — AEP sovrascrive.** `pushEvent` di AEP fa un merge shallow sull'oggetto: proprietà omonime di eventi diversi si sovrascrivono e la storia non è conservata, a differenza dell'array GTM (feature-libs/tracking/tms/aep/services/aep-collector.service.ts:L39-L43 vs feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L60-L61). Inoltre, essendo un nuovo oggetto, chi conserva un riferimento al vecchio `digitalData` non vede gli aggiornamenti.
- **T5 — Data layer GTM non-array.** `pushEvent` assume che `window[dataLayerProperty]` sia un array (creato in `init`); se un altro script lo sostituisce con un non-array, `push` fallisce (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L27-L27, feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L61-L61).
- **T6 — Nessun `<script>` nel documento.** Lo snippet GTM inserisce lo script prima di `getElementsByTagName('script')[0]`; se non esiste nessun `<script>`, `f` è undefined e `f.parentNode` lancia — l'optional chaining è solo su `parentNode` (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L39-L44). In un'app Angular buildata gli script del bundle ci sono, quindi è un caso essenzialmente teorico (test o ambienti particolari).
- **T7 — Demo senza vendor.** Nella demo GTM/AEP sono configurati senza `gtmId`/`scriptUrl`: i data layer si popolano ma nessuno script vendor è caricato (projects/storefrontapp/src/app/spartacus/features/tracking/personalization-feature.module.ts:L30-L39). È utile per ispezionare `window.dataLayer` in console, non per vedere dati in GTM.
- **T8 — Eventi interi nel data layer.** Senza `map`, nel data layer finisce l'istanza `CxEvent` così com'è (es. `NavigationEvent` con `context`, `semanticRoute`, `url`: core-libs/storefront/events/navigation/navigation.event.ts:L13-L29). Un evento carrello può contenere dati che non si vogliono inviare a un TMS: valutare un `map` che selezioni i campi (feature-libs/tracking/tms/core/services/tms.service.ts:L86-L86).

Personalization

- **T9 — Niente header in SSR.** `enabled` resta `false` fuori dal browser, quindi le richieste OCC lato server non portano gli header di personalizzazione (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L24-L24, feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L34-L37). La pagina renderizzata dal server è quindi non personalizzata.
- **T10 — `httpHeaderName` parziale.** `httpHeaderName?.id.toLowerCase()` ha l'optional chaining solo fino a `httpHeaderName?.`: se `httpHeaderName` c'è ma `id` manca, `TypeError` nel costruttore; il warning in dev copre

solo l'assenza di `httpHeaderName` (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L40-L46). Poiché `id` e `timestamp` sono tipizzati come obbligatori (feature-libs/tracking/personalization/root/config/personalization-config.ts:L17-L20), TypeScript protegge solo se la config è tipizzata.

- **T11 — Casing degli header.** Il controllo `event.headers.keys().includes(this.requestHeader)` confronta col nome minuscolo, mentre `HttpHeaders.keys()` restituisce i nomi nel casing originale (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L83-L83, angular:packages/common/http/src/headers.ts:L115-L119, angular:packages/common/http/src/headers.ts:L172-L176). Funziona perché XHR/fetch espongono gli header di risposta in minuscolo. DA VERIFICARE per backend/proxy e backend HTTP specifici (non verificabile nel repo).
- **T12 — Filtro URL per sottostringa.** `request.url.includes(occEndpoints.getBaseUrl())`: richieste non-OCC il cui URL contiene la base URL riceverebbero gli header (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L69-L69).
- **T13 — Payload malformato.** `buildPersonalizationContext` usa `JSON.parse(atob(...))` senza try/catch: un payload malformato genera un errore nello stream, che termina (feature-libs/tracking/personalization/core/services/personalization-context.service.ts:L57-L66).
- **T14 — Feature lazy senza mapping.** `PersonalizationModule`/`PersonalizationCoreModule` non mappano `PersonalizationScriptComponent` in `cmsComponents` (feature-libs/tracking/personalization/core/personalization-core.module.ts:L9-L10). Quando una pagina contiene quel componente, `CmsFeaturesService.getCmsMapping` risolve la feature e restituisce `componentsMappings?.[type]`, cioè undefined (core-libs/storefront/cms-structure/services/cms-features.service.ts:L89-L103); `CmsComponentsService` scarta gli undefined con `filter(isNotUndefined)` e unisce i resolver con `forkJoin` (core-libs/storefront/cms-structure/services/cms-components.service.ts:L109-L110, core-libs/storefront/cms-structure/services/cms-components.service.ts:L117-L141). In RxJS un `forkJoin` con una sorgente che completa senza emettere completa senza emettere (deps:rxjs-7.8.2/package/src/internal/observable/forkJoin.ts:L77-L80). `determineMappings` è sottoscritto da `ComponentWrapperDirective.ngOnInit` (che lancia il componente solo nella callback `next`) e da `CmsPageGuardService.canActivatePage` (core-libs/storefront/cms-structure/page/component/component-wrapper.directive.ts:L67-L79, core-libs/storefront/cms-structure/guards/cms-page-guard.service.ts:L71-L75); le guard del router applicano `first()` al risultato (angular:packages/router/src/operators/check_guards.ts:L168-L168). DA VERIFICARE l'effetto concreto a runtime (componente semplicemente non renderizzato, warning "No component implementation found" da core-libs/storefront/cms-structure/services/cms-components.service.ts:L165-L181, o impatto sulla guard di pagina): richiede una pagina CMS reale con `PersonalizationScriptComponent` e non è osservabile senza backend.
- **T15 — Contesto iniziale vuoto per CDS.** CDS parte da `{ segments: undefined, actions: undefined }` e usa `withLatestFrom`: i push event emessi prima che la pagina corrente contenga il componente script portano segmenti/azioni undefined (integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L98-L112).

SmartEdit

- **T16 — `resolveFeature` senza error handler.** `load()` sottoscrive `resolveFeature('smartEdit')` senza gestione errori: se l'app non configura `featureModules.smartEdit.module`, l'errore "No module defined for Feature Module smartEdit" non è gestito (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L45-L45, core-libs/core/src/lazy-loading/feature-modules.service.ts:L47-L52).
- **T17 — Ticket "appiccicoso".** Il ticket salvato in `sessionStorage` non viene mai rimosso nel codice: per tutta la vita del tab, ogni reload è considerato "in SmartEdit" (fallback), con script injector caricato e `cmsTicketId` aggiunto alle chiamate (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L91-L96, feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L109-

L118). In sviluppo, aprire lo storefront nello stesso tab dopo averlo usato in SmartEdit dà comportamenti inattesi: chiudere il tab o cancellare la chiave.

- **T18 — Parsing semplificato.** `isInitialSmartEditPage` confronta solo l'ultimo segmento del path con `storefrontPreviewRoute`, e il valore di `cmsTicketId` non è URL-decoded (`split('=')[1]`) (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L66-L66, feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L80-L83).
- **T19 — Path dell'injector hardcoded.** Lo `src` è sempre il path relativo hardcoded `assets/webApplicationInjector.js`: l'app deve copiare l'asset — lo fa lo schematic in `angular.json` (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L47-L48, core-libs/schematics/src/shared/lib-configs/smartedit-schematics-config.ts:L48-L51).
- **T20 — SSR.** In SSR `isLaunchedInSmartEdit` può essere vero solo per la pagina iniziale (il fallback da `sessionStorage` è saltato): in quel caso `load()` risolve comunque la feature e chiama `embedScript`, che senza callback non è bloccato in SSR e non controlla i duplicati lato server (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L43-L55, core-libs/core/src/util/script-loader.service.ts:L55-L63).
- **T21 — `id` come proprietà.** `id: 'text/smartedit-injector'` non inizia con `data-`, quindi `ScriptLoader` lo assegna come proprietà `script.id` (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L50-L53, core-libs/core/src/util/script-loader.service.ts:L73-L80).
- **T22 — Decisione per sottostringa.** `CmsTicketInterceptor` decide su `/cms/`, `/products/`, `/productList` nell'URL, non sugli endpoint configurati: endpoint OCC personalizzati con path diversi non ricevono il ticket (feature-libs/smartedit/root/http-interceptors/cms-ticket.interceptor.ts:L33-L42).
- **T23 — Classi del `<body>` cancellate.** `addPageContract` rimuove tutte le classi del `<body>`, comprese quelle aggiunte dall'app o da altre librerie (feature-libs/smartedit/core/services/smart-edit.service.ts:L85-L90). Accade a ogni cambio pagina, ma solo in SmartEdit.
- **T24 — `reprocessPage` non legato.** `window.smartedit.reprocessPage = this.reprocessPage` assegna il metodo senza `bind` ed è comunque un no-op (feature-libs/smartedit/core/services/smart-edit.service.ts:L51-L51, feature-libs/smartedit/core/services/smart-edit.service.ts:L151-L153). Chi lo sovrascrive in una sottoclasse non può usare `this`.
- **T25 — `renderComponent` silenzioso.** Con `parentId` ma senza `componentType` non accade nulla, e il metodo restituisce sempre `true` (feature-libs/smartedit/core/services/smart-edit.service.ts:L131-L148).
- **T26 — Subscription annidata.** `processCmsPage` contiene una subscribe annidata senza unsubscribe su `getCurrentPage()` che vive quanto l'app (feature-libs/smartedit/core/services/smart-edit.service.ts:L66-L74).
- **T27 — Preview solo con codici del BaseSite.** `goToPreviewPage` naviga solo per la prima pagina e solo se il BaseSite definisce i codici di preview; la route `product` riceve `name: ''` (feature-libs/smartedit/core/services/smart-edit.service.ts:L101-L119).

Qualtrics

- **T-Q1 — `EMPTY` scambiato per l'API.** Se `isDataLoaded()` emette `false`, `map` restituisce `EMPTY` (un Observable, quindi truthy), che supera `filter(Boolean)` e diventa `qsiApi`; `run()` trova `qsiApi.API` undefined e logga "The QSI api is not available" (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L68-L70, feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L124-L129). Un successivo `addScript` → `run(true)` userebbe lo stesso `qsiApi` errato finché non arriva un nuovo `qsi_js_loaded` con dati pronti.
- **T-Q2 — `done(run())`.** `this.qsiApi.API.load().done(this.qsiApi.API.run())` invoca `run()` immediatamente e passa il suo valore di ritorno a `done`, invece di una callback (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L138-L138): `run` parte prima che `load` abbia finito.

- **T-Q3 — Script anche in SSR.** `QualtricsComponent` agisce nel costruttore: anche in SSR chiama `addScript` → `embedScript`, e lo script Qualtrics finisce nell'HTML generato dal server (feature-libs/qualtrics/components/qualtrics-loader/qualtrics.component.ts:L22-L28, core-libs/core/src/util/script-loader.service.ts:L55-L63). Nel browser, durante l'idratazione, `hasScript` trova lo script già presente e `addScript` passa al ramo `run(true)` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L91-L94).
- **T-Q4 — Componente embedded senza feature.** `QualtricsEmbeddedFeedbackComponent` non è nella lista `cmsComponents` della feature `qualtrics` (feature-libs/qualtrics/root/qualtrics-root.module.ts:L14-L18) pur essendo mappato in `QualtricsComponentsModule` (feature-libs/qualtrics/components/qualtrics-components.module.ts:L21-L30). Poiché `CmsFeaturesService` associa a una feature solo i componenti elencati in `cmsComponents` (core-libs/storefront/cms-structure/services/cms-features.service.ts:L65-L72), una pagina che contenga solo il componente embedded non provoca il caricamento lazy. DA VERIFICARE: se un'altra parte dell'app (o una pagina precedente con `QualtricsComponent`) ha già caricato la feature, il mapping potrebbe essere comunque disponibile tramite la config fusa; dipende dall'ordine di navigazione.
- **T-Q5 — Evento perso.** Il listener `qsi_js_loaded` è registrato solo alla prima istanziazione di `QualtricsLoaderService` (root): se l'evento è già scattato prima (script inserito da altri, es. in `index.html`), non viene intercettato, e serve un `addScript` che passi per `run(true)` — che però a sua volta esce perché `qsiApi` non è stato valorizzato (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L77-L83, feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L123-L129).

---

10. Come fare debug

TMS.

- Impostare `debug: true` sulla voce di `tagManager`: ogni push viene loggato con 🎤 `Pushing the following event to <tms>` (feature-libs/tracking/tms/core/services/tms.service.ts:L79-L84). Il logger è `LoggerService`, quindi segue eventuali override del logger (vedi 41 — Errori HTTP, error handling, logger).
- In console del browser: `window.dataLayer` (GTM) o `window.digitalData` (AEP), o il nome configurato in `dataLayerProperty`.
- Nessun evento? Controllare: (a) che `BaseTmsModule.forRoot()` sia importato (senza `forRoot` non c'è initializer: feature-libs/tracking/tms/core/base-tms.module.ts:L18-L19); (b) che la voce abbia un `collector` (altrimenti warning "Skipping the '...'", feature-libs/tracking/tms/core/services/tms.service.ts:L59-L66); (c) che la classe evento in `events` sia esattamente quella emessa — `EventService.get` è per tipo (core-libs/core/src/event/event.service.ts:L90-L96).
- Breakpoint utili: `TmsService.collect` e `GtmCollectorService.pushEvent`.

Personalization.

- DevTools → Application → Local Storage: chiavi `personalization-id` e `personalization-time`. DevTools → Network: header `occ-personalization-id`/`occ-personalization-time` sulle richieste OCC.
- Se le chiavi spariscono a ogni avvio, `personalization.enabled` è false (pulizia a feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L50-L54).
- Warning in dev "There is no httpHeaderName configured in Personalization" e "There is no context configured in Personalization." indicano config mancanti (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L40-L44, feature-libs/tracking/personalization/core/services/personalization-context.service.ts:L31-L35).

- Per il contesto: ispezionare nello store CMS la pagina corrente, slot `PlaceholderContentSlot`, componente `PersonalizationScriptComponent`, `properties.script.data`, e decodificarlo a mano con `JSON.parse(atob(...))`.

SmartEdit.

- Simulare SmartEdit fuori dall'editor aprendo `/<...>/cx-preview?cmsTicketId=<qualsiasi>`: il launcher persiste il ticket e carica la feature (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L80-L87). Verificare in Network che il chunk `@spartacus/smartedit` e lo script `webApplicationInjector.js` (cartella `assets`) vengano scaricati, e che le chiamate `/cms/` portino `cmsTicketId`.
- DevTools → Application → Session Storage: chiave `smartedit.cmsTicketId`. Cancellarla per "uscire" da SmartEdit (T17).
- Ispezionare il DOM: slot e componenti dovrebbero avere attributi `data-smartedit-*` e classi dal contratto (feature-libs/smartedit/core/services/smart-edit.service.ts:L158-L191); se mancano, `properties` dal backend è vuoto (senza ticket valido il backend non le fornisce — DA VERIFICARE lato backend).
- In console: `window.smartedit.renderComponent('<uid>', '<type>', '<parentUid>')` forza il refresh di un componente; senza terzo argomento ricarica la pagina (feature-libs/smartedit/core/services/smart-edit.service.ts:L126-L149).
- Errore "No module defined for Feature Module smartEdit" in console → manca `featureModules.smartEdit.module` (T16).

Qualtrics.

- Warning "We're unable to add the Qualtrics deployment code..." → manca `qualtrics.scriptSource` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics.component.ts:L28-L31).
- Log "The QSI api is not available" → `window.QSI.API` assente al momento di `run` (T-Q1, T-Q5).
- In console: `window.QSI`, e `dispatchEvent(new Event('qsi_js_loaded'))` per simulare l'evento di caricamento letto da `fromEvent` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L55-L58).
- Ricordare che la feature si carica solo se la pagina CMS contiene `QualtricsComponent` (feature-libs/qualtrics/root/qualtrics-root.module.ts:L11-L27).

Test. Le tre librerie hanno `vitest.config.ts` con ambiente `jsdom`, pool `forks` e coverage v8 con soglie 85% (statements/lines/functions) e 65% (branches) (feature-libs/tracking/vitest.config.ts:L21-L55): `nx test-vitest tracking`, `nx test-vitest smartedit`, `nx test-vitest qualtrics` (vedi 44 — Strategia di test e tooling).

---

11. Domande di autoverifica

1. **Perché importare `BaseTmsModule` senza `forRoot()` non attiva il tracking?** Perché `@NgModule({})` è vuoto: è `forRoot()` a registrare l'`APP_INITIALIZER` con `tmsFactory` che chiama `TmsService.collect()` (feature-libs/tracking/tms/core/base-tms.module.ts:L18-L33).
2. **Ho importato `GtmModule` e messo `gtmId`, ma `window.dataLayer` resta con il solo `gtm.js`. Perché?** Probabilmente manca `events`: il collector è inizializzato comunque (snippet GTM eseguito), ma senza eventi non riceve push (feature-libs/tracking/tms/core/services/tms.service.ts:L68-L75). `GtmModule` non definisce eventi di default (feature-libs/tracking/tms/gtm/config/default-gtm.config.ts:L20-L26).
3. **Qual è la differenza osservabile fra il data layer GTM e quello AEP dopo tre eventi?** GTM: array con tre elementi aggiunti con `push` (feature-libs/tracking/tms/gtm/services/gtm-collector.service.ts:L60-

L61). AEP: un solo oggetto, ricreato a ogni evento con merge shallow, in cui le proprietà omonime sono sovrascritte dall'ultimo evento (feature-libs/tracking/tms/aep/services/aep-collector.service.ts:L39-L43).

4. **Perché un collector custom deve essere disponibile nel root injector?** Perché `TmsService` (`providedIn: 'root'`) lo risolve con il proprio `Injector` (feature-libs/tracking/tms/core/services/tms.service.ts:L27-L41, feature-libs/tracking/tms/core/services/tms.service.ts:L71-L73).
5. **Le richieste OCC fatte durante l'SSR portano l'header** `occ-personalization-id`**?** No: l'interceptor si abilita solo nel browser (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L34-L37), quindi in SSR `enabled` resta `false` e la richiesta passa invariata (feature-libs/tracking/personalization/root/http-interceptors/occ-personalization-id.interceptor.ts:L62-L64).
6. **Da dove legge Spartacus segmenti e azioni di personalizzazione, e in che formato?** Dalla pagina CMS corrente, slot `PlaceholderContentSlot`, componente `PersonalizationScriptComponent`, `properties.script.data`: JSON in base64 con valori di actions e segments a loro volta in base64 (feature-libs/tracking/personalization/core/services/personalization-context.service.ts:L37-L69, default a feature-libs/tracking/personalization/root/config/default-personalization-config.ts:L16-L19).
7. **Come fa Spartacus a sapere di essere dentro SmartEdit dopo un redirect full-page che ha perso i parametri dell'URL?** Il ticket viene salvato in `sessionStorage` alla prima pagina (`cx-preview` + `cmsTicketId`) e, se l'URL non porta più il contesto, è ripristinato da lì; la sua presenza basta (feature-libs/smartedit/root/services/smart-edit-launcher.service.ts:L74-L96).
8. **Come arrivano i decoratori di** `SmartEditCoreModule`**, fornito in un modulo lazy, a** `DynamicAttributeService` **che è un servizio root?** Tramite `UnifiedInjector.getMulti`, che osserva il root injector più gli injector dei moduli lazy caricati e accumula le istanze multi (core-libs/core/src/lazy-loading/unified-injector.ts:L32-L35, core-libs/core/src/lazy-loading/unified-injector.ts:L79-L93, core-libs/core/src/cms/services/dynamic-attribute.service.ts:L24-L32).
9. **Una proprietà** `catalogVersionUuid` **nel gruppo** `smartedit` **di un componente: quale attributo HTML produce?** `data-smartedit-catalog-version-uuid`: prefisso `data-<gruppo>-` più nome spezzato sulle maiuscole, unito con `-` e messo in minuscolo (feature-libs/smartedit/core/services/smart-edit.service.ts:L166-L186).
10. **Perché** `renderComponent` **usa** `zone.run`**, e cosa fa se viene chiamato senza** `parentId`**?** Perché è invocato da SmartEdit tramite `window.smartedit`, fuori dalla zona Angular; senza `parentId` tratta l'oggetto come slot: `clearComponentState()` e ricarica della pagina per id o dell'ultima pagina (feature-libs/smartedit/core/services/smart-edit.service.ts:L126-L149).
11. **Cosa c'è di sbagliato in** `this.qsiApi.API.load().done(this.qsiApi.API.run())`**?** `run()` viene eseguito subito e a `done` viene passato il suo valore di ritorno, non una callback: la valutazione non attende il completamento di `load()` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L138-L138).
12. **Come si fa attendere a Qualtrics che certi dati applicativi siano pronti?** Estendendo `QualtricsLoaderService` e sovrascrivendo l'hook protected `isDataLoaded()` (default `of(true)`), che `qsi$` attraversa con `switchMap` prima di leggere `window.QSI` (feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L66-L71, feature-libs/qualtrics/components/qualtrics-loader/qualtrics-loader.service.ts:L141-L149).

TAVOLA 33.1 **4.1 TMS: bootstrap e flusso di un evento**

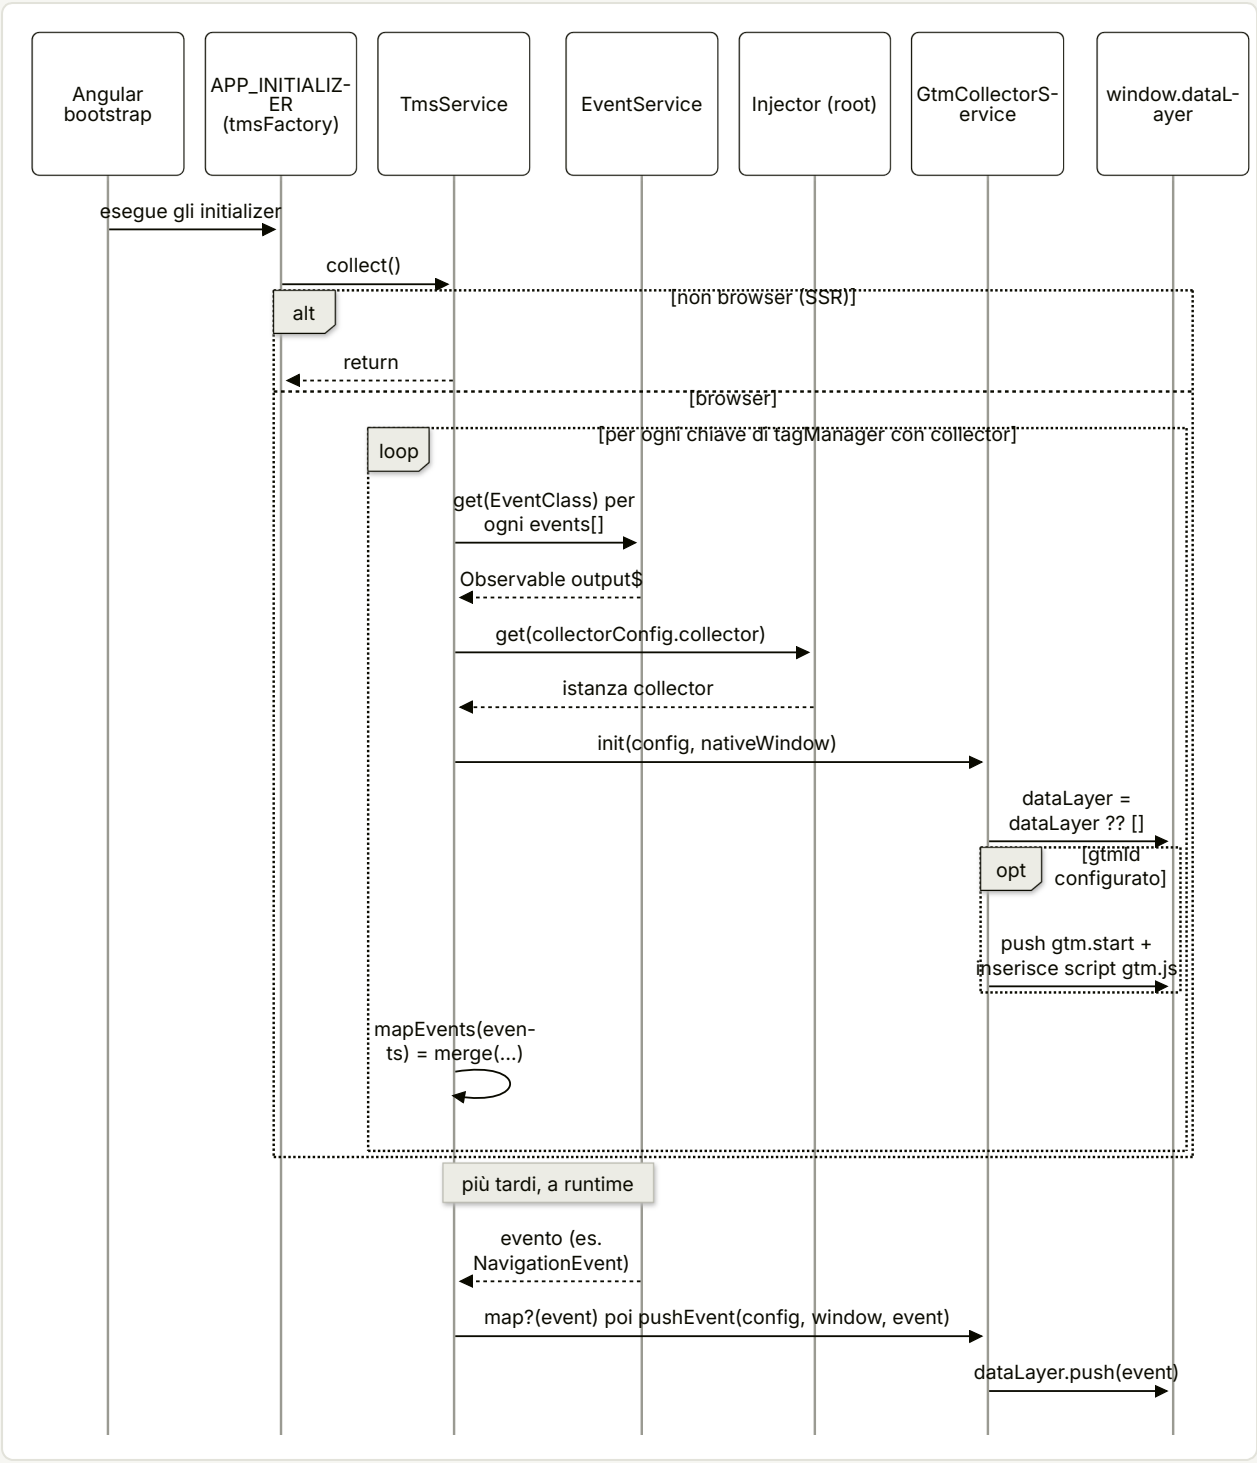

TAVOLA 33.2 **4.3 SmartEdit: avvio, lazy load e decorazione**

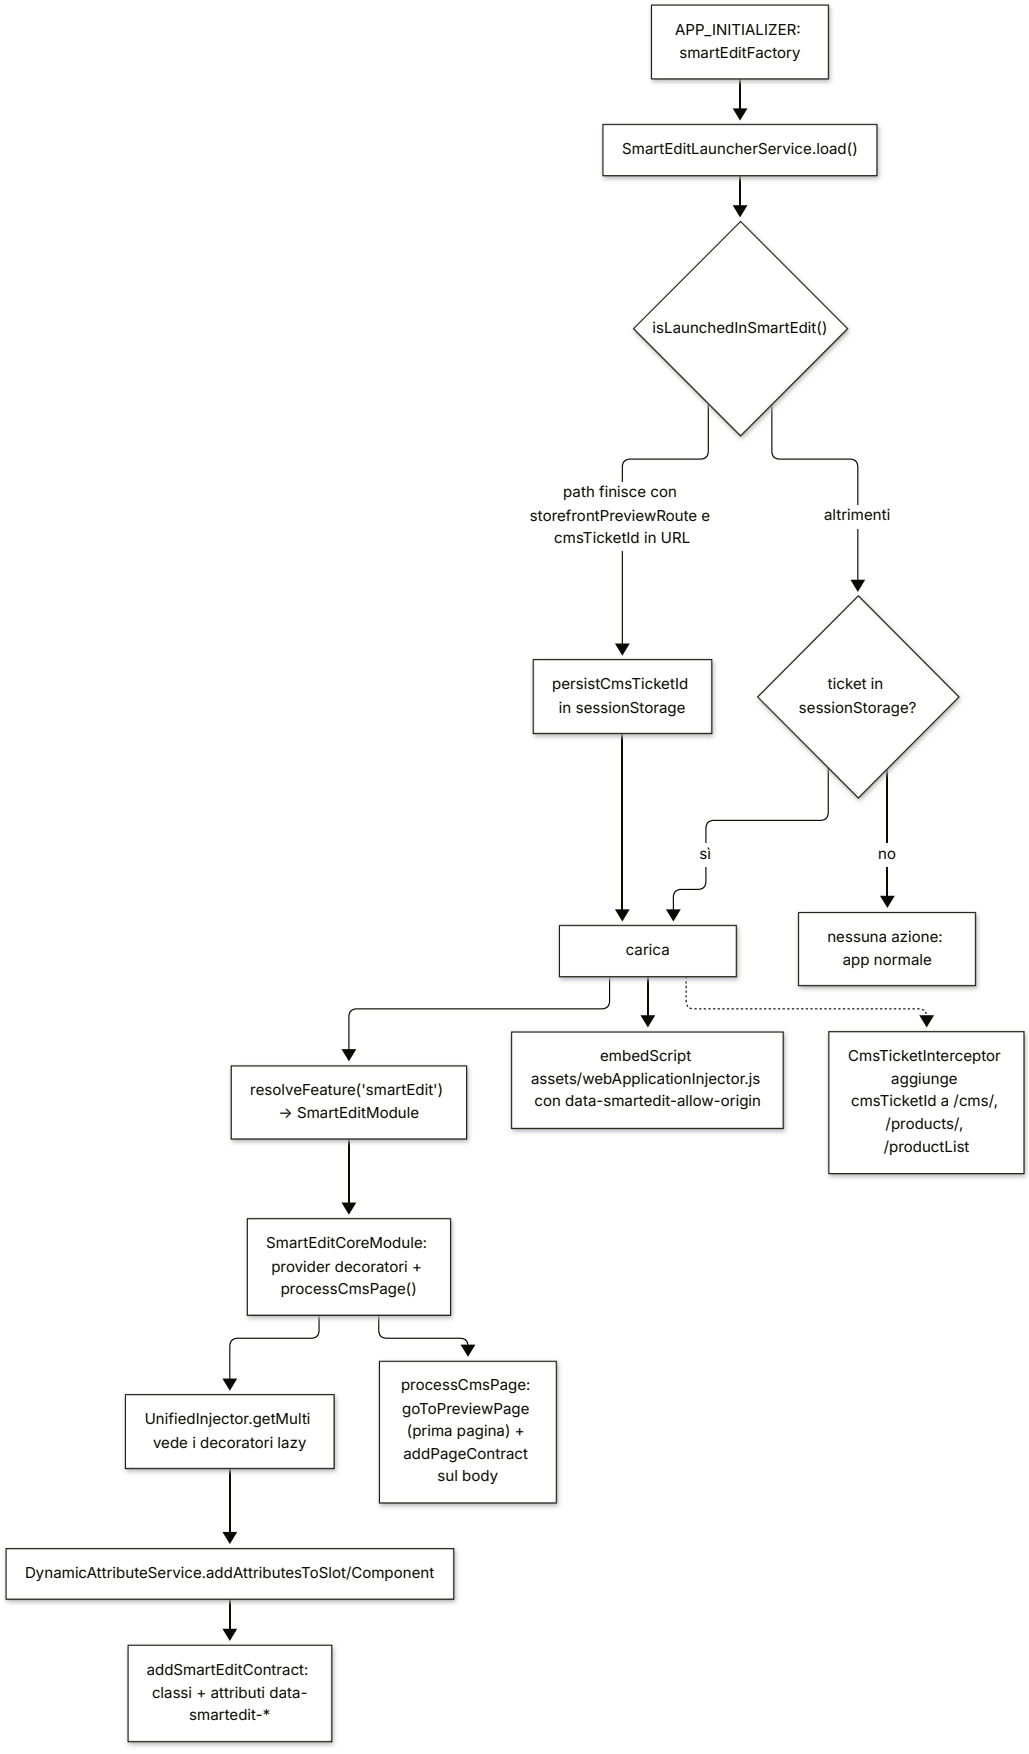

34

Integration libs: CDC, CDP, CDS, segment-refs

Integrazioni con Customer Data Cloud, CDP, Context-Driven Services, segmenti.

1. A cosa serve e perché esiste

Le librerie di `integration-libs/` collegano lo storefront a prodotti SAP che **non** fanno parte del backend Commerce standard e che richiedono addon o servizi cloud dedicati. Questo capitolo copre quattro di esse:

LIBRERIA	SISTEMA ESTERNO	COSA FA NELLO STOREFRONT	MECCANISMO DOMINANTE
`@spartacus/cdc`	SAP Customer Data Cloud (ex Gigya)	Sostituisce login, registrazione, logout, gestione profilo, consensi e (in B2B) amministrazione utenti/unità con le API del Gigya JS SDK; poi ottiene un token OAuth Commerce con `grant_type=custom`	override via DI di guard, adapter, component service; `APP_INITIALIZER`; feature lazy con facade
`@spartacus/cdp`	SAP Customer Data Platform	Rende read-only il customer ticketing (niente chiusura, riapertura, invio messaggi)	override via DI di 3 component service
`@spartacus/cds`	SAP Context-Driven Services (Emarsys/ProfileTag)	Carousel di merchandising da strategie CDS, tracciamento comportamentale con lo script ProfileTag, recent/trending searches	adapter/connector, componenti CMS, `HTTP_INTERCEPTORS`, `APP_INITIALIZER`, outlet
`@spartacus/segment-refs`	segmenti esterni (riferimenti a segmenti per la personalizzazione OCC)	Inoltra all'OCC un header con il riferimento di segmento letto da query param/localStorage	un solo `HTTP_INTERCEPTORS`

Il filo conduttore — e la ragione per cui conviene leggere queste librerie anche se non si usano i prodotti — è che **quasi tutta l'integrazione è fatta sostituendo servizi di core e delle feature lib via Dependency Injection**, senza modificare una riga delle librerie originali. In CDC si trovano tutti gli stili di override che Spartacus offre:

1. **override di un token nel root injector** con `useExisting`/`useClass` (guard di login/logout, `UserConsentAdapter`): integration-libs/cdc/root/cdc-root.module.ts:L53-L69, integration-libs/cdc/root/consent-management/cdc-consent.module.ts:L16-L31;
2. **override "scoped" nell'injector di un singolo componente CMS** tramite `cmsComponents.<Tipo>.providers` (login form, registrazione, profilo): integration-libs/cdc/user-account/login-form/cdc-login-form.module.ts:L44-L68, meccanismo in core-libs/storefront/cms-structure/page/component/services/cms-injector.service.ts:L28-L50;
3. **override nell'injector di una feature lazy** importando il modulo di estensione *dopo* quello originale nel wrapper lazy (`CdcAdministrationModule`, `CdpCustomerTicketingModule`): projects/storefrontapp/src/app/spartacus/features/organization/administration-wrapper.module.ts:L12-L20, projects/storefrontapp/src/app/spartacus/features/customer-ticketing/customer-ticketing-wrapper.module.ts:L13-L22;
4. **override di configurazione** (route semantiche, `authentication.customLoginPage`): integration-libs/cdc/root/config/default-cdc-routing-config.ts:L9-L35, integration-libs/cdc/user-account/login-form/cdc-login-form.module.ts:L44-L48;
5. **estensione per sottoclasse** di classi core con metodi `protected` sovrascritti (`CdcLoginGuard extends LoginGuard`, `CdcUserConsentAdapter extends OccUserConsentAdapter`): integration-libs/cdc/root/guards/cdc-login.guard.ts:L12-L32, integration-libs/cdc/root/consent-management/cdc-user-consent.adapter.ts:L35-L65.

CDS, al contrario, è soprattutto **additivo**: aggiunge interceptor, initializer, componenti CMS e outlet (integration-libs/cds/src/profiletag/profile-tag.module.ts:L16-L32, integration-libs/cds/src/cds.

module.ts:L26-L47), e sostituisce un solo token astratto che è suo (MerchandisingStrategyAdapter, integration-libs/cds/src/merchandising/merchandising.module.ts:L12-L21). CDP e segment-refs sono librerie minime, utili come esempi "da una pagina" di override (integration-libs/cdp/customer-ticketing/cdp-customer-ticketing.module.ts:L17-L35) e di interceptor (integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L69-L86).

Prerequisiti utili: 01 — Dependency Injection, 12 — Feature module e lazy loading, 11 — Configurazione, 20 — Facade, command & query, eventi, 22 — Autenticazione, 16 — CMS rendering.

---

2. Mappa dei file

2.1 integration-libs/cdc

Entry point secondari: @spartacus/cdc (lazy), /root (eager), /core, /components, /user-account, /user-profile, /organization/administration, /organization/user-registration.

PATH	RUOLO
integration-libs/cdc/public_api.ts	esporta solo CdcModule (L7-L7)
integration-libs/cdc/cdc.module.ts	CdcModule = CdcComponentsModule + CdcCoreModule, target del lazy load di CDC_FEATURE
integration-libs/cdc/root/public_api.ts	entry @spartacus/cdc/root
integration-libs/cdc/root/cdc-root.module.ts	CdcRootModule eager: override dei 3 guard, APP_INITIALIZER Gigya, featureModules, routing
integration-libs/cdc/root/feature-name.ts	CDC_FEATURE = 'cdc', CDC_CORE_FEATURE = 'cdcCore'
integration-libs/cdc/root/config/cdc-config.ts	CdcConfig (array cdc[] per base site)
integration-libs/cdc/root/config/default-cdc-routing-config.ts	route cdcLogin, cdcCheckoutLogin, cdcOrgRegistration, ridefinizione login/loginForm
integration-libs/cdc/root/facade/cdc-auth.facade.ts	CdcAuthFacade (facade lazy su cdcCore)
integration-libs/cdc/root/events/cdc-event.ts	CdcLoadUserTokenFailEvent, CdcReConsentEvent
integration-libs/cdc/root/guards/cdc-login.guard.ts	CdcLoginGuard extends LoginGuard
integration-libs/cdc/root/guards/cdc-logout.guard.ts	CdcLogoutGuard extends LogoutGuard
integration-libs/cdc/root/guards/cdc-login-as-guest.guard.ts	CdcLoginAsGuestGuard extends LoginAsGuestGuard
integration-libs/cdc/root/service/cdc-js.service.ts	CdcJsService: carica lo script Gigya e avvolge le sue API callback in Observable
integration-libs/cdc/root/consent-management/cdc-consent.module.ts	override UserConsentAdapter, ConsentManagementComponentService, serializer
integration-libs/cdc/root/consent-management/cdc-user-consent.adapter.ts	CdcUserConsentAdapter extends OccUserConsentAdapter
integration-libs/cdc/root/consent-management/converters/cdc-preference.serializer.ts	CdcPreferenceSerializer (consensi → preferences annidate)
integration-libs/cdc/root/consent-management/converters/converter.ts	token multi CDC_PREFERENCE_SERIALIZER

PATH	RUOLO
integration-libs/cdc/root/consent-management/model/cdc-consent-management.model.ts	augmentation di `LAUNCH_CALLER` e `UserSignUp`
integration-libs/cdc/root/consent-management/services/cdc-consents-local-storage.service.ts	persistenza `cdc-consents-list`
integration-libs/cdc/root/consent-management/services/cdc-consent-management-component.service.ts	consensi obbligatori CDC + core
integration-libs/cdc/root/consent-management/services/cdc-user-consent.service.ts	`updateCdcUserPreferences`
integration-libs/cdc/core/public_api.ts	entry `@spartacus/cdc/core` (store non esportato)
integration-libs/cdc/core/cdc-core.module.ts	`CdcCoreModule`: auth + eventi + store + `facadeProviders`
integration-libs/cdc/core/auth/facade/facade-providers.ts	`CdcAuthFacade → CdcAuthService`
integration-libs/cdc/core/auth/facade/cdc-auth.service.ts	`CdcAuthService`: dispatch, check ASM, scrittura token
integration-libs/cdc/core/auth/services/user-authentication/cdc-user-authentication-token.service.ts	POST token endpoint `grant_type=custom`
integration-libs/cdc/core/store/actions/cdc-user-token.action.ts	`LOAD_CDC_USER_TOKEN(_FAIL)`
integration-libs/cdc/core/store/effects/cdc-user-token.effect.ts	effect token
integration-libs/cdc/core/store/effects/cdc-user-addresses.effect.ts	sincronizzazione indirizzo di default verso CDC
integration-libs/cdc/core/events/cdc-event.builder.ts	azione `LOAD_CDC_USER_TOKEN_FAIL` → evento
integration-libs/cdc/core/models/cms.model.ts	`GigyaRaasComponentData`
integration-libs/cdc/components/gigya-raas/gigya-raas.module.ts	mapping CMS `GigyaRaasComponent` + layout `GigyaLoginPageTemplate`
integration-libs/cdc/components/gigya-raas/gigya-raas.component.ts	componente che mostra gli screen-set Gigya
integration-libs/cdc/components/gigya-raas/gigya-raas.guard.ts	guard CMS (auth/not-auth per componente)
integration-libs/cdc/user-account/login-form/cdc-login-form.module.ts	override scoped del login form + `customLoginPage: undefined`
integration-libs/cdc/user-account/login-form/cdc-login-form-component.service.ts	login via `accounts.login`
integration-libs/cdc/user-account/login-form/reconsent/*	dialog di reconsent (`CDC_RECONSENT`)
integration-libs/cdc/user-profile/cdc-user-profile.module.ts	aggregatore degli override profilo
integration-libs/cdc/user-profile/register/cdc-register.module.ts	override scoped `RegisterComponentService`
integration-libs/cdc/user-profile/register/cdc-register-component.service.ts	registrazione via CDC + consensi aggiuntivi

PATH	RUOLO
integration-libs/cdc/user-profile/{forgot-password,update-email,update-password,update-profile}/*	override scoped dei rispettivi component service
integration-libs/cdc/organization/administration/cdc-administration.module.ts	override B2BUserService, OrgUnitService, UserListService
integration-libs/cdc/organization/administration/cdc-user-list.service.ts	apre il Delegated Admin CDC
integration-libs/cdc/organization/user-registration/cdc-b2b-register.module.ts	override UserRegistrationFormService
integration-libs/cdc/assets/translations/translations.ts	chunk i18n cdc: ['reconsent','cdcProfile']

2.2 integration-libs/cds

PATH	RUOLO
integration-libs/cds/public_api.ts	entry @spartacus/cds (no recent-searches, no services, no utils)
integration-libs/cds/src/cds.module.ts	CdsModule eager + forRoot(config?)

integration-libs/cds/src/profiletag/providers/login-events.provider.ts	`LOGIN_EVENTS` + `provideAppInitializer`
integration-libs/cds/src/profiletag/adapters/occ-backend-notification-adapter.ts	POST `/users/{id}/loginnotification`
integration-libs/cds/src/profiletag/tracking/tracking.module.ts	`APP_INITIALIZER` del tracking
integration-libs/cds/src/profiletag/tracking/tracking.service.ts	filtro per consenso e inoltro
integration-libs/cds/src/recent-searches/recent-searches.module.ts	outlet recent searches
integration-libs/cds/src/trending-searches/trending-searches.module.ts	outlet trending searches
integration-libs/cds/src/trending-searches/trending-searches.service.ts	polling `searchIntelligence`

2.3 `integration-libs/cdp` e `integration-libs/segment-refs`

PATH	RUOLO
integration-libs/cdp/public_api.ts	entry `@spartacus/cdp` → solo `customer-ticketing`
integration-libs/cdp/customer-ticketing/cdp-customer-ticketing.module.ts	override di 3 component service
integration-libs/cdp/customer-ticketing/cdp-customer-ticketing-close-component.service.ts	`enableCloseButton → of(false)`

PATH	RUOLO
integration-libs/cdp/customer-ticketing/cdp-customer-ticketing-reopen-component.service.ts	enableReopenButton → of(false)
integration-libs/cdp/customer-ticketing/cdp-customer-ticketing-messages-component.service.ts	displayAddMessageSection → false
integration-libs/segment-refs/public_api.ts	entry @spartacus/segment-refs
integration-libs/segment-refs/root/segment-refs-root.module.ts	interceptor + default config
integration-libs/segment-refs/root/config/segment-refs-config.ts	SegmentRefsConfig (non esportato)
integration-libs/segment-refs/root/config/default-segment-refs-config.ts	httpHeaderName: 'Segmentrefs'
integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts	OccSegmentRefsInterceptor
integration-libs/segment-refs/root/feature-name.ts	SEGMENT_REFS_FEATURE (inutilizzata)

2.4 Wiring (schematics e demo app)

PATH	RUOLO
core-libs/schematics/src/shared/lib-configs/integration-libs/cdc-schematics-config.ts	root module eager, chunk lazy, importAfter per user/organization
core-libs/schematics/src/shared/lib-configs/integration-libs/cds-schematics-config.ts	CdsModule.forRoot(), endpoint generati, lazy: false
core-libs/schematics/src/shared/lib-configs/integration-libs/cdp-schematics-config.ts	importAfter su CustomerTicketingModule
core-libs/schematics/src/shared/lib-configs/integration-libs/segment-refs-schematics-config.ts	dipendenza da personalization
projects/storefrontapp/src/app/spartacus/features/cdc/cdc-feature.module.ts	CdcRootModule + lazy CdcModule
projects/storefrontapp/src/app/spartacus/features/cds/cds-feature.module.ts	factory config CDS per base site
projects/storefrontapp/src/app/spartacus/features/user/user-account-wrapper.module.ts	CDCUserAccountModule dopo UserAccountModule
projects/storefrontapp/src/app/spartacus/features/organization/administration-wrapper.module.ts	CdcAdministrationModule dopo AdministrationModule
projects/storefrontapp/src/app/spartacus/features/customer-ticketing/customer-ticketing-wrapper.module.ts	CdpCustomerTicketingModule nel wrapper lazy

File aggiuntivi

PATH	RUOLO
integration-libs/cdc/schematics/add-cdc/index.ts	rule ng add di @spartacus/cdc (addCdcFeature)
integration-libs/cdc/schematics/add-cdc/index_spec.ts	test Jest dello schematic CDC: B2C e B2B, validazione di javascriptUrl, lazy/eager
integration-libs/cdc/vitest.config.ts	configurazione Vitest di cdc (restoreMocks: true, coverage solo lcov)
integration-libs/cdp/schematics/add-cdp/index.ts	rule ng add di @spartacus/cdp (addCdpFeature)

PATH	RUOLO
integration-libs/cdp/schematics/add-cdp/index_spec.ts	test Jest dello schematic CDP (richiede prima customer ticketing)
integration-libs/cdp/vitest.config.ts	configurazione Vitest di cdp
integration-libs/cds/vitest.config.ts	configurazione Vitest di cds (soglie 80%)
integration-libs/segment-refs/schematics/add-segment-refs/index.ts	rule `ng add` di `@spartacus/segment-refs` (`addSegmentRefsFeature`)
integration-libs/segment-refs/schematics/add-segment-refs/index_spec.ts	test Jest dello schematic segment-refs (richiede prima personalization)
integration-libs/segment-refs/vitest.config.ts	configurazione Vitest di segment-refs (soglie 90/90/75/90)

3. Come funziona passo per passo

3.1 CDC: struttura root/lazy

CDC segue la convenzione root/lazy descritta in 12 — Feature module e lazy loading, con una particolarità: il root module non è affatto "leggero".

1. **Nomi delle feature.** `CDC_FEATURE = 'cdc'` e `CDC_CORE_FEATURE = 'cdcCore'` — integration-libs/cdc/root/feature-name.ts:L7-L8.
2. **Config CMS di default.** `defaultCdcComponentsConfig` dichiara che la feature `cdc` possiede il componente CMS `GigyaRaasComponent` e che `cdcCore` è un **alias stringa** di `cdc` ("by default core is bundled together with components") — integration-libs/cdc/root/cdc-root.module.ts:L40-L51. L'alias è risolto da `FeatureModulesService.resolveFeatureAlias`, che segue la catena finché il valore è una stringa — core-libs/core/src/lazy-loading/feature-modules.service.ts:L95-L100.
3. **Modulo lazy.** `CdcModule` importa `CdcComponentsModule` e `CdcCoreModule` — integration-libs/cdc/cdc.module.ts:L7-L14. Nella demo app `CdcFeatureModule` importa `CdcRootModule` e registra `module: () => import('@spartacus/cdc').then((m) => m.CdcModule)` — projects/storefrontapp/src/app/spartacus/features/cdc/cdc-feature.module.ts:L17-L40.
4. **Root module eager.** `CdcRootModule` importa `CdcConsentManagementModule` e fornisce: config CMS, tre override di guard con `useExisting`, un `APP_INITIALIZER` e la routing config — integration-libs/cdc/root/cdc-root.module.ts:L53-L69.
5. **Facade lazy.** `CdcAuthFacade` è una classe astratta `providedIn: 'root'` con `useFactory: () => facadeFactory({ facade, feature: CDC_CORE_FEATURE, methods: ['loginWithCustomCdcFlow','loginWithToken'], async: true })` — integration-libs/cdc/root/facade/cdc-auth.facade.ts:L11-L33. Con `async: true` il resolver aggiunge `delay(0)` e ogni chiamata di metodo è resa *eager* con `connectable(...).connect()` su `ReplaySubject`: il metodo reale viene invocato anche se il chiamante non si sottoscrive — core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L53-L56, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L70-L82. Quando il modulo lazy è caricato, `facadeProviders` lega la facade a `CdcAuthService` con `useExisting` — integration-libs/cdc/core/auth/facade/facade-providers.ts:L11-L17.
6. **Core lazy.** `CdcCoreModule` importa `CdcAuthModule`, `CdcEventModule`, `CdcStoreModule` — integration-libs/cdc/core/cdc-core.module.ts:L13-L17; lo store registra `EffectsModule.forFeature(effects)` — integration-libs/cdc/core/store/cdc-store.module.ts:L14-L18 — con `CdcUserTokenEffects` e `CdcUserAddressesEffects` — integration-libs/cdc/core/store/effects/index.ts:L10-L10.

Conseguenza: tutto ciò che deve esistere **prima** del primo login (guard, script Gigya, consensi, `CdcJsService`) sta nel root; la parte NgRx che produce il token Commerce è lazy e viene scaricata alla prima chiamata della facade.

3.2 CDC: bootstrap dello script Gigya

1. `cdcJsFactory` restituisce una funzione che ritorna `lastValueFrom(configInit.getStable('context', 'cdc').pipe(tap(() => cdcJsService.initialize())))` — integration-libs/cdc/root/cdc-root.module.ts:L26-L38. Il token `APP_INITIALIZER` è deprecato da Angular v19 a favore di `provideAppInitializer` — angular:packages/core/src/application/application_init.ts:L38-L38.
2. `getStable(...scopes)` emette subito se la config è già stabile, altrimenti attende che nessuno scope in corso si sovrapponga a quelli richiesti — core-libs/core/src/config/config-initializer/config-initializer.service.ts:L58-L70. Tra gli initializer di core con scope dichiarati ci sono quelli di site context (`['context']`), i18n (`['i18n.fallbackLang']`), auth (`['authentication.OAuthLibConfig.redirectUri', 'authentication.client_id']`) e secure portal (`['routing']`); nessuno si sovrappone a `'cdc'` — core-libs/core/src/site-context/config/config-loader/site-context-config-initializer.ts:L26-L26, core-libs/core/src/i18n/config/i18n-config-initializer.ts:L16-L16, core-libs/core/src/auth/user-auth/config/auth-config-initializer.ts:L20-L23, core-libs/core/src/routing/configurable-routes/secure-portal-config/secure-portal-config-initializer.ts:L18-L18; `scopesOverlap` usa il confronto per prefisso puntato — core-libs/core/src/config/config-initializer/config-initializer.service.ts:L117-L122. Quindi lo scope `'cdc'` serve solo se l'applicazione registra un proprio initializer con quello scope (nessuno nel repo: vedi §9).
3. `loadCdcJavascript` agisce **solo in browser** (`isPlatformBrowser`), prende il primo valore di base site e lingua attivi (`take(1)`) — integration-libs/cdc/root/service/cdc-js.service.ts:L94-L103.
4. La config per base site si sceglie filtrando `cdcConfig.cdc` per `baseSite` e prendendo il primo elemento; senza corrispondenza ritorna `''` e nessuno script viene caricato — integration-libs/cdc/root/service/cdc-js.service.ts:L141-L149.
5. L'URL è `javascriptUrl&lang=<lingua>`, iniettato con `ScriptLoader.embedScript`. Al `load` registra gli handler Gigya, scarica i consensi del sito persistendoli in local storage ed emette `loaded$ = true`; all'errore `errorLoading$ = true` — integration-libs/cdc/root/service/cdc-js.service.ts:L104-L122. Poi imposta `window.__gigyaConf = { include: 'id_token, missing-required-fields, preferences' }` — integration-libs/cdc/root/service/cdc-js.service.ts:L123-L129.
6. `ScriptLoader.embedScript` in SSR non accetta callback, e in browser non reinserisce uno script già presente — core-libs/core/src/util/script-loader.service.ts:L55-L61, core-libs/core/src/util/script-loader.service.ts:L84-L89.
7. `addCdcEventHandlers` legge `window.gigya` e registra `onLogin`, eseguito dentro `zone.run` (le callback del SDK arrivano fuori dalla zona Angular) — integration-libs/cdc/root/service/cdc-js.service.ts:L165-L173.

`CdcJsService` conserva `loaded$` ed `errorLoading$` come `ReplaySubject(1)` — integration-libs/cdc/root/service/cdc-js.service.ts:L43-L52 — esposti come `didLoad()` / `didScriptFailToLoad()` e consumati da componenti e component service (es. integration-libs/cdc/components/gigya-raas/gigya-raas.component.ts:L27-L59).

3.3 CDC: il ponte `invokeAPI` verso il Gigya SDK

Tutte le operazioni "without screen-set" passano per un unico metodo:

1. `getSdkFunctionFromName` scende in `gigyaSDK` lungo i segmenti del nome puntato (`accounts.setAccountInfo`) con `hasOwnProperty`; un segmento mancante viene saltato — integration-libs/cdc/

root/service/cdc-js.service.ts:L713-L726.

2. `invokeAPI` crea un Observable **cold** (`new Observable`), chiama `actualAPI({...payload, callback})` e nella callback, dentro `zone.run`, emette `next + complete` se `status === 'OK'`, altrimenti `error(response)` — integration-libs/cdc/root/service/cdc-js.service.ts:L734-L755.

Su questo ponte sono costruiti:

METODO DI CDCJSSERVICE	API GIGYA	RIFERIMENTO
`registerUserWithoutScreenSet`	`accounts.initRegistration` → `accounts.register` (`finalizeRegistration: true`)	integration-libs/cdc/root/service/cdc-js.service.ts:L199-L243
`loginUserWithoutScreenSet`	`accounts.login` (`ignoreInterruptions` solo se canale `B2C`, `sessionExpiry`)	integration-libs/cdc/root/service/cdc-js.service.ts:L252-L292
`registerOrganisationWithoutScreenSet`	`accounts.b2b.registerOrganization`	integration-libs/cdc/root/service/cdc-js.service.ts:L299-L344
`getOrganizationContext`	`accounts.b2b.getOrganizationContext`	integration-libs/cdc/root/service/cdc-js.service.ts:L350-L352
`openDelegatedAdminLogin` (chiamata diretta al SDK dentro `zone.run`, **non** via `invokeAPI`)	`accounts.b2b.openDelegatedAdminLogin`	integration-libs/cdc/root/service/cdc-js.service.ts:L359-L365
`resetPasswordWithoutScreenSet`	`accounts.resetPassword`	integration-libs/cdc/root/service/cdc-js.service.ts:L460-L494
`updateProfileWithoutScreenSet`	`accounts.setAccountInfo` (+ update Commerce)	integration-libs/cdc/root/service/cdc-js.service.ts:L502-L528
`updateUserPasswordWithoutScreenSet`	`accounts.setAccountInfo` (`password`, `newPassword`)	integration-libs/cdc/root/service/cdc-js.service.ts:L536-L557
`updateUserEmailWithoutScreenSet`	`accounts.login` con `skipOccAuth` + `setAccountInfo`	integration-libs/cdc/root/service/cdc-js.service.ts:L635-L650
`updateAddressWithoutScreenSet`	`accounts.setAccountInfo` (`profile.address`, …)	integration-libs/cdc/root/service/cdc-js.service.ts:L687-L706
`getSiteConsentDetails`	`accounts.getSiteConsentDetails` (apikey dalla query di `javascriptUrl`)	integration-libs/cdc/root/service/cdc-js.service.ts:L762-L782
`setUserConsentPreferences`	`accounts.setAccountInfo` (`preferences`, `regToken`)	integration-libs/cdc/root/service/cdc-js.service.ts:L792-L812

Il caso più curioso è l'update email: "CDC doesn't have any specific api, for verifying a password", quindi il codice chiama `loginUserWithoutScreenSet(email, password, { skipOccAuth: true })` come verifica e poi `setAccountInfo` — integration-libs/cdc/root/service/cdc-js.service.ts:L635-L650. Il flag `skipOccAuth` arriva nel `context` della risposta `onLogin` ed evita il ri-login su Commerce — integration-libs/cdc/root/service/cdc-js.service.ts:L181-L192.

3.4 CDC: dal login Gigya al token OAuth Commerce

1. **Origine del login.** O lo screen-set Gigya (`GigyaRaasComponent.showScreenSet` → `gigya.accounts.showScreenSet`, integration-libs/cdc/components/gigya-raas/gigya-raas.component.ts:L80-L105) o il form Spartacus (`CdcLoginFormComponentService.login` → `loginUserWithoutScreenSet`, integration-libs/cdc/user-account/login-form/cdc-login-form-component.service.ts:L34-L66).
2. `onLogin` **di Gigya** → `onLoginEventHandler` chiama `cdcAuth.loginWithCustomCdcFlow(UID, UIDSignature, signatureTimestamp, id_token || '', baseSite)` salvo `skipOccAuth` — integration-libs/cdc/root/service/cdc-js.service.ts:L181-L192.
3. **Facade → lazy load.** La facade risolve `cdcCore` → alias `cdc` → carica `CdcModule` — integration-libs/cdc/root/facade/cdc-auth.facade.ts:L11-L33, core-libs/core/src/lazy-loading/feature-modules.service.ts:L95-L100.
4. **Dispatch.** `CdcAuthService.loginWithCustomCdcFlow` dispatcha `LoadCdcUserToken` — integration-libs/cdc/core/auth/facade/cdc-auth.service.ts:L47-L63; azione `'[Auth] Load CDC User Token'` — integration-libs/cdc/core/store/actions/cdc-user-token.action.ts:L10-L41.
5. **Effect.** `CdcUserTokenEffects.loadCdcUserToken$` chiama `loadTokenUsingCustomFlow` — integration-libs/cdc/core/store/effects/cdc-user-token.effect.ts:L25-L59 — che fa POST al token endpoint OAuth con `grant_type=custom`, `client_id`, `client_secret` e i campi CDC URL-encoded — integration-libs/cdc/core/auth/services/user-authentication/cdc-user-authentication-token.service.ts:L43-L60.
6. **Successo.** L'effect chiama `cdcAuthService.loginWithToken(token)` e ritorna `EMPTY` — integration-libs/cdc/core/store/effects/cdc-user-token.effect.ts:L40-L43. `loginWithToken` verifica prima che non ci sia un agente ASM loggato (se lo storage è un `AsmAuthStorageService` con token di tipo `CSAgent`, mostra `asm.auth.agentLoggedInError`) — integration-libs/cdc/core/auth/facade/cdc-auth.service.ts:L68-L104; poi `setTokenData`, `setUserId(OCC_USER_ID_CURRENT)`, `AuthActions.Login()`, rimozione errori globali e `authRedirectService.redirect()` — integration-libs/cdc/core/auth/facade/cdc-auth.service.ts:L106-L120.
7. **Formato token.** `setTokenData` scrive nello `AuthStorageService` le stesse chiavi che userebbe la libreria OAuth: `access_token`, `granted_scopes`, `access_token_stored_at`, `expires_at`, `refresh_token` — integration-libs/cdc/core/auth/facade/cdc-auth.service.ts:L123-L145. Da qui in poi il resto dello storefront (interceptor, refresh) vede un utente normalmente autenticato: vedi 22 — Autenticazione.
8. **Errore.** Messaggio `httpHandlers.badGateway` e azione `LoadCdcUserTokenFail` — integration-libs/cdc/core/store/effects/cdc-user-token.effect.ts:L44-L55 — che `CdcEventBuilder` trasforma in `CdcLoadUserTokenFailEvent` via `StateEventService.register` — integration-libs/cdc/core/events/cdc-event.builder.ts:L33-L38.

DA VERIFICARE: quale estensione lato Commerce accetti `grant_type=custom` con questi parametri; il codice Spartacus non lo dichiara (dossier Q1).

3.5 CDC: override dei guard di login/logout

GUARD CORE	OVERRIDE CDC	COSA CAMBIA	RIFERIMENTO
`LoginGuard` (storefront)	`CdcLoginGuard`	`shouldRenderCMSPage()` → sempre `of(true)`: la pagina CMS di login è sempre mostrata e non si fa mai `loginWithRedirect()` verso il server OAuth	integration-libs/cdc/root/guards/cdc-login.guard.ts:L12-L32; base core-libs/storefront/cms-components/user/login-route/login.guard.ts:L34-L65

GUARD CORE	OVERRIDE CDC	COSA CAMBIA	RIFERIMENTO
`LogoutGuard` (storefront)	`CdcLogoutGuard`	`logout()` esegue in parallelo `super.logout()` (`auth.coreLogout()`) e `gigya.accounts.logout()`	integration-libs/cdc/root/guards/cdc-logout.guard.ts:L43-L55; base core-libs/storefront/cms-components/user/logout/logout.guard.ts:L87-L89
`LoginAsGuestGuard` (user/account/components)	`CdcLoginAsGuestGuard`	`getPath()` usa la route `login` invece di `loginForm`	integration-libs/cdc/root/guards/cdc-login-as-guest.guard.ts:L10-L17; base feature-libs/user/account/components/guards/login-as-guest.guard.ts:L26-L28

Gli override funzionano perché le route non referenziano la classe concreta ma il token: `canActivate: [LoginGuard]` — core-libs/storefront/cms-components/user/login-route/login-route.module.ts:L29-L29; `canActivate: [LogoutGuard, CmsPageGuard]` — core-libs/storefront/cms-components/user/logout/logout.module.ts:L25-L25; `guards: [NotAuthGuard, LoginAsGuestGuard]` nel componente login-register — feature-libs/user/account/components/login-register/login-register.module.ts:L37-L37. Il cambio di path in `CdcLoginAsGuestGuard` è coerente con la routing config CDC, che svuota `loginForm.paths` "to avoid same path in different routes" — integration-libs/cdc/root/config/default-cdc-routing-config.ts:L9-L35.

3.6 CDC: override "scoped" dei component service

I moduli `CDCLoginFormModule`, `CDCRegisterModule`, `CDCForgotPasswordModule`, `CDCUpdateProfileModule`, `CDCUpdatePasswordModule`, `CDCUpdateEmailModule` non toccano il root injector: aggiungono `providers` alla mappatura CMS del componente.

1. `CDCLoginFormModule` imposta `authentication.customLoginPage: undefined` e ridefinisce `ReturningCustomerLoginComponent` con `guards: [NotAuthGuard]` e il provider `LoginFormComponentService → CdcLoginFormComponentService` con `deps` espliciti — integration-libs/cdc/user-account/login-form/cdc-login-form.module.ts:L44-L68.
2. `CmsInjectorService.getInjector` crea per ogni istanza di componente un `Injector.create` figlio con quei provider (parent = injector del modulo/feature) — core-libs/storefront/cms-structure/page/component/services/cms-injector.service.ts:L28-L50. L'override vale **solo** nell'albero di quel componente.
3. Il default di user/account per lo stesso componente ha `guards: [NotAuthGuard, CustomLoginGuard]` — feature-libs/user/account/components/login-form/login-form.module.ts:L52-L59. Siccome `deepMerge` sostituisce gli array (ramo `else`) — core-libs/core/src/config/utils/deep-merge.ts:L36-L45 — l'override CDC rimuove `CustomLoginGuard`. Allo stesso modo `customLoginPage: undefined` sovrascrive il default `{ csrfEndpoint: '/csrf', loginFormEndpoint: '/login' }` e fa ritornare `false` a `customLoginEnabled()` — core-libs/core/src/auth/user-auth/config/default-auth-config.ts:L65-L68, core-libs/core/src/auth/user-auth/services/auth-config.service.ts:L105-L107.
4. `CdcLoginFormComponentService.login()` attende `didLoad()`, poi `loginUserWithoutScreenSet(userId.toLowerCase(), password)`; se lo script non c'è mostra `errorHandlers.scriptFailedToLoad` — integration-libs/cdc/user-account/login-form/cdc-login-form-component.service.ts:L34-L66. `initCustomLogin()` è sovrascritto vuoto "so csrf token is not initialized in case of CDC" — integration-libs/cdc/user-account/login-form/cdc-login-form-component.service.ts:L68-L70; nel servizio base è invocato dal costruttore con `authorizationCodeFlowByDefault` — feature-libs/user/account/components/login-form/login-form-component.service.ts:L89-L91.
5. `CDCRegisterModule` aggiunge a `RegisterCustomerComponent` solo `providers: [RegisterComponentService → CDCRegisterComponentService]`, lasciando `component`/`guards` del default — integration-libs/cdc/user-

profile/register/cdc-register.module.ts:L38-L51. Lo stesso schema per `ForgotPasswordComponent`, `UpdateProfileComponent`, `UpdatePasswordComponent`, `UpdateEmailComponent` — integration-libs/cdc/user-profile/forgot-password/cdc-forgot-password.module.ts:L35-L47, integration-libs/cdc/user-profile/update-profile/cdc-update-profile.module.ts:L39-L52, integration-libs/cdc/user-profile/update-password/cdc-update-password.module.ts:L37-L50, integration-libs/cdc/user-profile/update-email/cdc-update-email.module.ts:L37-L50.

6. `CDCRegisterComponentService.register` attende il load di CDC, esegue un `Command` che chiama `registerUserWithoutScreenSet`, attende `merge(loadUserTokenFailed$, isLoggedIn$)` e poi aggiorna il profilo Commerce — integration-libs/cdc/user-profile/register/cdc-register-component.service.ts:L43-L123. Il form di registrazione aggiunge i consensi CDC attivi (con `Validators.requiredTrue` per gli obbligatori) e li serializza in `preferences` — integration-libs/cdc/user-profile/register/cdc-register-component.service.ts:L134-L215. `postRegisterMessage()` è svuotato — integration-libs/cdc/user-profile/register/cdc-register-component.service.ts:L125-L128.

3.7 CDC: consensi

1. `CdcConsentManagementModule` (importato dal root, quindi eager) sostituisce `UserConsentAdapter` con `CdcUserConsentAdapter`, `ConsentManagementComponentService` con `CdcConsentManagementComponentService` e registra `CdcPreferenceSerializer` nel token multi `CDC_PREFERENCE_SERIALIZER` — integration-libs/cdc/root/consent-management/cdc-consent.module.ts:L16-L31. Il default è `OccUserConsentAdapter` in `UserOccModule` — core-libs/core/src/occ/adapters/user/user-occ.module.ts:L39-L39.
2. All'avvio dello script, `getSiteConsentDetails(true)` persiste i consensi del sito: `CdcConsentsLocalStorageService` salva in `StatePersistenceService` (chiave `cdc-consents-list`) solo quelli `isActive === true`, con `required = isMandatory` — integration-libs/cdc/root/consent-management/services/cdc-consents-local-storage.service.ts:L15-L51.
3. `CdcUserConsentAdapter.giveConsent`: delega a OCC se la lista CDC in storage esiste e non contiene l'id; se la lista non è mai stata persistita, `readFromStorage` ritorna `undefined` e `checkIfConsentExists` lancia `TypeError` (né OCC né CDC vengono chiamati) — integration-libs/cdc/root/consent-management/services/cdc-consents-local-storage.service.ts:L57-L76, core-libs/core/src/state/utils/browser-storage.ts:L65-L68; altrimenti aggiorna prima le preferenze CDC e chiama l'OCC solo con `errorCode === 0`, altrimenti `EMPTY` — integration-libs/cdc/root/consent-management/cdc-user-consent.adapter.ts:L35-L65. `withdrawConsent` usa il terzo parametro `consentId` — integration-libs/cdc/root/consent-management/cdc-user-consent.adapter.ts:L67-L89 — che il connector core passa già, anche se `OccUserConsentAdapter.withdrawConsent` ne dichiara solo due — core-libs/core/src/user/connectors/consent/user-consent.connector.ts:L39-L39, core-libs/core/src/occ/adapters/user/occ-user-consent.adapter.ts:L69-L69.
4. `CdcUserConsentService.updateCdcUserPreferences` serializza con `CDC_PREFERENCE_SERIALIZER`, usa uid e lingua attivi, e chiama `setUserConsentPreferences` — integration-libs/cdc/root/consent-management/services/cdc-user-consent.service.ts:L34-L65. Il serializer trasforma `[{id:'terms.marketing', isConsentGranted:true}]` in `{ terms: { marketing: { isConsentGranted: true } } }` con `reduceRight` + `deepMerge` — integration-libs/cdc/root/consent-management/converters/cdc-preference.serializer.ts:L18-L38; `ConverterService.convert` applica in catena tutti i converter del token — core-libs/core/src/util/converter.service.ts:L106-L112, core-libs/core/src/util/converter.service.ts:L130-L137.
5. `CdcConsentManagementComponentService.getRequiredConsents` unisce gli obbligatori core con quelli CDC — integration-libs/cdc/root/consent-management/services/cdc-consent-management-component.service.ts:L20-L52.

Reconsent al login. Se `accounts.login` risponde con errore `206001`, `loginUserWithoutScreenSet` non mostra un errore ma chiama `raiseCdcReconsentEvent` — integration-libs/cdc/root/service/cdc-js.service.ts:L252-L292 — che normalizza gli id (`preferences.X.isConsentGranted` → `X`) e dispatcha `CdcReConsentEvent`

— integration-libs/cdc/root/service/cdc-js.service.ts:L823-L848. CdcReconsentModule istanzia nel costruttore CdcReconsentDialogEventListener — integration-libs/cdc/user-account/login-form/reconsent/cdc-reconsent.module.ts:L21-L41 — che apre il dialog LAUNCH_CALLER.CDC_RECONSENT — integration-libs/cdc/user-account/login-form/reconsent/cdc-reconsent-dialogue-event.listener.ts:L25-L51. Il valore dell'enum è aggiunto per augmentation e assegnazione runtime — integration-libs/cdc/root/consent-management/model/cdc-consent-management.model.ts:L9-L26 — e configurato come DIALOG_TYPE.DIALOG con inlineRoot: true — integration-libs/cdc/user-account/login-form/reconsent/default-cdc-reconsent-layout.config.ts:L10-L18. Alla conferma, savePreferencesAndLogin aggiorna le preferenze con regToken e, se errorCode === 0, ripete il login e chiude il dialog — integration-libs/cdc/user-account/login-form/reconsent/cdc-reconsent-component.service.ts:L32-L75.

3.8 CDC: componente GigyaRaas e guard

1. GigyaRaasModule mappa GigyaRaasComponent con guards: [GigyaRaasGuard] e definisce il layout GigyaLoginPageTemplate (BodyContent, BottomContent) — integration-libs/cdc/components/gigya-raas/gigya-raas.module.ts:L14-L35.
2. Il componente ri-renderizza lo screen-set ad ogni cambio lingua (distinctUntilChanged + renderScreenSet = true) — integration-libs/cdc/components/gigya-raas/gigya-raas.component.ts:L27-L59. In modalità embed (embed === 'true' e containerID non vuoto) mostra lo screen-set inline, altrimenti un link popup — integration-libs/cdc/components/gigya-raas/gigya-raas.component.ts:L141-L147, integration-libs/cdc/components/gigya-raas/gigya-raas.component.html:L1-L24.
3. showScreenSet passa sessionExpiration per gli screen-set di login, e per quelli di profile edit aggancia onSubmit (che calcola isPasswordReset) e onAfterSubmit, che passa i parametri a onProfileUpdateEventHandler aggiungendo in coda l'**oggetto** { passwordReset } — integration-libs/cdc/components/gigya-raas/gigya-raas.component.ts:L80-L105, integration-libs/cdc/components/gigya-raas/gigya-raas.component.ts:L97-L101. onProfileUpdateEventHandler aggiorna l'utente Commerce e fa logout se currentEmail !== userDetails.uid || isPasswordReset — integration-libs/cdc/root/service/cdc-js.service.ts:L564-L609. Siccome il secondo parametro è tipizzato boolean ma riceve un oggetto (sempre truthy), con un evento a un solo argomento il logout scatta a ogni profile edit, non solo quando cambia l'email o si resetta la password. DA VERIFICARE: il numero di argomenti passati da Gigya a onAfterSubmit dipende dal Gigya SDK, che non è nel repo (con più argomenti il secondo parametro sarebbe comunque un argomento Gigya, non il flag).
4. GigyaRaasGuard legge la prossima page context, trova i componenti GigyaRaasComponent della pagina e applica AuthGuard se showAnonymous === 'false' o NotAuthGuard se showLoggedIn === 'false' — integration-libs/cdc/components/gigya-raas/gigya-raas.guard.ts:L38-L78, integration-libs/cdc/components/gigya-raas/gigya-raas.guard.ts:L80-L122.

3.9 CDC: B2B (organization)

1. CdcAdministrationModule sostituisce B2BUserService e OrgUnitService sia come provider di modulo (useClass) sia nei provider CMS di ManageUsersListComponent (+ UserListService → CdcUserListService) e ManageUnitsListComponent, **riaccodando** i provider originali — integration-libs/cdc/organization/administration/cdc-administration.module.ts:L23-L62. Il riaccodamento serve perché l'array providers sostituirebbe quello di default (ListService, ItemService) — feature-libs/organization/administration/components/user/user.config.ts:L42-L53.
2. CdcB2BUserService.isUpdatingUserAllowed() e CdcOrgUnitService.isUpdatingUnitAllowed() ritornano false — integration-libs/cdc/organization/administration/cdc-b2b-user.service.ts:L12-L16, integration-libs/cdc/organization/administration/cdc-org-unit.service.ts:L12-L16 — e il flag è letto da UserGuard e UserDetailsComponent — feature-libs/organization/administration/core/guards/user.

guard.ts:L26-L27, feature-libs/organization/administration/components/user/details/user-details.component.ts:L62-L62.

3. CdcUserListService.onCreateButtonClick legge l'organizzazione con getOrganizationContext e apre il Delegated Admin CDC; il pulsante diventa CreateButtonType.BUTTON — integration-libs/cdc/organization/administration/cdc-user-list.service.ts:L39-L75.
4. CDCB2BRegisterModule sostituisce UserRegistrationFormService con CDCB2BRegisterComponentService — integration-libs/cdc/organization/user-registration/cdc-b2b-register.module.ts:L33-L38 — che registra l'organizzazione via CDC, mostra il messaggio, redirige al login e resetta il form — integration-libs/cdc/organization/user-registration/cdc-b2b-register-component.service.ts:L110-L131. Per il dominio B2B vedi 28 — B2B: organization.

3.10 CDC: wiring

Lo schematic installa CdcRootModule eager, usa CDC_FEATURE come chunk lazy e inserisce CDCUserAccountModule/CDCUserProfileModule (più CdcAdministrationModule/CDCB2BRegisterModule in B2B) con importAfter rispetto ai moduli originali — core-libs/schematics/src/shared/lib-configs/integration-libs/cdc-schematics-config.ts:L55-L101, core-libs/schematics/src/shared/lib-configs/integration-libs/cdc-schematics-config.ts:L126-L136; la config generata ha placeholder BASE_SITE_PLACEHOLDER, JS_SDK_URL_PLACEHOLDER e sessionExpiration 3600 — core-libs/schematics/src/shared/lib-configs/integration-libs/cdc-schematics-config.ts:L161-L171. Nella demo app le estensioni sono importate nei wrapper lazy *dopo* il modulo originale, condizionate da environment.cdc — projects/storefrontapp/src/app/spartacus/features/user/user-account-wrapper.module.ts:L13-L22, projects/storefrontapp/src/app/spartacus/features/organization/administration-wrapper.module.ts:L12-L20.

3.11 CDP: customer ticketing in sola lettura

1. Il pacchetto esporta solo customer-ticketing (tre servizi e un modulo; niente config/adapter) — integration-libs/cdp/public_api.ts:L7-L7, integration-libs/cdp/customer-ticketing/public_api.ts:L7-L10.
2. CdpCustomerTicketingModule sostituisce a livello di modulo CustomerTicketingCloseComponentService, CustomerTicketingReopenComponentService, CustomerTicketingMessagesComponentService — integration-libs/cdp/customer-ticketing/cdp-customer-ticketing.module.ts:L17-L35.
3. Le varianti ritornano of(false) / false — integration-libs/cdp/customer-ticketing/cdp-customer-ticketing-close-component.service.ts:L12-L16, integration-libs/cdp/customer-ticketing/cdp-customer-ticketing-reopen-component.service.ts:L12-L16, integration-libs/cdp/customer-ticketing/cdp-customer-ticketing-messages-component.service.ts:L12-L16.
4. I servizi base sono @Injectable() forniti nei moduli dei componenti — feature-libs/customer-ticketing/components/details/customer-ticketing-close/customer-ticketing-close.module.ts:L44-L45 — e consumati dai componenti — feature-libs/customer-ticketing/components/details/customer-ticketing-close/customer-ticketing-close.component.ts:L36-L37.
5. Lo schematic importa CdpCustomerTicketingModule dopo CustomerTicketingModule (importAfter) — core-libs/schematics/src/shared/lib-configs/integration-libs/cdp-schematics-config.ts:L28-L40; nella demo app avviene nel wrapper lazy — projects/storefrontapp/src/app/spartacus/features/customer-ticketing/customer-ticketing-wrapper.module.ts:L13-L22. Per la feature base vedi 31 — Quote, customer ticketing, subscription billing.

3.12 CDS: modulo, configurazione, endpoint

1. `CdsModule` importa **eager** `ProfileTagModule`, `TrackingModule`, `MerchandisingModule`, `RecentSearchesModule`, `TrendingSearchesModule`; `forRoot(config?)` aggiunge default config factory, la config passata, il validator e `ProfileTagPushEventsService`. Non esiste root module né feature lazy — integration-libs/cds/src/cds.module.ts:L26-L47. Lo schematic importa `CdsModule.forRoot()` e forza `lazy: false` — core-libs/schematics/src/shared/lib-configs/integration-libs/cds-schematics-config.ts:L46-L46, core-libs/schematics/src/shared/lib-configs/integration-libs/cds-schematics-config.ts:L120-L120.
2. `CdsConfig.cds` ha `baseSite?`, `tenant`, `baseUrl`, `consentTemplateId`, `endpoints`, `merchandising`, `profileTag` — integration-libs/cds/src/config/cds-config.ts:L13-L31; i default **non** includono `endpoints` — integration-libs/cds/src/config/default-cds-config.ts:L9-L23.
3. `cdsConfigValidator` richiede `tenant`, `baseUrl`, `endpoints.strategyProducts` e, se c'è `profileTag`, `configUrl`/`javascriptUrl` — integration-libs/cds/src/config/cds-config-validator.ts:L9-L44; i validator girano solo in dev mode e producono solo `logger.warn` — core-libs/core/src/config/config-validator/config-validator.module.ts:L29-L33, core-libs/core/src/config/config-validator/config-validator.ts:L43-L45.
4. `CdsEndpointsService.getUrl` risolve la chiave in `cds.endpoints`, aggiunge `tenant` se assente, URL-encoda, sostituisce `${...}` con `DynamicTemplate`, gestisce i query param ed infine prefissa `baseUrl` — integration-libs/cds/src/services/cds-endpoints.service.ts:L18-L65, senza duplicarlo — integration-libs/cds/src/services/cds-endpoints.service.ts:L67-L81. `DynamicTemplate.resolve` usa una RegExp globale per variabile — integration-libs/cds/src/utils/dynamic-template.ts:L7-L18.
5. Lo schematic genera `strategyProducts` (`/strategy/${tenant}/strategies/${strategyId}/products` o, con `sciEnabled`, `/strategy/v1/sites/${baseSite}/strategies/${strategyId}/products`) e `searchIntelligence` — core-libs/schematics/src/shared/lib-configs/integration-libs/cds-schematics-config.ts:L73-L79.

3.13 CDS: merchandising carousel

1. `MerchandisingModule` lega `MerchandisingStrategyAdapter → CdsMerchandisingStrategyAdapter` e importa il modulo CMS del carousel — integration-libs/cds/src/merchandising/merchandising.module.ts:L12-L21. L'adapter astratto (senza `@Injectable`) e il connector `providedIn: 'root'` seguono lo schema descritto in 21 — Livello OCC — integration-libs/cds/src/merchandising/connectors/strategy/merchandising-strategy.adapter.ts:L11-L21, integration-libs/cds/src/merchandising/connectors/strategy/merchandising-strategy.connector.ts:L13-L28.
2. Il componente CMS `MerchandisingCarouselComponent` — integration-libs/cds/src/merchandising/cms-components/merchandising-carousel-cms.module.ts:L25-L33 — carica i prodotti al cambio di `strategy`, imposta le CSS custom property di colore e con `using()` attiva il flusso di intersection — integration-libs/cds/src/merchandising/cms-components/merchandising-carousel/merchandising-carousel.component.ts:L68-L133.
3. `CdsMerchandisingProductService.loadProductsForStrategy` combina site context e user context (`debounceTime(0)`) in una `StrategyRequest` — integration-libs/cds/src/merchandising/facade/cds-merchandising-product.service.ts:L29-L66. Il site context è `{site, language}` — integration-libs/cds/src/merchandising/facade/cds-merchandising-site-context.service.ts:L22-L35; lo user context unisce consent reference (se consenso dato), prodotto (PDP) o categoria (PLP), facet e testo di ricerca — integration-libs/cds/src/merchandising/facade/cds-merchandising-user-context.service.ts:L40-L122.
4. L'adapter in SSR ritorna `{ products: [] }`; in browser fa GET su `strategyProducts` con header `consent-reference` — integration-libs/cds/src/merchandising/adapters/strategy/cds-merchandising-strategy.adapter.ts:L30-L61.

5. Ogni prodotto è caricato con `ProductService.get(id, [DETAILS, PRICE])` e arricchito con metadata `slot/id` — integration-libs/cds/src/merchandising/cms-components/merchandising-carousel/merchandising-carousel.component.service.ts:L152-L170, integration-libs/cds/src/merchandising/cms-components/merchandising-carousel/merchandising-carousel.component.service.ts:L193-L203.
6. La soglia di visibilità è `viewportPercentage` del CMS, poi `cds.merchandising.defaultCarouselViewportThreshold`, poi `80` — integration-libs/cds/src/merchandising/cms-components/merchandising-carousel/merchandising-carousel.component.service.ts:L44-L53. `CarouselViewed` (deduplicato per id modello) e `CarouselClicked` sono push event per ProfileTag — integration-libs/cds/src/merchandising/cms-components/merchandising-carousel/merchandising-carousel.component.service.ts:L93-L133, integration-libs/cds/src/merchandising/cms-components/merchandising-carousel/model/merchandising-carousel-events.model.ts:L17-L44.
7. I metadata finiscono nel DOM come `data-cx-merchandising-*` tramite `AttributesDirective` — integration-libs/cds/src/merchandising/cms-components/merchandising-carousel/merchandising-carousel.component.html:L4-L21, integration-libs/cds/src/merchandising/cms-components/directives/attributes/attributes.directive.ts:L29-L47.

3.14 CDS: ProfileTag e tracking

1. `ProfileTagModule` aggiunge due `HTTP_INTERCEPTORS` (`ConsentReferenceInterceptor`, `DebugInterceptor`), lega `CdsBackendNotificationAdapter → OccBackendNotification` e include `provideLoginEventsTracking()` — integration-libs/cds/src/profiletag/profile-tag.module.ts:L16-L32.
2. `TrackingModule` registra un `APP_INITIALIZER` che chiama `TrackingService.trackEvents()` — integration-libs/cds/src/profiletag/tracking/tracking.module.ts:L10-L20, integration-libs/cds/src/profiletag/tracking/tracking.service.ts:L22-L27. `trackEvents` inoltra **sempre** i cambi di consenso e gli altri eventi solo se l'ultimo consenso è `granted` — integration-libs/cds/src/profiletag/tracking/tracking.service.ts:L28-L48. Il consenso osservato è `cds.consentTemplateId` (default `PROFILE`) — integration-libs/cds/src/profiletag/services/profile-tag-lifecycle.service.ts:L28-L54.
3. `ProfileTagPushEventsService` converte eventi Spartacus (pagine categoria/prodotto/ricerca/home/carrello, `OrderPlacedEvent`, modifiche al carrello, merge) in push event — integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L72-L84 — arricchiti con `segments/actions` dell'ultimo `PersonalizationContext` — integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L98-L113. La personalizzazione è descritta in 33 — Tracking, SmartEdit, Qualtrics; lo schematic CDS ne dichiara la dipendenza — core-libs/schematics/src/shared/lib-configs/integration-libs/cds-schematics-config.ts:L49-L49.
4. Il componente CMS `ProfileTagComponent` (`deferLoading: INSTANT`) non ha UI: sottoscrive `profileTagInjector.track()` con `async` — integration-libs/cds/src/profiletag/cms-components/profile-tag-cms.module.ts:L19-L26, integration-libs/cds/src/profiletag/cms-components/profile-tag.component.ts:L12-L21.
5. `track()` aggiunge il tracker e unisce gli eventi interni di ProfileTag con la notifica di login — integration-libs/cds/src/profiletag/services/profile-tag.injector.service.ts:L24-L45. `addTracker` (solo browser, base site truthy e distinto) inietta `profileTag.javascriptUrl` in `<head>` e scrive la config in `window.Y_TRACKING.q` una sola volta — integration-libs/cds/src/profiletag/services/profiletag-event.service.ts:L111-L119, integration-libs/cds/src/profiletag/services/profiletag-event.service.ts:L154-L211.
6. Gli eventi sono consegnati con `window.Y_TRACKING.eventLayer.push(event)` in try/catch — integration-libs/cds/src/profiletag/services/profiletag-event.service.ts:L121-L129.
7. Il consent reference iniziale si legge da `localStorage['profiletag']`; i successivi arrivano dall'evento window `profiletag_consentReferenceLoaded`; il debug da `profiletag_debugFlagChanged` — integration-

libs/cds/src/profiletag/services/profiletag-event.service.ts:L68-L105, integration-libs/cds/src/profiletag/services/profiletag-event.service.ts:L142-L152, integration-libs/cds/src/profiletag/model/profile-tag.model.ts:L50-L53.

8. `ConsentReferenceInterceptor` aggiunge `X-Consent-Reference` alle sole richieste OCC — integration-libs/cds/src/profiletag/http-interceptors/consent-reference-interceptor.ts:L24-L45; `DebugInterceptor` aggiunge `X-Profile-Tag-Debug` — integration-libs/cds/src/profiletag/http-interceptors/debug-interceptor.ts:L24-L37.
9. **Login.** `provideLoginEventsTracking` crea un `ReplaySubject(1)` esposto con `LOGIN_EVENTS` e, con `provideAppInitializer`, ascolta `ActionsSubject` emettendo un envelope `{action, timestamp}` per ogni `AuthActions.LOGIN` — integration-libs/cds/src/profiletag/providers/login-events.provider.ts:L20-L48. `loginSuccessful()` deduplica per timestamp — integration-libs/cds/src/profiletag/services/profile-tag-lifecycle.service.ts:L28-L54 — e `OccBackendNotification` fa POST `/users/{userId}/loginnotification` — integration-libs/cds/src/profiletag/adapters/occ-backend-notification-adapter.ts:L22-L35. Poiché anche CDC dispatcha `AuthActions.Login()` (§3.4), un login CDC con CDS installato genera la stessa notifica.

3.15 CDS: recent e trending searches

1. `RecentSearchesModule` registra con `provideOutlet` `RecentSearchesComponent` (AFTER su `SearchBoxOutlets.RECENT_SEARCHES`) e `RecentSearchesHeaderComponent` (REPLACE su `RECENT_SEARCHES_HEADER`) — integration-libs/cds/src/recent-searches/recent-searches.module.ts:L34-L45. Per gli outlet vedi 17 — Outlet.
2. `RecentSearchesService` (solo browser) controlla ogni 250 ms fino a 100 volte se esiste `window.Y_TRACKING.recentSearches` — integration-libs/cds/src/recent-searches/recent-searches.service.ts:L17-L55. Il componente filtra e limita a `maxRecentSearches ?? 5` — integration-libs/cds/src/recent-searches/recent-searches.component.ts:L40-L90. Rimozione singola e "Clear" sono dietro il toggle `searchBoxRecentSearchesRemoval`, applicato nel template con `*cxFeature` (header con "Clear" e bottone di rimozione che chiama `removeFromRecentSearch`) — integration-libs/cds/src/recent-searches/recent-searches.component.html:L4-L9, integration-libs/cds/src/recent-searches/recent-searches.component.html:L40-L42, integration-libs/cds/src/recent-searches/recent-searches.component.ts:L124-L129; il toggle decide anche quali eventi inoltrare alla search box — integration-libs/cds/src/recent-searches/recent-searches.component.ts:L105-L108 — il cui default è `false` — core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1041-L1041.
3. `TrendingSearchesModule` registra `TrendingSearchesComponent` AFTER su `TRENDING_SEARCHES` — integration-libs/cds/src/trending-searches/trending-searches.module.ts:L29-L35. `TrendingSearchesService` attende `Y_TRACKING.config.cdsSiteId`, costruisce l'URL `searchIntelligence` e ripete la GET ogni 15 minuti con `shareReplay(1)` — integration-libs/cds/src/trending-searches/trending-searches.service.ts:L29-L89.

3.16 segment-refs

1. Il public API espone solo `SegmentRefsRootModule` — integration-libs/segment-refs/public_api.ts:L10-L10, integration-libs/segment-refs/root/public_api.ts:L7-L7 — che fornisce l'interceptor e la config di default — integration-libs/segment-refs/root/segment-refs-root.module.ts:L12-L20, integration-libs/segment-refs/root/http-interceptors/index.ts:L11-L17.
2. `segmentRefs.httpHeaderName` ha default `'Segmentrefs'` — integration-libs/segment-refs/root/config/default-segment-refs-config.ts:L9-L13.
3. Nel costruttore l'interceptor legge `?segmentrefs=` da `winRef.location.href` e lo salva in localStorage (`segment-refs`), oppure lo rilegge; in browser calcola il nome dell'header in minuscolo — integration-

libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L39-L60.

4. `intercept` aggiunge l'header solo in browser, con header e valore presenti, per URL OCC — integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L69-L86.
5. Lo schematic aggiunge la dipendenza da personalization perché "backend occ api of Segment-refs requires Personalization to be enabled" — core-libs/schematics/src/shared/lib-configs/integration-libs/segment-refs-schematics-config.ts:L36-L39.

3.17 Schematic di installazione e configurazione dei test

`addCdcFeature`, `addCdpFeature` e `addSegmentRefsFeature` eseguono tutte `validateSpartacusInstallation`, `analyzeCrossFeatureDependencies` e poi `chain([analyzeApplication, addFeatures, addPackageJsonDependenciesForLibrary(peerDependencies), finalizeInstallation])` (integration-libs/cdc/schematics/add-cdc/index.ts:L25-L43, integration-libs/cdp/schematics/add-cdp/index.ts:L25-L43, integration-libs/segment-refs/schematics/add-segment-refs/index.ts:L25-L45); la logica specifica (moduli, `importAfter`, config generata) è nelle `*-schematics-config.ts` della sezione 2.4. Gli spec preparano prima la feature da cui dipendono: CDC installa User-Account e User-Profile e verifica che l'opzione `javascriptUrl` finisca nel feature module (integration-libs/cdc/schematics/add-cdc/index_spec.ts:L82-L104); CDP installa prima customer ticketing (integration-libs/cdp/schematics/add-cdp/index_spec.ts:L56-L73); segment-refs installa prima personalization (integration-libs/segment-refs/schematics/add-segment-refs/index_spec.ts:L56-L73).

Le configurazioni Vitest differiscono: `integration-libs/cdc/vitest.config.ts` ha un solo alias (feature toggles testing) e `restoreMocks: true` (integration-libs/cdc/vitest.config.ts:L14-L25); `integration-libs/cds/vitest.config.ts` abbassa le soglie a 80/80/65/80 (integration-libs/cds/vitest.config.ts:L34-L39); `integration-libs/segment-refs/vitest.config.ts` le alza a 90/90/75/90 (integration-libs/segment-refs/vitest.config.ts:L41-L46); `integration-libs/cdp/vitest.config.ts` non dichiara alias (integration-libs/cdp/vitest.config.ts:L13-L25).

---

4. Diagrammi

4.1 Mappa degli override DI

■ **TAVOLA 34.1** diagramma a tutta pagina, in fondo al capitolo

---

5. Estratti di codice reale

5.1 `CdcRootModule`: initializer e override dei guard

integration-libs/cdc/root/cdc-root.module.ts:L26-L69

```ts
export function cdcJsFactory(
  cdcJsService: CdcJsService,
  configInit: ConfigInitializerService
): () => Promise<Config> {
  return () =>
    lastValueFrom(
      configInit.getStable('context', 'cdc').pipe(
        tap(() => {
          cdcJsService.initialize();
        })
      )
    );
}
// ...
@NgModule({
  imports: [CdcConsentManagementModule],
  providers: [
    provideDefaultConfigFactory(defaultCdcComponentsConfig),
    { provide: LogoutGuard, useExisting: CdcLogoutGuard },
    { provide: LoginGuard, useExisting: CdcLoginGuard },
    { provide: LoginAsGuestGuard, useExisting: CdcLoginAsGuestGuard },
    {
      provide: APP_INITIALIZER,
      useFactory: cdcJsFactory,
      deps: [CdcJsService, ConfigInitializerService],
      multi: true,
```

```
    },
    provideDefaultConfig(defaultCdcRoutingConfig),
  ],
})
export class CdcRootModule {}
```

5.2 Caricamento dello script Gigya

integration-libs/cdc/root/service/cdc-js.service.ts:L94-L122

```ts
  loadCdcJavascript(): void {
    // Only load the script on client side (no SSR)
    if (isPlatformBrowser(this.platform)) {
      this.subscription.add(
        combineLatest([
          this.baseSiteService.getActive(),
          this.languageService.getActive(),
        ])
          .pipe(take(1))
          .subscribe(([baseSite, language]) => {
            const scriptForBaseSite =
              this.getJavascriptUrlForCurrentSite(baseSite);
            if (scriptForBaseSite) {
              const javascriptUrl = `${scriptForBaseSite}&lang=${language}`;
              this.scriptLoader.embedScript({
                src: javascriptUrl,
                params: undefined,
                attributes: { type: 'text/javascript' },
                callback: () => {
                  this.registerEventListeners(baseSite);
                  this.getSiteConsentDetails(true).subscribe(); //fetch CDC consents and persist to
local storage
                  this.loaded$.next(true);
                  this.errorLoading$.next(false);
                },
                errorCallback: () => {
                  this.errorLoading$.next(true);
                  this.loaded$.next(false);
                },
              });
```

5.3 `onLogin` e il ponte callback → Observable

integration-libs/cdc/root/service/cdc-js.service.ts:L181-L192

```ts
  protected onLoginEventHandler(baseSite: string, response?: any) {
    if (response && !response?.context?.skipOccAuth) {
      //skip re-authentication during reset email
      this.cdcAuth.loginWithCustomCdcFlow(
        response.UID,
        response.UIDSignature,
        response.signatureTimestamp,
        response.id_token !== undefined ? response.id_token : '',
        baseSite
      );
    }
  }
```

integration-libs/cdc/root/service/cdc-js.service.ts:L734-L755

```ts
  protected invokeAPI(methodName: string, payload: Object): Observable<any> {
    return new Observable<any>((result) => {
      const actualAPI = this.getSdkFunctionFromName(methodName);
      if (typeof actualAPI != 'function') {
        result.error('CDC API name is incorrect');
        return;
      }
      actualAPI({
        ...payload,
        callback: (response: any) => {
          this.zone.run(() => {
            if (response?.status === 'OK') {
              result.next(response);
              result.complete();
            } else {
              result.error(response);
            }
          });
        },
      });
    });
  }
```

5.4 La facade lazy

integration-libs/cdc/root/facade/cdc-auth.facade.ts:L11-L33

```ts
@Injectable({
  providedIn: 'root',
  useFactory: () =>
    facadeFactory({
      facade: CdcAuthFacade,
      feature: CDC_CORE_FEATURE,
```

```
      methods: ['loginWithCustomCdcFlow', 'loginWithToken'],
      async: true,
    }),
})
export abstract class CdcAuthFacade {
  abstract loginWithCustomCdcFlow(
    UID: string,
    UIDSignature: string,
    signatureTimestamp: string,
    idToken: string,
    baseSite: string
  ): void;

  abstract loginWithToken(
    token: Partial<AuthToken> & { expires_in?: number }
  ): void;
}
```

5.5 Token con `grant_type=custom`

integration-libs/cdc/core/auth/services/user-authentication/cdc-user-authentication-token.service.ts:L43-L60

```ts
    const url = this.authConfigService.getTokenEndpoint();
    const params = new HttpParams()
      .set('client_id', this.authConfigService.getClientId())
      .set('client_secret', this.authConfigService.getClientSecret())
      .set('grant_type', 'custom')
      .set('UID', encodeURIComponent(UID))
      .set('UIDSignature', encodeURIComponent(UIDSignature))
      .set('signatureTimestamp', encodeURIComponent(signatureTimestamp))
      .set('id_token', encodeURIComponent(idToken))
      .set('baseSite', encodeURIComponent(baseSite));

    return this.http
      .post<Partial<AuthToken> & { expires_in?: number }>(url, params)
      .pipe(
        catchError((error: any) => {
          throw tryNormalizeHttpError(error, this.logger);
        })
      );
```

5.6 Scrittura del token e login "a mano"

integration-libs/cdc/core/auth/facade/cdc-auth.service.ts:L106-L120

```ts
    stream$.pipe(take(1)).subscribe((canLogin) => {
      if (canLogin) {
        // Code mostly based on auth lib we use and the way it handles token properties
        this.setTokenData(token);

        // OCC specific code
        this.userIdService.setUserId(OCC_USER_ID_CURRENT);

        this.store.dispatch(new AuthActions.Login());

        // Remove any global errors and redirect user on successful login
        this.globalMessageService.remove(GlobalMessageType.MSG_TYPE_ERROR);
        this.authRedirectService.redirect();
      }
    });
```

5.7 Override per sottoclasse: guard

integration-libs/cdc/root/guards/cdc-login.guard.ts:L20-L32

```ts
export class CdcLoginGuard extends LoginGuard {
  constructor(
    protected authService: AuthService,
    protected authConfigService: AuthConfigService,
    protected cmsPageGuard: CmsPageGuard
  ) {
    super(authService, authConfigService, cmsPageGuard);
  }

  protected shouldRenderCMSPage(): Observable<boolean> {
    return of(true); // always load CMS Login Page
  }
}
```

integration-libs/cdc/root/guards/cdc-logout.guard.ts:L43-L55

```ts
  protected logoutFromCdc(): void {
    (this.winRef.nativeWindow as { [key: string]: any })?.[
      'gigya'
    ]?.accounts?.logout();
  }

  /**
   * @override
   * @returns promise to resolve after complete logout
   */
```

```
protected logout(): Promise<any> {
  return Promise.all([super.logout(), Promise.resolve(this.logoutFromCdc())]);
}
```

5.8 Override scoped del login form

integration-libs/cdc/user-account/login-form/cdc-login-form.module.ts:L44-L68

```ts
  provideDefaultConfig(<AuthConfig>{
    authentication: {
      customLoginPage: undefined,
    },
  }),
  provideDefaultConfig(<CmsConfig>{
    cmsComponents: {
      ReturningCustomerLoginComponent: {
        component: LoginFormComponent,
        guards: [NotAuthGuard],
        providers: [
          {
            provide: LoginFormComponentService,
            useClass: CdcLoginFormComponentService,
            deps: [
              AuthService,
              GlobalMessageService,
              WindowRef,
              CdcJsService,
            ],
          },
        ],
      },
    },
  }),
```

E il meccanismo che lo rende possibile, core-libs/storefront/cms-structure/page/component/services/cms-injector.service.ts:L28-L50:

```ts
public getInjector(
  type: string,
  uid: string,
  parentInjector?: Injector
): Injector {
  const configProviders =
    this.cmsComponentsService.getMapping(type)?.providers ?? [];
  return Injector.create({
    providers: [
      {
        provide: CmsComponentData,
```

```
        useFactory: (dataProvider: ComponentDataProvider) => ({
          uid,
          data$: dataProvider.get(uid, type),
        }),
        deps: [ComponentDataProvider],
      },
      provideLcpPresenceForCmsComponent(),
      ...configProviders,
    ],
    parent: parentInjector ?? this.injector,
  });
}
```

5.9 Override con riaccodamento dei provider originali

integration-libs/cdc/organization/administration/cdc-administration.module.ts:L23-L43

```ts
@NgModule({
  providers: [
    //to override UserListService in ListComponent
    provideDefaultConfig(<CmsConfig>{
      cmsComponents: {
        ManageUsersListComponent: {
          providers: [
            {
              provide: UserListService,
              useExisting: CdcUserListService,
            },
            { provide: B2BUserService, useClass: CdcB2BUserService },
            userCmsConfig.cmsComponents?.ManageUsersListComponent?.providers ||
              [],
          ],
        },
      },
    }),
    //to override B2BUserService in UserDetailsComponent, UnitUserListComponent
    { provide: B2BUserService, useClass: CdcB2BUserService },
    //to override B2BUserService in UnitUserRolesCellComponent
```

5.10 Adapter consensi ibrido CDC/OCC

integration-libs/cdc/root/consent-management/cdc-user-consent.adapter.ts:L35-L65

```ts
  giveConsent(
    userId: string,
    consentTemplateId: string,
    consentTemplateVersion: number
```

```
  ): Observable<ConsentTemplate> {
    if (!this.cdcConsentsStorage.checkIfConsentExists(consentTemplateId)) {
      return super.giveConsent(
        userId,
        consentTemplateId,
        consentTemplateVersion
      );
    } else {
      return this.cdcUserConsentService
        .updateCdcUserPreferences([
          { id: consentTemplateId, isConsentGranted: true },
        ])
        .pipe(
          catchError((error: any) => throwError(error)),
          switchMap((result) => {
            if (result?.errorCode === 0) {
              return super.giveConsent(
                userId,
                consentTemplateId,
                consentTemplateVersion
              );
            }
            return EMPTY;
          })
        );
    }
  }
```

5.11 CDP: tre righe di override

integration-libs/cdp/customer-ticketing/cdp-customer-ticketing.module.ts:L17-L35

```ts
@NgModule({
  imports: [],
  providers: [
    {
      provide: CustomerTicketingCloseComponentService,
      useClass: CdpCustomerTicketingCloseComponentService,
    },
    {
      provide: CustomerTicketingReopenComponentService,
      useClass: CdpCustomerTicketingReopenComponentService,
    },
    {
      provide: CustomerTicketingMessagesComponentService,
      useClass: CdpCustomerTicketingMessagesComponentService,
    },
  ],
```

```
  declarations: [],
})
export class CdpCustomerTicketingModule {}
```

5.12 CDS: `forRoot` e validazione

integration-libs/cds/src/cds.module.ts:L26-L47

```ts
@NgModule({
  imports: [
    ProfileTagModule,
    TrackingModule,
    MerchandisingModule,
    RecentSearchesModule,
    TrendingSearchesModule,
  ],
})
export class CdsModule {
  static forRoot(config?: CdsConfig): ModuleWithProviders<CdsModule> {
    return {
      ngModule: CdsModule,
      providers: [
        provideDefaultConfigFactory(defaultCdsConfigFactory),
        provideDefaultConfig(config),
        provideConfigValidator(cdsConfigValidator),
        ProfileTagPushEventsService,
      ],
    };
  }
}
```

5.13 CDS: strategy adapter (SSR-safe)

integration-libs/cds/src/merchandising/adapters/strategy/cds-merchandising-strategy.adapter.ts:L30-L61

```ts
  loadProductsForStrategy(
    strategyId: string,
    strategyRequest: StrategyRequest = {}
  ): Observable<StrategyProducts> {
    if (!this.windowRef.isBrowser()) {
      return of({ products: [] });
    }

    let headers: HttpHeaders = new HttpHeaders();
    if (strategyRequest.headers && strategyRequest.headers.consentReference) {
      headers = headers.set(
```

```
        'consent-reference',
        strategyRequest.headers.consentReference
      );
    }
    return this.baseSiteService.getActive().pipe(
      take(1),
      switchMap((baseSite) =>
        this.http.get(
          this.cdsEndpointsService.getUrl(
            STRATEGY_PRODUCTS_ENDPOINT_KEY,
            {
              baseSite,
              strategyId,
            },
            strategyRequest.queryParams
          ),
          { headers }
        )
      )
    );
  }
```

5.14 CDS: filtro per consenso

integration-libs/cds/src/profiletag/tracking/tracking.service.ts:L28-L48

```ts
  trackEvents(): void {
    this.profileTagPushEventsService
      .getPushEvents()
      .pipe(
        withLatestFrom(
          this.profileTagLifecycleService.consentChanged().pipe(
            tap((event) => {
              // always notify of consent changes
              this.profileTagEventTracker.notifyProfileTagOfEventOccurrence(
                event
              );
            })
          )
        ),
        filter(([_event, consentChanged]) => consentChanged.data.granted), //don't notify other events
until consent is granted
        tap(([event]) => {
          this.profileTagEventTracker.notifyProfileTagOfEventOccurrence(event);
        })
      )
      .subscribe();
  }
```

5.15 CDS: login events con `provideAppInitializer`

integration-libs/cds/src/profiletag/providers/login-events.provider.ts:L20-L48

```ts
export function provideLoginEventsTracking() {
  const loginEvents$ = new ReplaySubject<LoginEventEnvelope>(1);

  return [
    {
      provide: LOGIN_EVENTS,
      useValue: loginEvents$.asObservable(),
    },
    provideAppInitializer(() => {
      const actionsSubject = inject(ActionsSubject);
      actionsSubject
        .pipe(
          filter(
            (action): action is AuthActions.Login =>
              action.type === AuthActions.LOGIN
          ),
          tap((action) => {
            const envelope: LoginEventEnvelope = {
              action,
              timestamp: Date.now(),
            };
            loginEvents$.next(envelope);
          }),
          takeUntilDestroyed()
        )
        .subscribe();
    }),
  ];
}
```

5.16 segment-refs: interceptor completo

integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L39-L60

```ts
  protected initialize() {
    const url = this.winRef.location.href ?? '';
    const queryParams = new URLSearchParams(url.substring(url.indexOf('?')));
    this.segmentRefs = queryParams.get(this.SEGMENT_REFS_QUERY_PARAM);
    if (this.segmentRefs) {
      this.winRef.localStorage?.setItem(
        this.SEGMENT_REFS_KEY,
        this.segmentRefs
      );
    } else {
      this.segmentRefs = this.winRef.localStorage?.getItem(
```

```
        this.SEGMENT_REFS_KEY
      );
    }
    if (this.winRef.isBrowser()) {
      if (!this.config.segmentRefs?.httpHeaderName && isDevMode()) {
        this.logger.warn(`There is no httpHeaderName configured in Segment`);
      }
      this.requestHeader =
        this.config.segmentRefs?.httpHeaderName?.toLowerCase?.();
    }
  }
```

integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L69-L86

TS

```
  intercept(
    request: HttpRequest<any>,
    next: HttpHandler
  ): Observable<HttpEvent<any>> {
    if (
      this.winRef.isBrowser() &&
      this.requestHeader &&
      this.segmentRefs &&
      request.url.includes(this.occEndpoints.getBaseUrl())
    ) {
      request = request.clone({
        setHeaders: {
          [this.requestHeader]: this.segmentRefs,
        },
      });
    }
    return next.handle(request);
  }
```

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
localStorage `profiletag`	JSON `{cr: {...}}`	`{"cr":{}}`	scritto dallo script ProfileTag (esterno)	`integration-libs/cds/src/profiletag/services/profiletag-event.service.ts:L68-L105`

Esempio minimo (forma derivata dai default e dallo schematic, `core-libs/schematics/src/shared/lib-configs/integration-libs/cdc-schematics-config.ts:L161-L171`):

```ts
provideConfig(<CdcConfig>{
  cdc: [
    {
      baseSite: 'electronics-cdc',
      javascriptUrl: 'https://cdns.<region>.gigya.com/JS/gigya.js?apikey=<KEY>',
      sessionExpiration: 3600,
    },
  ],
});
```

DA VERIFICARE: l'URL di esempio è illustrativo (il dominio Gigya non è nel repo); il codice richiede solo che contenga `?apikey=` e accetti l'aggiunta di `&lang=` (`integration-libs/cdc/root/service/cdc-js.service.ts:L104-L107`, `integration-libs/cdc/root/service/cdc-js.service.ts:L762-L782`).

---

7. Commenti e note notevoli dal sorgente

- "@override CDC version of logout guard. In addition to token revocation we invoke logout method from CDC JS lib." — `integration-libs/cdc/root/guards/cdc-logout.guard.ts:L18-L22`. Il parametro `cms` del costruttore è `@deprecated since 2611`, usato solo nel percorso legacy quando `useConfigurableLogoutRedirect` è disabilitato — `integration-libs/cdc/root/guards/cdc-logout.guard.ts:L29-L30`.
- "// by default core is bundled together with components" — `integration-libs/cdc/root/cdc-root.module.ts:L46-L46`: spiega l'alias `cdcCore → cdc`; un'app può separare i chunk ridefinendo `featureModules.cdcCore`.
- "//overriding to avoid same path in different routes" — `integration-libs/cdc/root/config/default-cdc-routing-config.ts:L31-L31`.
- "// Only load the script on client side (no SSR)" — `integration-libs/cdc/root/service/cdc-js.service.ts:L95-L95`.
- Il workaround della verifica password con `skipOccAuth` è documentato estesamente — `integration-libs/cdc/root/service/cdc-js.service.ts:L635-L640`; "//skip re-authentication during reset email" — `integration-libs/cdc/root/service/cdc-js.service.ts:L183-L183`.
- "// Code mostly based on auth lib we use and the way it handles token properties" — `integration-libs/cdc/core/auth/facade/cdc-auth.service.ts:L108-L108`: CDC replica il formato di storage della libreria OAuth invece di passare da essa.
- "// Intentional empty method , so csrf token is not initialized in case of CDC" — `integration-libs/cdc/user-account/login-form/cdc-login-form-component.service.ts:L69-L69`.
- `selector: 'cx-anonymous-consent-dialog', //reusing existing selector` — `integration-libs/cdc/user-account/login-form/reconsent/cdc-reconsent.component.ts:L38-L39`.

- I commenti di `CdcAdministrationModule` dicono esattamente quale componente ogni override deve raggiungere (`ListComponent`, `UserDetailsComponent`, `UnitUserListComponent`, `UnitUserRolesCellComponent`) — integration-libs/cdc/organization/administration/cdc-administration.module.ts:L25-L25, integration-libs/cdc/organization/administration/cdc-administration.module.ts:L41-L43.
- `// TODO:#cds - check the class name and the name property` su `BrandPageVisitedEvent` — integration-libs/cds/src/profiletag/model/profile-tag.model.ts:L111-L111.
- `startWith(<PageEvent>null), // https://github.com/ReactiveX/rxjs/issues/4772` — integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L137-L137.
- "Uses ReplaySubject to ensure no login events are missed. Provides timestamp to deduplicate login events." — integration-libs/cds/src/profiletag/providers/login-events.provider.ts:L15-L19.
- "If the endpoint to get the url for already has the configured base url appended, do not try and append it again" — integration-libs/cds/src/services/cds-endpoints.service.ts:L68-L71.
- Schematic segment-refs: "Through Spartacus Segment-refs code doesnot have a dependency on Personalization, backend occ api of Segment-refs requires Personalization to be enabled" — core-libs/schematics/src/shared/lib-configs/integration-libs/segment-refs-schematics-config.ts:L36-L39.

8. Extension point

EXTENSION POINT	COME USARLO	RIFERIMENTO	RICETTA
`CdcConfig`	config per base site (`cdc[]`)	integration-libs/cdc/root/config/cdc-config.ts:L10-L24	50 — Ricette config/DI
`CdcJsService` (metodi `protected`: `onLoginEventHandler`, `invokeAPI`, `handleLoginError`…)	sottoclasse + `{ provide: CdcJsService, useClass: MyCdcJsService }` nel root	integration-libs/cdc/root/service/cdc-js.service.ts:L43-L52, integration-libs/cdc/root/service/cdc-js.service.ts:L181-L192	50
`CdcLoginGuard`, `CdcLogoutGuard`, `CdcLoginAsGuestGuard`	ulteriore sottoclasse e override del token core (`LoginGuard`…)	integration-libs/cdc/root/cdc-root.module.ts:L57-L59	50, 51 — Ricette CMS/route
`CdcAuthFacade` / feature `cdcCore`	separare il chunk core ridefinendo `featureModules.cdcCore`	integration-libs/cdc/root/facade/cdc-auth.facade.ts:L11-L33, integration-libs/cdc/root/cdc-root.module.ts:L40-L51	53 — Ricette feature lazy
`CdcLoadUserTokenFailEvent`, `CdcReConsentEvent`	`EventService.get(...)`	integration-libs/cdc/root/events/cdc-event.ts:L13-L31	50
`CDC_PREFERENCE_SERIALIZER`	aggiungere un converter multi (attenzione all'ordine, §9)	integration-libs/cdc/root/consent-management/converters/converter.ts:L11-L13	52 — Ricette OCC/converter
`cmsComponents.<Tipo>.providers`	override scoped di component service (schema CDC)	core-libs/storefront/cms-structure/page/component/services/cms-injector.service.ts:L28-L50	51
`MerchandisingStrategyAdapter`	sostituire la sorgente delle strategie	integration-libs/cds/src/merchandising/connectors/strategy/merchandising-strategy.adapter.ts:L11-L21	52
`CdsBackendNotificationAdapter`	sostituire la notifica di login	integration-libs/cds/src/profiletag/profile-tag.module.ts:L16-L32	52

EXTENSION POINT	COME USARLO	RIFERIMENTO	RICETTA
`ProfileTagPushEventsService.addPushEvent(event$)`	aggiungere eventi custom a ProfileTag (prima di `trackEvents`, §9)	`integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L121-L123`	50
`CdsModule.forRoot(config?)` / `CdsConfig`	config CDS (anche via factory, come la demo app)	`integration-libs/cds/src/cds.module.ts:L26-L47`, `projects/storefrontapp/src/app/spartacus/features/cds/cds-feature.module.ts:L70-L82`	50
Outlet `SearchBoxOutlets.RECENT_SEARCHES`, `RECENT_SEARCHES_HEADER`, `TRENDING_SEARCHES`	`provideOutlet` con componenti propri	`integration-libs/cds/src/recent-searches/recent-searches.module.ts:L34-L45`, `integration-libs/cds/src/trending-searches/trending-searches.module.ts:L29-L35`	51
`CdpCustomerTicketingModule`	esempio di override di component service in feature lazy	`integration-libs/cdp/customer-ticketing/cdp-customer-ticketing.module.ts:L17-L35`	53
`segmentRefs.httpHeaderName`	rinominare l'header	`integration-libs/segment-refs/root/config/default-segment-refs-config.ts:L9-L13`	50

Cosa **non** è API pubblica (e quindi a rischio negli upgrade, vedi 54 — API pubblica vs interna): lo store CDC (`integration-libs/cdc/core/public_api.ts:L7-L10`), `CdsEndpointsService` e `recent-searches` (`integration-libs/cds/public_api.ts:L10-L15`), il token `LOGIN_EVENTS` (`integration-libs/cds/src/profiletag/tokens/login-events.token.ts:L20-L22`), `SegmentRefsConfig` e `OccSegmentRefsInterceptor` (`integration-libs/segment-refs/root/public_api.ts:L7-L7`), e i moduli/servizi update-email/password/profile di `@spartacus/cdc/user-profile` (`integration-libs/cdc/user-profile/public_api.ts:L7-L9`).

---

9. Trappole, casi limite, comportamenti controintuitivi

1. **Logout Gigya mai eseguito da** `logoutUser()`. `invokeAPI` ritorna un Observable cold e `logoutUser` non si sottoscrive: `accounts.logout` non parte da questo percorso (il logout via route usa invece `CdcLogoutGuard`, che chiama direttamente `gigya.accounts.logout()`) — `integration-libs/cdc/root/service/cdc-js.service.ts:L850-L853`, `integration-libs/cdc/root/service/cdc-js.service.ts:L734-L755`, `integration-libs/cdc/root/guards/cdc-logout.guard.ts:L43-L55`.
2. **Update email senza logout.** In `updateUserEmailWithoutScreenSet` l'Observable con `tap({complete: logoutUser})` non viene sottoscritto: l'update Commerce parte comunque (facade eager) ma il logout no — `integration-libs/cdc/root/service/cdc-js.service.ts:L651-L661`, `core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L70-L82`.
3. **Messaggio di reset password irraggiungibile.** `handleResetPassResponse` gestisce anche `status === 'OK'`, ma è agganciato solo al ramo `error` del `tap` — `integration-libs/cdc/root/service/cdc-js.service.ts:L466-L494`. Il messaggio di successo arriva dal component service (`onSuccess()` se `status === 'OK'`) — `integration-libs/cdc/user-profile/forgot-password/cdc-forgot-password-component.service.ts:L44-L79`.
4. **Letture "sincrone" di stream.** `getCurrentBaseSite`, `getCurrentBaseSiteChannel`, `getUserID` sottoscrivono e ritornano subito: se il valore non è già emesso ottieni `''`/`undefined` (es. `ignoreInterruptions` resta `false`); `getUserID` non fa unsubscribe — `integration-libs/cdc/root/service/cdc-js.service.ts:L436-L453`, `integration-libs/cdc/root/consent-management/services/cdc-user-consent.service.ts:L71-L77`.

5. **Base site non configurato = attesa infinita.** Senza voce `cdc[]` per il sito (o in SSR) lo script non viene caricato e `loaded$` non emette mai: chi attende `didLoad()` resta bloccato (spinner del login) — integration-libs/cdc/root/service/cdc-js.service.ts:L94-L106, integration-libs/cdc/user-account/login-form/cdc-login-form-component.service.ts:L34-L66.
6. `apikey` **obbligatorio nell'URL.** `getSiteConsentDetails` estrae `apikey` dalla query di `javascriptUrl`; se manca invia `apiKey: null` — integration-libs/cdc/root/service/cdc-js.service.ts:L762-L782.
7. **Nomi API errati risolti "a metà".** `getSdkFunctionFromName` salta i segmenti mancanti; il nome sbagliato è scartato solo dal controllo `typeof != 'function'` — integration-libs/cdc/root/service/cdc-js.service.ts:L713-L726, integration-libs/cdc/root/service/cdc-js.service.ts:L734-L740.
8. **Side effect nel template.** `GigyaRaasComponent` chiama `displayScreenSet` da un'interpolazione `{{ }}`, protetto solo dal flag `renderScreenSet` — integration-libs/cdc/components/gigya-raas/gigya-raas.component.html:L8-L8, integration-libs/cdc/components/gigya-raas/gigya-raas.component.ts:L27-L59. Vedi 04 — Change detection.
9. `GigyaRaasGuard` **nega l'accesso se non riesce a leggere i dati del componente.** È un guard di componente CMS: `CmsPageGuardService` esegue solo i guard dei tipi di componente presenti nella pagina, quindi gira solo dove c'è `GigyaRaasComponent` — core-libs/storefront/cms-structure/guards/cms-page-guard.service.ts:L71-L80, core-libs/storefront/cms-structure/services/cms-guards.service.ts:L41-L41. Lì restituisce `false` se la lookup dei componenti o dei loro dati fallisce o torna vuota (`!componentData.length`, `catchError → of([])`/`of(false)`, dati `{}`) — integration-libs/cdc/components/gigya-raas/gigya-raas.guard.ts:L41-L43, integration-libs/cdc/components/gigya-raas/gigya-raas.guard.ts:L66-L68, integration-libs/cdc/components/gigya-raas/gigya-raas.guard.ts:L95-L95.
10. **Gli array di config si sostituiscono, non si uniscono.** `deepMerge` assegna gli array così come sono: l'override CDC di `ReturningCustomerLoginComponent` elimina `CustomLoginGuard`, e `CdcAdministrationModule` deve riaccodare a mano i provider originali di `ManageUsersListComponent`. Chi aggiunge un proprio override sopra CDC deve fare lo stesso, e l'esito dipende dall'ordine dei chunk di default config (gli schematic usano `importAfter`) — core-libs/core/src/config/utils/deep-merge.ts:L36-L45, feature-libs/user/account/components/login-form/login-form.module.ts:L52-L59, integration-libs/cdc/organization/administration/cdc-administration.module.ts:L23-L62. Vedi 11 — Configurazione.
11. **Override "globali" che non sono globali.** `CdcAdministrationModule`, `CDCB2BRegisterModule` e `CdpCustomerTicketingModule` forniscono provider di NgModule: importati nel wrapper lazy valgono solo nell'injector della feature, e solo se importati **dopo** il modulo originale — projects/storefrontapp/src/app/spartacus/features/organization/administration-wrapper.module.ts:L12-L20, projects/storefrontapp/src/app/spartacus/features/customer-ticketing/customer-ticketing-wrapper.module.ts:L13-L22. Importarli nel root non basterebbe se il modulo lazy rifornisce lo stesso token (il provider più vicino vince): `DA VERIFICARE` caso per caso nei moduli feature, perché dipende da dove la feature fornisce il servizio base (per customer ticketing è nel modulo componente, feature-libs/customer-ticketing/components/details/customer-ticketing-close/customer-ticketing-close.module.ts:L44-L45).
12. **Root "pesante".** `CdcRootModule` (eager) importa `LoginAsGuestGuard` da `@spartacus/user/account/components`, e `CdcJsService` dipende da `@spartacus/user/profile/root` e `@spartacus/organization/user-registration/root`: questi entry point finiscono nel bundle iniziale — integration-libs/cdc/root/cdc-root.module.ts:L24-L24, integration-libs/cdc/root/service/cdc-js.service.ts:L26-L27.
13. **Due provider di** `CdcAuthService`**.** È fornito sia da `CdcCoreModule` (`facadeProviders`) sia da `CdcStoreModule`; stessi injector lazy → un'istanza, ma l'effect inietta la classe concreta e non la facade: un override di `CdcAuthFacade` non intercetta `loginWithToken` chiamato dall'effect — integration-libs/cdc/core/cdc-core.module.ts:L13-L17, integration-libs/cdc/core/store/cdc-store.module.ts:L14-L18, integration-libs/cdc/core/store/effects/cdc-user-token.effect.ts:L61-L65.

14. **Effect indirizzi che può terminare.** In `CdcUserAddressesEffects` il `tap({error})` sta dopo `mergeMap` sul flusso principale: un errore CDC si propaga nello stream dell'effect — integration-libs/cdc/core/store/effects/cdc-user-addresses.effect.ts:L27-L61. NgRx lo ri-sottoscrive (default `useEffectsErrorHandler: true`; Spartacus non ridefinisce `EFFECTS_ERROR_HANDLER`) fino a 10 volte, passando ogni errore all'`ErrorHandler`; dopo, un ulteriore errore lo termina definitivamente — deps:ngrx-effects-21.0.1/package/fesm2022/ngrx-effects.mjs:L9-L13, deps:ngrx-effects-21.0.1/package/fesm2022/ngrx-effects.mjs:L174-L185, deps:ngrx-effects-21.0.1/package/fesm2022/ngrx-effects.mjs:L262-L262.
15. **Errore di update email sempre "password non valida"** — integration-libs/cdc/user-profile/update-email/cdc-update-email-component.service.ts:L38-L64.
16. **Serializer multi che ignora il target.** `ConverterService` passa a ogni converter il `target` del precedente (`reduce`), ma `CdcPreferenceSerializer.convert(source, _target)` ignora `_target` e riparte da `{}`: un serializer custom registrato **prima** di quello CDC viene di fatto scartato; uno registrato **dopo** riceve il risultato CDC — core-libs/core/src/util/converter.service.ts:L130-L137, integration-libs/cdc/root/consent-management/converters/cdc-preference.serializer.ts:L18-L38.
17. `ConsentManagementComponentService` **fornito due volte.** Sia da `ConsentManagementModule` (storefront) sia da `CdcConsentManagementModule`: se il modulo storefront è nell'injector più vicino al componente, il suo provider vince — core-libs/storefront/cms-components/myaccount/consent-management/consent-management.module.ts:L47-L48, integration-libs/cdc/root/consent-management/cdc-consent.module.ts:L16-L31. `DA VERIFICARE` per app non generate dagli schematic (dipende da dove è importato `ConsentManagementModule`).
18. **Scope** `'cdc'` **fantasma.** Nessun initializer nel repo dichiara lo scope `cdc`, e `'cdc'` non si sovrappone a `'context'`: l'attesa di `cdcJsFactory` dipende dal solo scope `context`. Se un'app carica la config `cdc[]` da remoto con un `ConfigInitializer`, deve dichiarare `scopes: ['cdc']` perché l'initializer CDC la aspetti — integration-libs/cdc/root/cdc-root.module.ts:L26-L38, core-libs/core/src/site-context/config/config-loader/site-context-config-initializer.ts:L26-L26, core-libs/core/src/config/config-initializer/config-initializer.service.ts:L117-L122.
19. **CDS senza** `endpoints` **lancia** `TypeError`**.** `getUrl` accede a `this.cdsConfig?.cds?.endpoints[endpoint]` senza optional chaining su `endpoints`, e i default non lo definiscono; il validator avvisa solo in dev mode — integration-libs/cds/src/services/cds-endpoints.service.ts:L18-L25, integration-libs/cds/src/config/default-cds-config.ts:L9-L23, core-libs/core/src/config/config-validator/config-validator.module.ts:L29-L33.
20. **Messaggio del validator fuorviante.** Se manca `profileTag.javascriptUrl` il messaggio parla di `configUrl` (copy-paste) — integration-libs/cds/src/config/cds-config-validator.ts:L20-L25.
21. `getConsentReference()` **può essere** `null`**.** Senza `nativeWindow` ritorna `null`, ma lo user context di merchandising chiama `.pipe` senza controllo quando il consenso è dato — integration-libs/cds/src/profiletag/services/profiletag-event.service.ts:L92-L105, integration-libs/cds/src/merchandising/facade/cds-merchandising-user-context.service.ts:L40-L122.
22. **Prodotti senza categorie.** `categoriesToIds(categories)` non gestisce `undefined` — integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L203-L209, integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L406-L408.
23. `addPushEvent` **troppo tardi non ha effetto.** `getPushEvents()` cattura `pushEvents$` al momento della chiamata, cioè nell'`APP_INITIALIZER` di `TrackingModule`: eventi aggiunti dopo non vengono tracciati — integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L98-L123, integration-libs/cds/src/profiletag/tracking/tracking.service.ts:L28-L31.
24. `ProfileTagPushEventsService` **doppio provider.** È `providedIn: 'root'` e fornito anche da `CdsModule.forRoot` — integration-libs/cds/src/profiletag/services/profile-tag-push-events.service.ts:L68-L70, integration-libs/cds/src/cds.module.ts:L26-L47.

25. **Interceptor per sottostringa.** I due interceptor CDS e quello segment-refs agiscono su ogni URL che *contiene* `occEndpoints.getBaseUrl()`; `DebugInterceptor` aggiunge l'header anche con valore `false` — integration-libs/cds/src/profiletag/http-interceptors/consent-reference-interceptor.ts:L24-L45, integration-libs/cds/src/profiletag/http-interceptors/debug-interceptor.ts:L24-L37, integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L69-L86.
26. **Config ProfileTag scritta una volta sola.** `exposeConfig` scrive in `Y_TRACKING.q` solo se vuoto: un cambio di base site non aggiorna la config — integration-libs/cds/src/profiletag/services/profiletag-event.service.ts:L154-L211.
27. **Polling su oggetti globali.** Recent/trending searches controllano ogni 250 ms fino a 100 volte (~25 s) e trending ripete la GET ogni 15 minuti finché il servizio root vive — integration-libs/cds/src/recent-searches/recent-searches.service.ts:L17-L55, integration-libs/cds/src/trending-searches/trending-searches.service.ts:L29-L89.
28. **Refuso nell'API pubblica:** `getMerchandisingCaourselViewportThreshold` — integration-libs/cds/src/merchandising/cms-components/merchandising-carousel/merchandising-carousel.component.service.ts:L44-L53.
29. `cds.baseSite` **non è letto dalla libreria**, solo dalla factory della demo app — integration-libs/cds/src/config/cds-config.ts:L13-L31, projects/storefrontapp/src/app/spartacus/features/cds/cds-feature.module.ts:L70-L82.
30. **segment-refs in SSR.** L'interceptor legge `winRef.location.href` nel costruttore; in SSR senza `SERVER_REQUEST_URL` `WindowRef.location` lancia un errore — integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L39-L42, core-libs/core/src/window/window-ref.ts:L70-L82. Inoltre `SegmentRefsConfig` non è esportato: la config va scritta senza tipo — integration-libs/segment-refs/root/public_api.ts:L7-L7.
31. **Doppio sistema di login con ASM.** `loginWithToken` rifiuta il login cliente se un agente CS è già loggato — integration-libs/cdc/core/auth/facade/cdc-auth.service.ts:L68-L104; vedi 29 — ASM.
32. **Consensi senza lista CDC persistita → `TypeError`.** Se `cdc-consents-list` non è mai stata scritta (script Gigya non caricato, trappola 5, o callback di `getSiteConsentDetails(true)` non ancora arrivato), `readStateFromStorage` ritorna `undefined` e `checkIfConsentExists` chiama `undefined.forEach`: `giveConsent` e `withdrawConsent` lanciano `TypeError` senza chiamare né OCC né CDC — integration-libs/cdc/root/consent-management/services/cdc-consents-local-storage.service.ts:L57-L76, core-libs/core/src/state/utils/browser-storage.ts:L65-L68, integration-libs/cdc/root/consent-management/cdc-user-consent.adapter.ts:L67-L75.
33. **Coverage non abilitata di default in cdc, cdp, cds.** Il blocco `coverage` di queste tre librerie non contiene `enabled: true`, presente invece in segment-refs e nelle feature lib (es. feature-libs/product/vitest.config.ts:L33-L34), e ha il solo reporter `lcov` — integration-libs/cdc/vitest.config.ts:L30-L39, integration-libs/cdp/vitest.config.ts:L26-L35, integration-libs/cds/vitest.config.ts:L24-L33. `DA VERIFICARE`: che le soglie vengano applicate solo con `--coverage` dipende dal default di Vitest, non verificabile senza `node_modules`.
34. **Exclude verso un file inesistente.** cdc, cdp e segment-refs escludono dalla coverage `../../testing/setup-test.ts`, ma il setup effettivo è `testing/setup-vitest.ts` (unico file di setup presente in `testing/` insieme a `testing/patch-object-define-property.ts`) — integration-libs/cdc/vitest.config.ts:L25-L25, integration-libs/cdc/vitest.config.ts:L38-L38, integration-libs/cdp/vitest.config.ts:L34-L34, integration-libs/segment-refs/vitest.config.ts:L38-L38.

10. Come fare debug

- **Lo script Gigya è caricato?** In DevTools verificare che esista `window.gigya` e uno `<script>` con l'URL `javascriptUrl&lang=...` — integration-libs/cdc/root/service/cdc-js.service.ts:L104-L122. Se manca: controllare che `cdc[].baseSite` coincida con il base site attivo — integration-libs/cdc/root/service/cdc-js.service.ts:L141-L149 — e che si sia in browser (non SSR) — integration-libs/cdc/root/service/cdc-js.service.ts:L94-L96.
- `didLoad()` **non emette.** Sottoscrivere `CdcJsService.didLoad()` e `didScriptFailToLoad()` (es. da un componente di debug): `errorLoading$ = true` indica errore di rete, nessuna emissione indica che lo script non è mai stato richiesto (trappola 5).
- **Login CDC non produce sessione Commerce.** Nel tab Network cercare la POST al token endpoint con `grant_type=custom` — integration-libs/cdc/core/auth/services/user-authentication/cdc-user-authentication-token.service.ts:L43-L60. Assente: la facade non ha caricato il chunk (verificare `featureModules.cdc.module`) — projects/storefrontapp/src/app/spartacus/features/cdc/cdc-feature.module.ts:L17-L40. Presente con errore: compare `httpHandlers.badGateway` e viene emesso `CdcLoadUserTokenFailEvent` — integration-libs/cdc/core/store/effects/cdc-user-token.effect.ts:L44-L55. Con NgRx DevTools osservare `[Auth] Load CDC User Token` seguita (in caso di successo) da `AuthActions.Login` — integration-libs/cdc/core/store/actions/cdc-user-token.action.ts:L10-L41.
- **Successo token ma nessun login.** Verificare se c'è un agente ASM loggato (`asm.auth.agentLoggedInError`) — integration-libs/cdc/core/auth/facade/cdc-auth.service.ts:L68-L104.
- **Quale servizio è attivo?** Per gli override scoped, ispezionare l'injector del componente CMS (Angular DevTools → Injector tree): `LoginFormComponentService` deve risolvere a `CdcLoginFormComponentService` — core-libs/storefront/cms-structure/page/component/services/cms-injector.service.ts:L28-L50. Per gli override nelle feature lazy, verificare l'ordine degli import nel wrapper — projects/storefrontapp/src/app/spartacus/features/user/user-account-wrapper.module.ts:L13-L22.
- **Consensi.** Leggere in localStorage la chiave `spartacus⚿⚿cdc-consents-list` (prefisso `spartacus⚿`, contesto vuoto, separatore ⚿ — core-libs/core/src/state/services/state-persistence.service.ts:L124-L131): se un consenso manca lì, l'adapter usa solo OCC; se la chiave manca del tutto, `giveConsent`/`withdrawConsent` lanciano `TypeError` (§9) — integration-libs/cdc/root/consent-management/cdc-user-consent.adapter.ts:L35-L65, integration-libs/cdc/root/consent-management/services/cdc-consents-local-storage.service.ts:L15-L51.
- **CDS, config.** In dev mode la console mostra i warning del validator (`Please configure cds.tenant...`) — integration-libs/cds/src/config/cds-config-validator.ts:L9-L44. Un `TypeError` in `getUrl` indica `cds.endpoints` mancante (trappola 19).
- **CDS, eventi.** Ispezionare `window.Y_TRACKING.eventLayer` e `window.Y_TRACKING.q` — integration-libs/cds/src/profiletag/services/profiletag-event.service.ts:L121-L129, integration-libs/cds/src/profiletag/services/profiletag-event.service.ts:L154-L211. Se compaiono solo eventi `ConsentChanged`, il consenso `PROFILE` non è dato (filtro di `trackEvents`) — integration-libs/cds/src/profiletag/tracking/tracking.service.ts:L28-L48.
- **CDS, header.** Sulle chiamate OCC controllare `X-Consent-Reference` e `X-Profile-Tag-Debug` — integration-libs/cds/src/profiletag/http-interceptors/consent-reference-interceptor.ts:L24-L45, integration-libs/cds/src/profiletag/http-interceptors/debug-interceptor.ts:L24-L37; il carousel in SSR è sempre vuoto per design — integration-libs/cds/src/merchandising/adapters/strategy/cds-merchandising-strategy.adapter.ts:L30-L36.
- **segment-refs.** Aprire una pagina con `?segmentrefs=XYZ`, verificare la chiave `segment-refs` in localStorage e l'header `segmentrefs` (minuscolo) sulle chiamate OCC — integration-libs/segment-refs/root/http-

interceptors/occ-segment-refs.interceptor.ts:L39-L60, integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L69-L86.

- **CDP.** Se i pulsanti di chiusura/riapertura sono ancora visibili, `CdpCustomerTicketingModule` non è nell'injector della feature o è importato prima di `CustomerTicketingModule` — core-libs/schematics/src/shared/lib-configs/integration-libs/cdp-schematics-config.ts:L28-L40.

Per gli interceptor HTTP in generale vedi 06 — HttpClient e interceptor.

---

11. Domande di autoverifica

1. **Perché un login fatto con il form Spartacus in un'app CDC non chiama mai** `AuthService.loginWithCredentials`**?** Perché `CDCLoginFormModule` sostituisce, nell'injector del componente `ReturningCustomerLoginComponent`, `LoginFormComponentService` con `CdcLoginFormComponentService`, il cui `login()` usa `loginUserWithoutScreenSet` (Gigya `accounts.login`); la sessione Commerce nasce poi dall'evento `onLogin`. — integration-libs/cdc/user-account/login-form/cdc-login-form.module.ts:L49-L68, integration-libs/cdc/user-account/login-form/cdc-login-form-component.service.ts:L34-L66, integration-libs/cdc/root/service/cdc-js.service.ts:L181-L192.
2. **Come fa CDC a ottenere un token OAuth Commerce senza passare da** `angular-oauth2-oidc`**?** Con una POST al token endpoint con `grant_type=custom` e i dati firmati di Gigya, poi scrivendo direttamente le chiavi (`access_token`, `expires_at`, …) nell'`AuthStorageService` e dispatchando `AuthActions.Login()`. — integration-libs/cdc/core/auth/services/user-authentication/cdc-user-authentication-token.service.ts:L43-L60, integration-libs/cdc/core/auth/facade/cdc-auth.service.ts:L106-L145.
3. **Che cosa carica la prima chiamata a** `CdcAuthFacade.loginWithCustomCdcFlow` **e perché funziona anche senza** `subscribe`**?** Risolve la feature `cdcCore`, alias di `cdc`, e carica `CdcModule`; `facadeFactory` rende la chiamata eager con `connectable(...).connect()`. — integration-libs/cdc/root/facade/cdc-auth.facade.ts:L11-L33, integration-libs/cdc/root/cdc-root.module.ts:L40-L51, core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts:L70-L82.
4. **Perché in un'app CDC la route di login non reindirizza mai al server OAuth anche con Authorization Code Flow?** Perché `LoginGuard` è sovrascritto con `CdcLoginGuard`, il cui `shouldRenderCMSPage()` ritorna sempre `true`, quindi il ramo `loginWithRedirect()` del guard base non si attiva. — integration-libs/cdc/root/cdc-root.module.ts:L57-L59, integration-libs/cdc/root/guards/cdc-login.guard.ts:L20-L32, core-libs/storefront/cms-components/user/login-route/login.guard.ts:L34-L65.
5. **Dare un consenso che esiste solo in OCC fa chiamate a CDC?** No: `CdcUserConsentAdapter.giveConsent` verifica la presenza dell'id in `cdc-consents-list` e, se la lista esiste e non lo contiene, delega a `super.giveConsent` (OCC); se la lista non è mai stata persistita, `checkIfConsentExists` lancia `TypeError` e nessuna delle due chiamate parte (integration-libs/cdc/root/consent-management/services/cdc-consents-local-storage.service.ts:L69-L76). Se presente, chiama prima CDC e poi OCC solo con `errorCode === 0`. — integration-libs/cdc/root/consent-management/cdc-user-consent.adapter.ts:L35-L65.
6. **Perché** `CdcAdministrationModule` **include** `userCmsConfig.cmsComponents?.ManageUsersListComponent?.providers` **nel proprio array?** Perché `deepMerge` sostituisce gli array: senza riaccodarli si perderebbero i provider originali `ListService → UserListService` e `ItemService → UserItemService`. — integration-libs/cdc/organization/administration/cdc-administration.module.ts:L23-L43, feature-libs/organization/administration/components/user/user.config.ts:L42-L53, core-libs/core/src/config/utils/deep-merge.ts:L36-L45.
7. **Un evento di navigazione su PDP viene inviato a ProfileTag se l'utente non ha dato il consenso** `PROFILE`**?** No: `trackEvents` inoltra sempre `ConsentChanged`, ma gli altri eventi passano il `filter` solo se l'ul-

timo consenso è `granted`. — integration-libs/cds/src/profiletag/tracking/tracking.service.ts:L28-L48, integration-libs/cds/src/profiletag/services/profile-tag-lifecycle.service.ts:L28-L54.

8. **Perché il merchandising carousel è vuoto nell'HTML renderizzato lato server?** Perché `CdsMerchandisingStrategyAdapter.loadProductsForStrategy` ritorna `{ products: [] }` quando `windowRef.isBrowser()` è falso. — integration-libs/cds/src/merchandising/adapters/strategy/cds-merchandising-strategy.adapter.ts:L30-L36.
9. **Come arriva l'header `Segmentrefs` alle chiamate OCC e quale nome ha realmente?** `OccSegmentRefsInterceptor` legge `?segmentrefs=` (o localStorage `segment-refs`) nel costruttore e, solo in browser e per URL OCC, aggiunge l'header col nome `segmentRefs.httpHeaderName` in minuscolo (`segmentrefs`). — integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L39-L60, integration-libs/segment-refs/root/http-interceptors/occ-segment-refs.interceptor.ts:L69-L86, integration-libs/segment-refs/root/config/default-segment-refs-config.ts:L9-L13.
10. **Che cosa cambia CDP nel customer ticketing e con quale meccanismo?** Sostituisce tre component service con varianti che disabilitano chiusura, riapertura e invio messaggi, tramite provider di NgModule importato dopo `CustomerTicketingModule`. — integration-libs/cdp/customer-ticketing/cdp-customer-ticketing.module.ts:L17-L35, integration-libs/cdp/customer-ticketing/cdp-customer-ticketing-close-component.service.ts:L12-L16, core-libs/schematics/src/shared/lib-configs/integration-libs/cdp-schematics-config.ts:L28-L40.

4. Diagrammi
5. Estratti di codice reale
6. Configurazione
7. Commenti e note notevoli dal sorgente
8. Extension point
9. Trappole, casi limite, comportamenti controintuitivi
10. Come fare debug
11. Domande di autoverifica

Riferimenti allo SHA `5b7a1c2bf2808d7380bc20596d10f4fa710c3da1` (vedi 00-meta).

Prerequisiti consigliati: 12 — Feature module e lazy loading (featureModules, `facadeFactory`), 20 — Facade, command & query, eventi, 26 — Checkout (flow, step, guard: OPF li sostituisce), 21 — Livello OCC (adapter, converter, endpoint). Collegati: 25 — Carrello, 27 — Ordini (`placePaymentAuthorizedOrder`), 17 — Outlet, 41 — Errori e global message, 42 — Feature toggle, 01 — Dependency injection.

1. A cosa serve e perché esiste

Questo capitolo copre tre librerie di `integration-libs/`, cioè funzionalità che richiedono un backend o un add-on specifico oltre a SAP Commerce standard:

LIBRERIA	COS'È (DAL README)	FORMA NEL CODICE
`@spartacus/opf`	integrazione del "SAP Commerce Open Payment Framework" (`integration-libs/opf/README.md:L1-L3`)	10 sotto-cartelle (base, payment, checkout, b2b-checkout, cta, global-functions, quick-buy, gift-card, tokenisation, order), ciascuna con secondary entry point; il `public_api.ts` radice è vuoto (`integration-libs/opf/public_api.ts:L14-L16`)
`@spartacus/digital-payments`	integrazione di "SAP Digital payments" (`integration-libs/digital-payments/README.md:L1-L3`)	un solo modulo che si innesta nel checkout standard (`integration-libs/digital-payments/src/digital-payments.module.ts:L10-L13`)
`@spartacus/opps`	"Omnichannel Promotion Pricing Service", estensione di Personalization (`integration-libs/opps/README.md:L1-L4`)	solo un root module eager: coupon da URL + guard di login (`integration-libs/opps/root/opps-root.module.ts:L13-L17`)

OPF è di gran lunga la parte più grande ed è il cuore del capitolo. Il suo problema di fondo: il pagamento non passa da OCC ma da un servizio esterno (il "commerce cloud adapter" OPF, a cui si arriva via `opf.opfBaseUrl`, `projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L186-L193`), che restituisce le **configurazioni di pagamento attive** e, per ciascuna, uno di tre *render pattern*: `IFRAME`, `FULL_PAGE`, `HOSTED_FIELDS` (`integration-libs/opf/payment/root/model/opf-payment.model.ts:L250-L254`). Lo storefront deve quindi:

1. leggere le configurazioni attive e mostrarle come opzioni di pagamento (`integration-libs/opf/base/opf-api/adapters/opf-api-base.adapter.ts:L65-L80`);
2. "iniziare" una sessione di pagamento sul servizio OPF e renderizzare quello che il PSP restituisce: un iframe, un redirect/form a pagina intera, oppure script e HTML del PSP (`integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L284-L331`);
3. esporre agli script del PSP un'**API JavaScript globale** (`window.Opf.payments[domain]`) per fare submit, mostrare spinner, ricevere il 3DS (`integration-libs/opf/global-functions/core/facade/opf-global-functions.service.ts:L73-L88`);
4. gestire il **ritorno dal PSP** su una route dedicata che verifica il pagamento e piazza l'ordine (`integration-libs/opf/payment/root/opf-payment-root.module.ts:L18-L39`);
5. piazzare l'ordine con `OrderFacade.placePaymentAuthorizedOrder` invece del place order classico (`integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L229-L231`).

Tre scelte progettuali dominano tutto OPF:

- **Ogni sotto-feature è una mini feature lib.** Root module eager + modulo lazy registrato in `featureModules`; facade astratte in `root` con `facadeFactory`, implementazioni in `core` legate con `useExisting` (`integration-`

libs/opf/base/root/facade/opf-base.facade.ts:L16-L25, integration-libs/opf/base/core/facade/facade-providers.ts:L11-L17). È lo schema del capitolo 12.

- **Override via DI di pezzi di core e di altre feature.** OPF sostituisce `GlobalMessageService`, `CheckoutAuthGuard`, `CheckoutB2BStepsSetGuard`, `CheckoutPaymentTypeFacade`, `UserPaymentAdapter`, e aggiunge normalizer e interceptor multi-provider (tabella in §8). È il tema "override via DI" richiesto dall'outline e lo trattiamo con attenzione perché ogni override ha uno *scope* (root o lazy) diverso.
- **Stato senza NgRx.** Lo stato OPF è un `BehaviorSubject` (`OpfMetadataStoreService`) sincronizzato in storage (integration-libs/opf/base/root/services/opf-metadata-store.service.ts:L11-L39, integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L34-L47); le chiamate backend sono `Query`/`Command` (integration-libs/opf/payment/core/facade/opf-payment.service.ts:L36-L117).

Digital Payments e OPPS sono molto più piccoli e li trattiamo in fondo a §3.

---

2. Mappa dei file

OPF (radice `integration-libs/opf/`)

PATH	RUOLO
`integration-libs/opf/public_api.ts`	Barrel vuoto: solo `types.d.ts` + `export {}` (:L14-L16).
`integration-libs/opf/_index.scss`	Importa gli SCSS delle sotto-feature con stili (base, checkout, b2b-checkout, cta, payment, quick-buy, gift-card, tokenisation; non `global-functions` né `order`) e definisce `$opf-components-allowlist` (:L1-L24).
`integration-libs/opf/base/opf-base.module.ts`	Modulo lazy `OpfBaseModule` = api + core + components (:L12-L15).
`integration-libs/opf/base/root/opf-base-root.module.ts`	App initializer di persistenza, override `GlobalMessageService`, `defaultOpfConfig` (:L16-L32).
`integration-libs/opf/base/root/config/opf-config.ts`	`OpfConfig` (abstract, `useExisting: Config`) + augmentation di `Config` (:L10-L94).
`integration-libs/opf/base/root/config/constants.ts`	Header `sap-commerce-cloud-public-key` / `sap-commerce-cloud-access-code` (:L7-L8).
`integration-libs/opf/base/root/services/opf-metadata-store.service.ts`	Stato OPF in un `BehaviorSubject` (:L11-L39).
`integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts`	Sync con storage, chiave `'opf'` (:L34-L93).
`integration-libs/opf/base/root/services/opf-resource-loader.service.ts`	Caricamento script/CSS del PSP, esecuzione HTML/JS (:L100-L436).
`integration-libs/opf/base/root/services/opf-global-message.service.ts`	`GlobalMessageService` con chiavi silenziabili (:L19-L60).

PATH	RUOLO
integration-libs/opf/base/root/events/opf-event.listener.ts	Reset metadata su login/ordine/nuovo carrello (:L27-L35).
integration-libs/opf/base/core/services/opf-endpoints.service.ts	Costruzione URL OPF API (:L40-L96).
integration-libs/opf/base/opf-api/adapters/opf-api-base.adapter.ts	GET active configurations (:L65-L118).
integration-libs/opf/payment/root/opf-payment-root.module.ts	Route di verifica + location initializer (:L18-L49).
integration-libs/opf/payment/root/facade/opf-payment.facade.ts	OpfPaymentFacade (7 metodi, feature opfPayment) (:L22-L39).
integration-libs/opf/payment/root/components/opf-payment-verification/*	Componente e servizio della pagina di ritorno dal PSP.
integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts	Submit / submit-complete e gestione dello status (:L62-L235).
integration-libs/opf/payment/opf-api/adapters/opf-api-payment.adapter.ts	verify/submit/submitComplete/afterRedirect/initiate/update (:L85-L308).
integration-libs/opf/payment/occ/adapters/occ-opf-payment.adapter.ts	PUT paymentOption sul carrello OCC (:L29-L71).
integration-libs/opf/checkout/root/opf-checkout-root.module.ts	Override CheckoutAuthGuard, flow OPF, routing, app initializer orchestratore (:L26-L63).
integration-libs/opf/checkout/components/opf-checkout-payments/*	Lista opzioni di pagamento.
integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/*	Iniziazione pagamento e rendering PSP (service, component, directive sandbox).
integration-libs/opf/b2b-checkout/root/opf-b2b-checkout-root.module.ts	Override CheckoutB2BStepsSetGuard, flow OPF B2B (:L19-L48).
integration-libs/opf/b2b-checkout/core/facade/facade-providers.ts	Override CheckoutPaymentTypeFacade (:L11-L17).
integration-libs/opf/cta/**	Script "call to action" del PSP su PDP/carrello/ordine.
integration-libs/opf/global-functions/core/facade/opf-global-functions.service.ts	Registrazione window.Opf.payments[domain] (:L32-L102).
integration-libs/opf/global-functions/core/services/**	Implementazione delle funzioni per i domini checkout/global/redirect.

PATH	RUOLO
integration-libs/opf/quick-buy/**	Google Pay / Apple Pay "quick buy" (anche da PDP con carrello dedicato).
integration-libs/opf/gift-card/**	Gift card come metodo STORED_VALUE_PAYMENT, normalizer e interceptor.
integration-libs/opf/tokenisation/**	Carte salvate, override UserPaymentAdapter.
integration-libs/opf/order/opf-order.module.ts	Normalizer ordine (billing address) (:L11-L20).

Digital Payments e OPPS

PATH	RUOLO
integration-libs/digital-payments/public_api.ts	Esporta src/checkout/index e DigitalPaymentsModule (:L10-L11).
integration-libs/digital-payments/src/checkout/dp-checkout.module.ts	Adapter, normalizer, endpoint, DpCheckoutPaymentService (:L21-L42).
integration-libs/digital-payments/src/checkout/adapters/occ-digital-payments.adapter.ts	POST request/response con query param sid/sign (:L36-L95).
integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.module.ts	Rimappa il CMS CheckoutPaymentDetails (:L23-L45).
integration-libs/digital-payments/src/checkout/facade/dp-checkout-payment.service.ts	Query request + Command details (:L36-L114).
integration-libs/opps/root/opps-root.module.ts	OppsRootModule (:L13-L17).
integration-libs/opps/root/config/default-opps-config.ts	Default nomi header/param/storage (:L9-L20).
integration-libs/opps/root/coupon-codes/**	Location initializer + interceptor coupon.
integration-libs/opps/root/login-required/*	OppsLoginRequiredGuard su BEFORE_CMS_PAGE_GUARD.

Wiring nell'app demo

PATH	RUOLO
projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts	9 root module eager, 9 featureModules, config OPF, scelta B2B/B2C (:L73-L197).
projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts	OpfOrderModule dentro il chunk order (:L21-L26).
projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts	DigitalPaymentsModule dentro il chunk checkout (:L22-L33).
projects/storefrontapp/src/app/spartacus/features/opps/opps-feature.module.ts	Import eager di OppsRootModule (:L10-L13).

File aggiuntivi

PATH	RUOLO
`integration-libs/digital-payments/assets/public_api.ts`	entry point `assets` di digital-payments: riesporta `translations/translations` (chunk `dpPaymentForm` e traduzioni per lingua)
`integration-libs/digital-payments/schematics/add-digital-payments/index.ts`	rule `ng add` di `@spartacus/digital-payments` (`addDigitalPaymentsFeature`)
`integration-libs/digital-payments/schematics/add-digital-payments/index_spec.ts`	test Jest dello schematic DP (registra la collection checkout e installa prima checkout base)
`integration-libs/opf/schematics/add-opf/index.ts`	rule `ng add` di `@spartacus/opf` (`addOpfFeature`)
`integration-libs/opf/schematics/add-opf/index_spec.ts`	test Jest dello schematic OPF per le feature base, checkout, payment, CTA, global functions, quick buy, gift card, tokenisation
`integration-libs/opps/public_api.ts`	entry point primario `@spartacus/opps`: riesporta `root/public_api`
`integration-libs/opps/schematics/add-opps/index.ts`	rule `ng add` di `@spartacus/opps` (`addOppsFeature`)
`integration-libs/opps/schematics/add-opps/index_spec.ts`	test Jest dello schematic OPPS (richiede prima personalization)

3. Come funziona passo per passo

3.1 Wiring: root module eager, moduli lazy, scelta B2B/B2C

1. **Nove root module eager.** L'app importa `OpfBaseRootModule`, `OpfPaymentRootModule`, `OpfCheckoutRootModule`, `OpfB2bCheckoutRootModule`, `OpfCtaRootModule`, `OpfGlobalFunctionsRootModule`, `OpfQuickBuyRootModule`, `OpfGiftCardRootModule`, `OpfTokenisationRootModule` (projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L92-L103). Questi contengono solo config di default, facade proxy, route, override DI e i componenti che devono esistere subito.
2. **Nove moduli lazy.** Ogni feature name punta a un `import()` dinamico in `featureModules`; per `OPF_QUICK_BUY_FEATURE` l'app carica la variante `@spartacus/opf/quick-buy/pickup-in-store` (`OpfQuickBuyPickupInStoreModule`) e non `OpfQuickBuyModule` (projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L105-L152).
3. **Facade proxy.** Una facade OPF è una classe astratta `providedIn: 'root'` con `useFactory: () => facadeFactory({facade, feature, methods})` (integration-libs/opf/base/root/facade/opf-base.facade.ts:L16-L25). `facadeFactory` delega a `FacadeFactoryService.create`, che restituisce un proxy che carica la feature "at first method call" (core-libs/core/src/lazy-loading/facade-factory/facade-factory.ts:L10-L23). Dentro il modulo lazy, `facadeProviders` lega la facade al servizio concreto con `useExisting` (integration-libs/opf/base/core/facade/facade-providers.ts:L11-L17).
4. **Config di base.** `defaultOpfConfig` mette `opfBaseUrl: ''` e `paymentOption.enableInfoMessage: true` (integration-libs/opf/base/root/config/default-opf-config.ts:L9-L16); l'app fornisce URL reale, una public key segnaposto e `enableGetActiveConfigurationsAccessCodeHeader: true` (projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L186-L193).
5. **B2B o B2C a build time.** Sia `OpfCheckoutRootModule` sia `OpfB2bCheckoutRootModule` forniscono come *default* un `checkout.flows.OPF` (3 step il primo, 5 il secondo) (integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L56-L56, integration-libs/opf/b2b-checkout/root/opf-b2b-checkout-root.

module.ts:L43-L43). Poiché deepMerge sostituisce i valori non oggetto, array di step compresi (core-libs/core/src/config/utils/deep-merge.ts:L31-L46), i due default si sovrascrivono; l'app decide esplicitamente con provideConfig in base a environment.b2b (projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L73-L81). Allo stesso modo le config gift card sono aggiunte solo se !environment.b2b && environment.opf (projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L85-L91).

6. **Order fuori da OPF lazy.** OpfOrderModule non è una feature: l'app lo mette accanto a OrderModule dentro OrderWrapperModule (projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L21-L26), e il modulo aggiunge OpfOccOrderNormalizer a ORDER_NORMALIZER, che copia sapBillingAddress in paymentInfo.billingAddress se assente (integration-libs/opf/order/opf-order.module.ts:L11-L20, integration-libs/opf/order/opf-occ-order-normalizer.ts:L13-L28).
7. **Feature toggle.** Tre toggle di core, default false, cambiano il comportamento OPF: opfPaymentVerificationCheckProcessingCartOnErrorOnly, opfUseDestroyRef, opfCheckoutUseUpdatePaymentTransaction; l'app demo li abilita tutti (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1074-L1083, projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L364-L371).

3.2 OPF base: stato, persistenza, URL, active configurations

1. **All'avvio** OpfBaseRootModule registra con provideAppInitializer una funzione che chiama OpfMetadataStatePersistanceService.initSync() (integration-libs/opf/base/root/opf-base-root.module.ts:L19-L24); in Angular provideAppInitializer è solo un valore del multi-token APP_INITIALIZER (angular:packages/core/src/application/application_init.ts:L192-L202).
2. initSync collega lo stato a StatePersistenceService.syncWithStorage con chiave 'opf'; alla lettura chiama updateOpfMetadata (integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L34-L47, integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L89-L93).
3. **Cosa viene persistito.** Tutto il metadata tranne opfPaymentSessionId e opfPaymentSessionConfigurationId, che sono salvati solo se is3DSRedirect è vero, perché devono sopravvivere al reload della pagina del PSP (integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L62-L83).
4. **Lo stato** è un BehaviorSubject<OpfMetadataModel> con stato iniziale congelato (termsAndConditionsChecked, selectedPaymentOptionId, isPaymentInProgress, opfPaymentSessionId, is3DSRedirect, opf3DSRedirectReturnPath, ...) e tre operazioni: get, update parziale, clear (integration-libs/opf/base/root/services/opf-metadata-store.service.ts:L11-L39).
5. **Reset.** OpfEventListenerService azzera lo stato su LoginEvent, OrderPlacedEvent, CreateCartEvent; viene istanziato perché OpfEventModule lo inietta nel costruttore (integration-libs/opf/base/root/events/opf-event.listener.ts:L27-L35, integration-libs/opf/base/root/events/opf-event.module.ts:L10-L15).
6. **Override di** GlobalMessageService**.** Lo stesso root module fornisce { provide: GlobalMessageService, useExisting: OpfGlobalMessageService } (integration-libs/opf/base/root/opf-base-root.module.ts:L25-L28). OpfGlobalMessageService estende il servizio di core e scarta i messaggi la cui key è in disabledKeys mentre il blocco è attivo; disableGlobalMessage(keys, timeout) lo attiva per timeout ?? 2000 ms (integration-libs/opf/base/root/services/opf-global-message.service.ts:L19-L60). Effetto: **tutta l'app** (non solo OPF) usa questa sottoclasse.
7. **URL OPF.** OpfEndpointsService.buildUrl compone ${opfBaseUrl}/${activeBaseSite}/${endpoint}, risolvendo urlParams con StringTemplate.resolve e aggiungendo queryParams con HttpParamsURIEncoder (integration-libs/opf/base/core/services/opf-endpoints.service.ts:L40-L75). L'endpoint viene da backend.opfApi.endpoints, che OpfApiConfig aggiunge a BackendConfig per augmentation (integration-

libs/opf/base/core/services/opf-endpoints.service.ts:L77-L88, integration-libs/opf/base/root/config/opf-api-config.ts:L11-L21). L'interfaccia `OpfApiEndpoints` è vuota e ogni sotto-feature la estende (integration-libs/opf/base/root/model/opf-api-endpoints.model.ts:L7-L7, integration-libs/opf/base/opf-api/model/opf-api-base-endpoints.model.ts:L9-L16).

8. **Base site.** `_activeBaseSite` è riempito in modo asincrono dal costruttore con `baseSiteService.getActive().subscribe(...)` (integration-libs/opf/base/core/services/opf-endpoints.service.ts:L26-L38).
9. **Active configurations.** `OpfBaseService.getActiveConfigurationsState(query)` crea **a ogni chiamata** una nuova `Query` su `OpfBaseConnector.getActiveConfigurations(query)` e ne restituisce `getState()` (integration-libs/opf/base/core/facade/opf-base.service.ts:L23-L34). L'adapter fa GET con header JSON + `Accept-Language`, la public key e, se `enableGetActiveConfigurationsAccessCodeHeader`, l'access code del carrello ottenuto da `CartAccessCodeFacade.getCartAccessCode(userId, cartId)`; normalizza l'errore con `tryNormalizeHttpError` e applica `OPF_ACTIVE_CONFIGURATIONS_NORMALIZER` (integration-libs/opf/base/opf-api/adapters/opf-api-base.adapter.ts:L65-L118). Endpoint di default: `active-configurations` (integration-libs/opf/base/opf-api/config/default-opf-api-base-config.ts:L9-L17).
10. **Modello.** Una `OpfActiveConfiguration` ha `id`, `providerType`, `paymentType`, `displayName`, `logoUrl`, `dynamicScript`…; `OpfPaymentProviderType` = `PAYMENT_GATEWAY` | `PAYMENT_METHOD` | `STORED_VALUE_PAYMENT` (integration-libs/opf/base/root/model/opf-base.model.ts:L12-L23, integration-libs/opf/base/root/model/opf-base.model.ts:L84-L88).

3.3 Il resource loader: come arriva il codice del PSP nella pagina

`OpfResourceLoaderService` è il punto in cui codice di terze parti entra nello storefront.

1. **SSR: niente.** `loadResources` in server risolve subito, con il commento "SSR mode not supported for security concerns" (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L397-L406).
2. **Locale o esterno.** Se `opf.localPspResources[paymentOptionId]` esiste si usano quei file JS/CSS, altrimenti gli URL ricevuti dal backend (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L408-L416, integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L316-L345).
3. **Script.** Iniettati con `ScriptLoader.embedScript` e `disableKeyRestriction: true`; con `sri` si impostano `integrity` e `crossOrigin` (default `'anonymous'`) (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L124-L149).
4. **Marcatura per la pulizia.** Ogni risorsa riceve `data-opf-resource="true"`, salvo attributo `opf-load-once: 'true'`; `clearAllResources` rimuove tutti i nodi marcati (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L100-L115, integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L186-L194).
5. **Modalità `SEPARATE`.** Se `dynamicScript.htmlContentMode === SEPARATE`, il JS arriva in `jsContent` e il contesto in `jsContext` (JSON); il CSS `cssUrl+cssHash` è aggiunto agli stili con SRI (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L277-L311). Dopo il caricamento, `executeScriptWithContext` imposta `window.OpfContext`, inserisce uno `<script data-opf-script>` **fuori dalla zone** e lo rimuove dopo 100 ms (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L232-L261, integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L429-L435).
6. **Modalità HTML classica.** `executeScriptFromHtml` (solo browser) estrae il primo `<script>` dall'HTML con `DOMParser` ed esegue il contenuto con `Function(...)()` (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L174-L184).

3.4 Checkout OPF B2C: dal flow alla scelta dell'opzione

1. **Flow per payment provider.** `CheckoutFlowOrchestratorService` (lib checkout) legge `baseSite.baseStore.paymentProvider` e, se esiste `checkout.flows[paymentProvider]`, restituisce quel flow invece della config standard (feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L20-L44); `CheckoutStepService.resetSteps` usa gli step di quel flow (feature-libs/checkout/base/components/services/checkout-step.service.ts:L88-L94). OPF definisce il flow `OPF` (integration-libs/opf/checkout/root/model/opf-checkout.model.ts:L13-L13).
2. **Istanziazione precoce.** `OpfCheckoutRootModule` forza la creazione dell'orchestratore con `provideAppInitializer(() => { inject(CheckoutFlowOrchestratorService); })` (integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L58-L60): il costruttore sottoscrive `getPaymentProvider()` (con `take(1)`) e memorizza il nome (feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L20-L33).
3. **Step B2C.** `deliveryAddress` (route standard `checkoutDeliveryAddress`), `deliveryMode`, `opfPaymentAndReview` (route `opfCheckoutPaymentAndReview`, tipo `PAYMENT_DETAILS`) con `guest: false` (integration-libs/opf/checkout/root/config/default-opf-checkout-config.ts:L12-L45). Route semantiche OPF: `checkout/opf-payment-type`, `checkout/opf-delivery-address`, `checkout/opf-payment-and-review`, `checkout/opf-review`, `opf-checkout-email` (integration-libs/opf/checkout/root/config/default-opf-checkout-routing-config.ts:L9-L29).
4. **Guard sostituito.** Il root module fornisce `{ provide: CheckoutAuthGuard, useClass: OpfCheckoutAuthGuard }` (integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L44-L47). `OpfCheckoutAuthGuard` estende il guard standard: carrello non guest → `super.canActivate()`; carrello guest → verifica via OCC (`users/${userId}/carts/${cartId}?fields=sapCustomerEmail`) che il guest abbia un'email, altrimenti `UrlTree` verso `opfCheckoutEmail` (integration-libs/opf/checkout/root/checkout-guard/opf-checkout-auth.guard.ts:L33-L62, integration-libs/opf/checkout/root/config/default-occ-opf-checkout-config.ts:L9-L18). La pagina email aggiorna il guest con `CartGuestUserFacade.updateCartGuestUser`, ricarica il carrello e va a `checkoutDeliveryAddress` (integration-libs/opf/checkout/components/opf-checkout-email-update/opf-checkout-email-update.component.ts:L75-L91).
5. **Componente CMS.** `OpfCheckoutPaymentAndReview` (feature lazy `opfCheckout`) è mappato su `OpfCheckoutPaymentAndReviewComponent` con guard `[CheckoutAuthGuard, CartNotEmptyGuard]` (integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L26-L40, integration-libs/opf/checkout/components/opf-checkout-payment-and-review/opf-checkout-payment-and-review.module.ts:L57-L66). Il componente estende `CheckoutReviewSubmitComponent`, gestisce il form T&C con `Validators.requiredTrue` e scrive `termsAndConditionsChecked` nel metadata store (integration-libs/opf/checkout/components/opf-checkout-payment-and-review/opf-checkout-payment-and-review.component.ts:L74-L141).
6. **T&C esplicito.** È attivo se il JSON della pagina CMS contiene la stringa `OpfExplicitTermsAndConditionsComponent` (integration-libs/opf/checkout/components/opf-checkout-payment-and-review/opf-checkout-payment-and-review.component.ts:L103-L131, integration-libs/opf/checkout/root/model/opf-checkout.model.ts:L10-L11). Con T&C esplicito non accettato la preselezione dell'opzione di pagamento viene azzerata (integration-libs/opf/checkout/components/opf-checkout-payments/opf-checkout-payments.component.ts:L266-L322).
7. **Carrello solo pickup.** Se non ci sono delivery items il componente cancella l'indirizzo di consegna e imposta delivery mode `'pickup'` (integration-libs/opf/checkout/components/opf-checkout-payment-and-review/opf-checkout-payment-and-review.component.ts:L147-L161).
8. **Lista opzioni.** `OpfCheckoutPaymentsComponent` chiede le configurazioni paginando (`pageSize`, `pageNumber: index+1`), esclude `STORED_VALUE_PAYMENT` (gestite dalla gift card) e, in modalità "solo wrapper", tiene solo quella selezionata (integration-libs/opf/checkout/components/opf-checkout-payments/opf-checkout-payments.component.ts:L199-L238). Il messaggio informativo viene da `opf.paymentOption.`

`paymentInfoMessagesMap[paymentId]` con fallback `opfCheckout.defaultPaymentInfoMessage` (integration-libs/opf/checkout/components/opf-checkout-payments/opf-checkout-payments.component.ts:L244-L260). La selezione scrive `selectedPaymentOptionId` nel metadata store (integration-libs/opf/checkout/components/opf-checkout-payments/opf-checkout-payments.component.ts:L350-L357).

3.5 Iniziazione del pagamento e rendering del PSP

1. **Iniziazione.** `OpfCheckoutPaymentWrapperService.initiatePayment(paymentOptionId)` emette lo stato "loading", pulisce le risorse, imposta `isPaymentInProgress: true`, ottiene l'OTP con `CartAccessCodeFacade.getCartAccessCode` e chiama `OpfPaymentFacade.initiatePayment` (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L103-L168).
2. **Config di iniziazione.** `configurationId = String(paymentOptionId)`, `channel: BROWSER`, `browserInfo`, e `resultURL`/`cancelURL` calcolati con `routingService.getFullUrl` sulle route di verifica (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L399-L418). `getBrowserInfo` raccoglie colorDepth, lingua, schermo, userAgent, origin e timezone (integration-libs/opf/payment/core/utils/opf-payment-utils.ts:L9-L24).
3. **Update invece di initiate.** Con il toggle `opfCheckoutUseUpdatePaymentTransaction` e una sessione salvata per la *stessa* configurazione, si chiama `updatePaymentTransaction`; un 409 ricade su `initiatePayment` (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L137-L168, integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L239-L255). La sessione viene salvata solo con il toggle o per pattern `FULL_PAGE` (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L192-L208).
4. **HTTP.** `OpfApiPaymentAdapter.initiatePayment` passa la config per `OPF_PAYMENT_CONFIG_SERIALIZER` e fa POST di `paymentConfig.config` su `payments`, con public key e `otpKey` nell'header access code; `updatePaymentTransaction` fa PUT su `payments/${paymentSessionId}` (integration-libs/opf/payment/opf-api/adapters/opf-api-payment.adapter.ts:L196-L256, integration-libs/opf/payment/opf-api/config/default-opf-api-payment-config.ts:L9-L23).
5. **Rendering.** `renderPaymentGateway`: se c'è `dynamicScript` carica le risorse (vedi §3.3), emette l'evento di rendering e, salvo `SEPARATE`, esegue l'HTML; altrimenti se c'è `destination` emette l'evento con l'URL; altrimenti errore generico. `dynamicScript` ha la precedenza (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L275-L331). L'HTML viene eseguito solo se l'utente è ancora sulla route `opfCheckoutPaymentAndReview` (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L74-L93).
6. **Template.** `FULL_PAGE` diventa link o form `_self`, `IFRAME` un `<iframe>` (eventualmente alimentato da un form POST con target `cx-payment-iframe`) con direttiva `cxOpfSandbox` (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.component.html:L15-L69). La direttiva imposta o rimuove `sandbox`; il valore viene da `opf.paymentOption.iframeSandboxMap[paymentOptionId]` (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-iframe-sandbox.directive.ts:L9-L25, integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.component.ts:L111-L117).
7. **Hosted fields.** Se la risposta ha `paymentSessionId` e pattern `HOSTED_FIELDS`, il componente registra le global functions del dominio `checkout`, altrimenti le rimuove; in `ngOnDestroy` le rimuove e pulisce le risorse (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.component.ts:L208-L253, integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.component.ts:L125-L131).
8. **Re-iniziazione.** Al cambio di lingua o valuta (saltato il valore iniziale, atteso il carrello stabile) il wrapper emette `reinitiatePaymentEvent$` (integration-libs/opf/checkout/components/opf-checkout-payment-

wrapper/opf-checkout-payment-wrapper.component.ts:L164-L199). Lo stesso canale è usato dalla gift card e dallo script PSP (`reinitiatePaymentForm`) (integration-libs/opf/payment/root/services/opf-payment-events.service.ts:L14-L50).

9. **409 all'iniziazione** = "pagamento già fatto": si piazza l'ordine e si va a conferma (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L333-L367).

3.6 Global functions: l'API JavaScript per gli script del PSP

1. **Domini.** `OpfGlobalFunctionsDomain = checkout | global | redirect` (integration-libs/opf/global-functions/root/model/opf-global-functions.model.ts:L10-L14).
2. **Registrazione.** `OpfGlobalFunctionsService.registerGlobalFunctions` (solo browser) crea se serve `window.Opf.payments[domain]` e delega al servizio di registrazione del dominio; `unregisterGlobalFunctions` imposta il contenitore a `undefined` (integration-libs/opf/global-functions/core/facade/opf-global-functions.service.ts:L32-L102).
3. **Dominio** `checkout` (wrapper hosted fields e ritorno 3DS): `submit`, `submitComplete`, `throwPaymentError`, start/stop load indicator, `reinitiatePaymentForm`, `handle3DSRedirect`, `updatePaymentTransaction` (integration-libs/opf/global-functions/core/services/domains/checkout/opf-global-functions-checkout-domain-registrations.service.ts:L21-L45).
4. **Dominio** `redirect` (pagina di verifica, pattern after-redirect): registra solo se c'è `paymentSessionId`: `submit`, `submitCompleteRedirect` (con returnPath `opfCheckoutPaymentAndReview`), `getRedirectParams` (integration-libs/opf/global-functions/core/services/domains/redirect/opf-global-functions-redirect-domain-registrations.service.ts:L24-L38, integration-libs/opf/global-functions/core/services/domains/redirect/opf-global-functions-redirect-domain.service.ts:L22-L42).
5. **Dominio** `global` (CTA e quick buy): `scriptReady`, `getCart`, indirizzi, delivery mode, guest user, `initiatePayment`, `verifyPayment`, `getApplePayWebSession`, ecc. (integration-libs/opf/global-functions/core/services/domains/global/opf-global-functions-global-domain-registrations.service.ts:L33-L69). Le funzioni di carrello delegano a `OpfQuickBuyTransactionService` (integration-libs/opf/global-functions/core/services/domains/global/opf-global-functions-global-domain.service.ts:L179-L266).
6. **Promise + zone.** Ogni funzione restituisce una Promise e gira in `ngZone.run`; `submit` converte l'Observable con `lastValueFrom(... last(() => true, true))` e mostra lo spinner `PLACE_ORDER_SPINNER` se ha un `ViewContainerRef` (integration-libs/opf/global-functions/core/services/opf-global-functions-shared.service.ts:L106-L170, integration-libs/opf/global-functions/core/services/opf-global-functions-shared.service.ts:L268-L291). Il `paymentSessionId` è quello passato o quello del metadata store, altrimenti eccezione `'paymentSessionId is required'` (integration-libs/opf/global-functions/core/services/opf-global-functions-shared.service.ts:L86-L104).
7. **3DS.** `handle3DSRedirect(url)` salva `opfPaymentSessionId`, `is3DSRedirect: true` e `opf3DSRedirectReturnPath` (URL completo della route result), poi naviga a `threeDsURL` (integration-libs/opf/global-functions/core/services/domains/checkout/opf-global-functions-checkout-domain.service.ts:L91-L118). Grazie alla regola di persistenza di §3.2 la sessione sopravvive al reload.

3.7 Submit hosted fields e place order

1. Lo script PSP chiama `window.Opf.payments.checkout.submit(options)` (integration-libs/opf/global-functions/core/services/opf-global-functions-shared-registrations.service.ts:L23-L32) → `OpfGlobalFunctionsSharedService.submit` → `OpfPaymentFacade.submitPayment` (integration-libs/opf/global-functions/core/services/opf-global-functions-shared.service.ts:L150-L168).
2. `OpfPaymentService` incapsula ogni metodo in un `Command`; submit e submit-complete delegano a `OpfPaymentHostedFieldsService` (integration-libs/opf/payment/core/facade/opf-payment.service.

ts:L49-L69).

3. `submitPayment` costruisce la richiesta (`channel: BROWSER`, `browserInfo`, `encryptedToken` svuotato se il metodo non è `CREDIT_CARD`), ottiene l'OTP e chiama il connector (integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L62-L93); l'adapter fa POST su `payments/${paymentSessionId}/submit` con public key, access code e `Accept-Language`, retry su errori 5xx e errori normalizzati con il body copiato (integration-libs/opf/payment/opf-api/adapters/opf-api-payment.adapter.ts:L114-L140, integration-libs/opf/payment/opf-api/adapters/opf-api-payment.adapter.ts:L296-L308).
4. `paymentResponseHandler`: `ACCEPTED`/`DELAYED` → callback `onSuccess` poi `placePaymentAuthorizedOrder(true, cartId)`; `CANCELLED` con `onCancel` e `PENDING` → `EMPTY`; `REJECTED` → errore `PAYMENT_REJECTED`; altro → `STATUS_NOT_RECOGNIZED` (integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L180-L227). Con l'ordine piazzato si naviga a `orderConfirmation` (integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L233-L235).
5. Errori: `OpfPaymentErrorHandlerService` traduce gli errori 400 per tipo (scaduta, fondi insufficienti, carta/CVV non validi, carta smarrita) in chiavi `opfPayment.errors.*`, chiama `onFailure` e naviga a `returnPath` se presente (integration-libs/opf/payment/core/services/opf-payment-error-handler.service.ts:L36-L77). Un 401 (OTP scaduto) fa ripetere **l'intera sequenza**, OTP compreso, con `backOff({ shouldRetry: isAuthorizationError, maxTries: DEFAULT_AUTHORIZATION_ERROR_RETRIES_COUNT })` (integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L115-L122, core-libs/core/src/util/occ-http-error-handlers.ts:L26-L31).

3.8 Ritorno dal PSP: la pagina di verifica

1. **Route senza path.** `OpfPaymentRootModule` registra due route figlie con `path: null` (con `@ts-ignore`) e `data.cxRoute` `paymentVerificationResult`/`paymentVerificationCancel`, entrambe su `OpfPaymentVerificationComponent`; il path reale viene dalla config di routing semantico, di default `opf/payment-verification-redirect/result|cancel` (integration-libs/opf/payment/root/opf-payment-root.module.ts:L18-L39, integration-libs/opf/payment/root/config/default-opf-payment-routing-config.ts:L9-L20).
2. **Cattura della query prima di OAuth.** Un location initializer salva `location.search` in `sessionStorage` (chiave `opfPaymentVerificationQuerySearch`) se il pathname termina con uno dei path di verifica, "before OAuth bootstrap mutates `location.search`" (integration-libs/opf/payment/root/opf-payment-root.module.ts:L42-L46, integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L71-L98). `provideLocationInitializerFactory` contribuisce al multi-token `LOCATION_INITIALIZED_MULTI`, i cui initializer sono eseguiti in parallelo (core-libs/core/src/routing/location-initialized-multi/location-initialized-multi.ts:L43-L51, core-libs/core/src/routing/routing.module.ts:L66-L71). La lettura successiva rimuove la chiave (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L169-L193).
3. **Uscita dall'iframe.** `ngOnInit` per prima cosa, se la pagina è dentro un iframe, ricarica l'URL nella finestra top (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.component.ts:L85-L101).
4. **Carrello in elaborazione.** Senza il toggle `opfPaymentVerificationCheckProcessingCartOnErrorOnly` chiama subito `checkIfProcessingCartIdExist()`; con il toggle solo in caso di errore (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.component.ts:L45-L76). Se `isPaymentInProgress === false`, va al carrello con l'errore `httpHandlers.cartNotFound` (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L266-L283).
5. `verifyResultUrl`. Accetta solo la route result (sulla cancel lancia `opfPayment.errors.cancelPayment`); il `paymentSessionId` viene, in ordine, dallo stato 3DS persistito, dal parametro `opfPaymentSessionId` del-

l'URL, dal metadata store (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L117-L167, integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L195-L215).

6. **Scelta del pattern** (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.component.ts:L103-L137):
   - `is3DSRedirect` → `run3DSRedirectPattern`: registra il dominio `checkout`, chiama `submitCompletePayment` con i parametri dell'URL e il `returnPath` salvato, in `finalize` azzera lo stato 3DS (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L377-L406);
   - `opfAfterRedirectScriptFlag === 'true'` → `runHostedFieldsPattern`: registra il dominio `redirect`, scarica gli after-redirect scripts ed esegue con il resource loader (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L299-L341);
   - altrimenti `runHostedPagePattern`: `verifyPayment` (successo = `AUTHORIZED`/`DELAYED`) → `placePaymentAuthorizedOrder(true)` → conferma ordine (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L236-L252, integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L285-L297).
7. **Errore.** Messaggio globale, cancellazione della sessione per la reiniziazione, ritorno a `opfCheckoutPaymentAndReview` (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.component.ts:L139-L143).

3.9 B2B checkout OPF

1. Flow `OPF` B2B a 5 step (paymentType, deliveryAddress, deliveryMode, paymentAndReview, review) (integration-libs/opf/b2b-checkout/root/config/default-opf-b2b-checkout-config.ts:L13-L55); in B2B l'endpoint `placePaymentAuthorizedOrder` diventa `orgUsers/${userId}/orders?fields=FULL` (integration-libs/opf/b2b-checkout/root/config/default-opf-b2b-checkout-occ-endpoints-config.ts:L10-L22).
2. `OpfB2bCheckoutRootModule` sostituisce `CheckoutB2BStepsSetGuard` con `OpfB2bCheckoutStepsSetGuard` e dichiara 4 componenti CMS lazy (integration-libs/opf/b2b-checkout/root/opf-b2b-checkout-root.module.ts:L19-L48). Il guard disabilita `PAYMENT_DETAILS` per l'account payment e, solo se il provider è `OPF`, `REVIEW_ORDER` per i non-account (integration-libs/opf/b2b-checkout/root/guards/opf-b2b-checkout-steps-set.guard.ts:L70-L117).
3. Nel modulo lazy, `CheckoutPaymentTypeFacade` di `@spartacus/checkout/b2b/root` è rilegata a `OpfB2bCheckoutPaymentTypeService` (integration-libs/opf/b2b-checkout/core/facade/facade-providers.ts:L11-L17), che imposta il tipo di pagamento con `OpfPaymentFacade.setCartPaymentOption` (codice = `sapPaymentOptionId`), `CommandStrategy.CancelPrevious`, e dispatcha `CheckoutPaymentTypeSetEvent` (integration-libs/opf/b2b-checkout/core/facade/opf-b2b-checkout-payment-type.service.ts:L37-L72). L'OCC adapter fa PUT `users/${userId}/carts/${cartId}/paymentOption?fields=DEFAULT` (integration-libs/opf/payment/occ/adapters/occ-opf-payment.adapter.ts:L29-L71).
4. Il componente payment type usa l'`id` della configurazione OPF come codice payment type e abilita/disabilita gli step in base a `ACCOUNT_PAYMENT`: `handlePaymentChange` chiama `adaptCheckoutSteps`, che abilita/disabilita `PAYMENT_DETAILS` e `REVIEW_ORDER` (integration-libs/opf/b2b-checkout/components/opf-b2b-checkout-payment-type/opf-b2b-checkout-payment-type.component.ts:L164-L179, integration-libs/opf/b2b-checkout/components/opf-b2b-checkout-payment-type/opf-b2b-checkout-payment-type.component.ts:L110-L121). Gli altri componenti B2B estendono quelli standard (cost center, delivery ad-

dress, place order) o quello OPF B2C (integration-libs/opf/b2b-checkout/components/opf-b2b-checkout-payment-and-review/opf-b2b-checkout-payment-and-review.component.ts:L45-L46).

3.10 CTA, quick buy, gift card, tokenisation

- **CTA.** `OpfCtaRootModule` dichiara lazy `OpfCtaScriptsComponent` e `OpfCtaQuickBuyButtons` (integration-libs/opf/cta/root/opf-cta-root.module.ts:L11-L25). `OpfCtaScriptsService` mappa il `pageId` CMS a una location (`order`, `orderConfirmationPage`, `productDetails`, `cartPage`) e chiede gli script con POST `payments/cta-scripts-rendering` (integration-libs/opf/cta/components/opf-cta-scripts/opf-cta-scripts.service.ts:L215-L254, integration-libs/opf/cta/opf-api/config/default-opf-api-cta-config.ts:L9-L17). Per le location dinamiche registra il dominio `global` e avvia eventi `CustomEvent` (`opfCartChanged`, `opfProductAmountChanged`) sulla window (integration-libs/opf/cta/components/opf-cta-scripts/opf-cta-scripts.service.ts:L70-L93, integration-libs/opf/cta/core/services/opf-dynamic-cta.service.ts:L180-L234). `OpfCtaElementComponent` toglie i tag `<script>` dall'HTML prima di renderlo (integration-libs/opf/cta/components/opf-cta-element/opf-cta-element.component.ts:L36-L50).
- **Quick buy.** `OpfQuickBuyConfig.providers` contiene `googlePay` e `applePay` con gli URL degli SDK (integration-libs/opf/quick-buy/root/config/default-opf-quick-buy-config.ts:L10-L63). I bottoni appaiono per le configurazioni `PAYMENT_GATEWAY` con `digitalWalletQuickBuy` abilitato (integration-libs/opf/quick-buy/components/opf-quick-buy-buttons/opf-quick-buy-buttons.service.ts:L37-L101). `OpfQuickBuyTransactionService` sceglie il contesto (PDP = singolo prodotto, altrimenti carrello attivo) dalla route semantica (integration-libs/opf/quick-buy/core/services/opf-quick-buy-transaction.service.ts:L36-L47, integration-libs/opf/quick-buy/core/services/opf-quick-buy-transaction.service.ts:L173-L197); sul PDP crea un nuovo carrello non attivo con il solo prodotto (integration-libs/opf/quick-buy/core/services/context/opf-quick-buy-single-product-transaction.service.ts:L307-L341). Il pagamento passa per `OpfPaymentFacade.submitPayment` con `paymentSessionId: ''` e token `btoa` (integration-libs/opf/quick-buy/components/opf-quick-buy-buttons/google-pay/google-pay.service.ts:L497-L516). La variante pickup-in-store rilega `OpfQuickBuySingleProductCartOptionsFacade` per aggiungere `pickupStore` (integration-libs/opf/quick-buy/pickup-in-store/opf-quick-buy-pickup-in-store.module.ts:L12-L22).
- **Gift card.** Il root module aggiunge `OpfGiftCardOrderOccNormalizer` a `ORDER_NORMALIZER`, `OpfGiftCardCartOccNormalizer` a `CART_NORMALIZER` e `OpfGiftCardPaymentApiInterceptor` a `HTTP_INTERCEPTORS` (integration-libs/opf/gift-card/root/opf-gift-card-root.module.ts:L46-L63). L'interceptor agisce solo su `/orders/paymentAuthorizedOrderPlacement`: in errore ricarica il carrello e, se il tipo è `SAPCartStoredValueAuthorizationError`, azzera la sessione e reinizializza il pagamento (integration-libs/opf/gift-card/root/http-interceptors/opf-gift-card-payment-api.interceptor.ts:L38-L65). La gift card è una configurazione `STORED_VALUE_PAYMENT`; la copertura totale è `cart.opfGiftCardSummary.giftCardsCoverFullAmount` (integration-libs/opf/gift-card/core/facade/opf-gift-card.service.ts:L38-L62).
- **Tokenisation.** `OpfTokenisationRootModule` sostituisce `UserPaymentAdapter` di core con `OccOpfTokenisationUserPaymentAdapter` e mette tre componenti nell'outlet `OPF_CHECKOUT_BEFORE_PAYMENT_OPTIONS` (integration-libs/opf/tokenisation/root/opf-tokenisation-root.module.ts:L33-L58). L'adapter carica solo i metodi `saved: true` e in `setDefault` fa PATCH dell'intero dettaglio (integration-libs/opf/tokenisation/root/adapters/occ-opf-tokenisation-user-payment.adapter.ts:L40-L127).

3.11 Digital Payments

1. `DigitalPaymentsModule` importa `DpCheckoutModule` (integration-libs/digital-payments/src/digital-payments.module.ts:L10-L13); l'app lo aggiunge a `CheckoutWrapperModule`, il modulo lazy del checkout, se `environment.digitalPayments` (projects/storefrontapp/src/app/spartacus/features/checkout/

checkout-wrapper.module.ts:L22-L33). DigitalPaymentsFeatureModule fornisce solo le traduzioni (projects/storefrontapp/src/app/spartacus/features/digital-payments/digital-payments-feature.module.ts:L17-L33).

2. DpCheckoutModule lega DigitalPaymentsAdapter → OccDigitalPaymentsAdapter, registra DP_DETAILS_NORMALIZER/DP_REQUEST_NORMALIZER e gli endpoint users/${userId}/carts/${cartId}/payment/digitalPayments/request|response (integration-libs/digital-payments/src/checkout/dp-checkout.module.ts:L21-L42, integration-libs/digital-payments/src/checkout/adapters/config/occ-digital-payments-endpoint.config.ts:L11-L25).
3. DpPaymentMethodModule estende CheckoutPaymentMethodModule e sostituisce il componente CMS CheckoutPaymentDetails con ConfigModule.withConfig, cioè provideConfig e non un default (integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.module.ts:L23-L45, core-libs/core/src/config/config.module.ts:L28-L34).
4. Flusso: DpPaymentFormComponent chiede i dati di registrazione carta (POST .../request), li salva in storage con chiave digital-payment.checkout.request e reindirizza al PSP (integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-form/dp-payment-form.component.ts:L34-L57, integration-libs/digital-payments/src/checkout/facade/dp-local-storage.service.ts:L12-L46). OccDpRequestNormalizer estrae postUrl, session_id e signature (integration-libs/digital-payments/src/checkout/adapters/occ-digital-payment-request.normalizer.ts:L18-L33).
5. Al ritorno, con il query param x-card-registration-status, DpPaymentMethodComponent mostra il callback (integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.component.ts:L46-L93); se lo status è successful si chiede l'indirizzo e si chiama createPaymentDetails, che fa POST con body null e sid/sign/indirizzo come query param (integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-callback/dp-payment-callback.component.ts:L57-L131, integration-libs/digital-payments/src/checkout/adapters/occ-digital-payments.adapter.ts:L48-L84). I nomi dei parametri vengono da digitalPayments.occQueryParams (integration-libs/digital-payments/src/checkout/adapters/config/default-digital-payments-endpoint.config.ts:L9-L25).

3.12 OPPS

1. OppsRootModule importa OppsCouponCodesModule e OppsLoginRequiredModule e fornisce defaultOppsConfig (integration-libs/opps/root/opps-root.module.ts:L13-L17); default: header e parametro couponcodes, storage opps-couponcodes, parametro login loginRequired (integration-libs/opps/root/config/default-opps-config.ts:L9-L20).
2. **Coupon.** Un location initializer legge couponcodes dall'URL e lo salva in localStorage (integration-libs/opps/root/coupon-codes/opps-coupon-codes.module.ts:L12-L29, integration-libs/opps/root/coupon-codes/opps-coupon-codes.service.ts:L18-L31). OccOppsCouponCodesInterceptor (registrato con useExisting) legge il coupon nel costruttore e, nel browser, aggiunge l'header alle richieste verso la base URL OCC (integration-libs/opps/root/coupon-codes/http-interceptors/index.ts:L11-L17, integration-libs/opps/root/coupon-codes/http-interceptors/occ-opps-coupon-codes.interceptor.ts:L28-L64).
3. **Login richiesto.** OppsLoginRequiredGuard è aggiunto al multi-token BEFORE_CMS_PAGE_GUARD (root, factory []): se l'utente è anonimo e c'è ?loginRequired=true, salva l'URL di redirect e rimanda alla pagina di login (integration-libs/opps/root/login-required/opps-login-required.module.ts:L11-L20, integration-libs/opps/root/login-required/opps-login-required.guard.ts:L29-L61, core-libs/storefront/cms-structure/guards/before-cms-page-guard.token.ts:L22-L24).

3.13 Schematic di installazione

`addOpfFeature`, `addDigitalPaymentsFeature` e `addOppsFeature` seguono la sequenza comune: `validateSpartacusInstallation`, `analyzeCrossFeatureDependencies`, poi `chain([analyzeApplication, addFeatures, addPackageJsonDependenciesForLibrary(peerDependencies), finalizeInstallation])` (integration-libs/opf/schematics/add-opf/index.ts:L25-L43, integration-libs/digital-payments/schematics/add-digital-payments/index.ts:L25-L45, integration-libs/opps/schematics/add-opps/index.ts:L25-L43). Gli spec mostrano le dipendenze tra librerie: digital-payments registra la collection di `@spartacus/checkout` prima di generare il workspace (integration-libs/digital-payments/schematics/add-digital-payments/index_spec.ts:L50-L59); OPF registra le collection Spartacus e checkout e ricrea workspace, applicazione e `ng-add` base in un `beforeEach` (integration-libs/opf/schematics/add-opf/index_spec.ts:L111-L147); OPPS installa prima la feature personalization (integration-libs/opps/schematics/add-opps/index_spec.ts:L56-L73). L'entry point primario di OPPS espone solo il root (integration-libs/opps/public_api.ts:L7-L7), mentre `integration-libs/digital-payments/assets/public_api.ts` riesporta le traduzioni (integration-libs/digital-payments/assets/public_api.ts:L7-L7).

5. Estratti di codice reale

Facade proxy in `root`, implementazione in `core` — integration-libs/opf/base/root/facade/opf-base.facade.ts:L16-L25 e integration-libs/opf/base/core/facade/facade-providers.ts:L11-L17:

```ts
@Injectable({
  providedIn: 'root',
  useFactory: () =>
    facadeFactory({
      facade: OpfBaseFacade,
      feature: OPF_BASE_FEATURE,
      methods: ['getActiveConfigurationsState'],
    }),
})
export abstract class OpfBaseFacade {
```

```ts
export const facadeProviders: Provider[] = [
  OpfBaseService,
  {
    provide: OpfBaseFacade,
    useExisting: OpfBaseService,
  },
];
```

Override eager di un servizio di core — integration-libs/opf/base/root/opf-base-root.module.ts:L16-L32:

```ts
@NgModule({
  imports: [OpfEventModule],
  providers: [
    provideAppInitializer(() => {
      const opfStatePersistenceService = inject(
        OpfMetadataStatePersistanceService
      );
      opfStatePersistenceService.initSync();
    }),
    {
      provide: GlobalMessageService,
      useExisting: OpfGlobalMessageService,
    },
    provideDefaultConfig(defaultOpfConfig),
  ],
})
export class OpfBaseRootModule {}
```

Persistenza selettiva della sessione — integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L62-L83:

```ts
  protected getOpfState(): Observable<SyncedOpfState> {
    return this.opfMetadataStoreService.getOpfMetadataState().pipe(
      map((metadata: OpfMetadataModel) => {
        const {
          opfPaymentSessionId,
          opfPaymentSessionConfigurationId,
          ...persistedMetadata
        } = metadata;
        return {
          metadata: {
            ...persistedMetadata,
            // Persist session ID only for 3DS redirect — it must survive the PSP page reload.
            // For other patterns, keeping it in-memory only prevents stale sessions from being reused after a page refresh.
            ...(metadata.is3DSRedirect && {
              opfPaymentSessionId,
              opfPaymentSessionConfigurationId,
            }),
          } as OpfMetadataModel,
        };
      })
    );
  }
```

Override del guard del checkout e istanziazione dell'orchestratore — integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L42-L63:

```ts
@NgModule({
  providers: [
    {
      provide: CheckoutAuthGuard,
      useClass: OpfCheckoutAuthGuard,
    },
    {
      provide: OpfCheckoutAdapter,
      useClass: OpfApiCheckoutAdapter,
    },
    OpfCheckoutConnector,
    OpfCartUserEmailCheckerService,
    provideDefaultConfig(defaultOpfCheckoutRoutingConfig),
    provideDefaultConfig(defaultOccOpfCheckoutConfig),
    provideDefaultConfig(defaultOpfCheckoutConfig),
    provideDefaultConfigFactory(defaultOpfCheckoutComponentsConfig),
    provideAppInitializer(() => {
      inject(CheckoutFlowOrchestratorService);
    }),
```

```
  ],
})
export class OpfCheckoutRootModule {}
```

Scelta del flow per payment provider (lib checkout) — feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L35-L44:

```ts
getCheckoutFlow(): CheckoutFlow | undefined {
  if (this.paymentProviderName) {
    const flow =
      this.checkoutConfig.checkout?.flows?.[this.paymentProviderName];
    if (flow) {
      return flow;
    }
  }
  return this.checkoutConfig.checkout;
}
```

URL OPF — integration-libs/opf/base/core/services/opf-endpoints.service.ts:L40-L48 e :L74-L74:

```ts
buildUrl(endpoint: string, attributes?: DynamicAttributes): string {
  const baseUrl = this.getBaseEndpoint();
  let opfEndpoint = this.getEndpointFromContext(endpoint);
  if (attributes) {
    const { urlParams, queryParams } = attributes;

    if (urlParams && opfEndpoint) {
      opfEndpoint = StringTemplate.resolve(opfEndpoint, urlParams, true);
    }
    // ...
  return `${baseUrl}/${this._activeBaseSite}/${opfEndpoint}`;
```

Gestione dello status di submit — integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L190-L207:

```ts
  if (
    response.status === OpfPaymentSubmitStatus.ACCEPTED ||
    response.status === OpfPaymentSubmitStatus.DELAYED
  ) {
    return from(Promise.resolve(callbacks.onSuccess(response))).pipe(
      concatMap(() => this.placeOrder(cartId))
    );
  } else if (
    callbacks?.onCancel &&
    response.status === OpfPaymentSubmitStatus.CANCELLED
  ) {
    return from(Promise.resolve(callbacks.onCancel(response))).pipe(
```

```
      concatMap(() => EMPTY)
    );
  } else if (response.status === OpfPaymentSubmitStatus.PENDING) {
    return from(Promise.resolve(callbacks.onPending(response))).pipe(
      concatMap(() => EMPTY)
    );
```

Il contenitore globale per gli script del PSP — integration-libs/opf/global-functions/core/facade/opf-global-functions.service.ts:L73-L88:

```ts
protected getContainer(
  domain: OpfGlobalFunctionsDomain
): OpfPaymentGlobalMethods {
  const window = this.winRef.nativeWindow as any;
  if (!window) {
    return {};
  }

  if (!window.Opf?.payments?.[domain]) {
    window.Opf = window?.Opf ?? {};
    window.Opf.payments = window.Opf.payments ?? {};
    window.Opf.payments[domain] = {};
  }

  return window.Opf.payments[domain];
}
```

Route di verifica senza path e location initializer — integration-libs/opf/payment/root/opf-payment-root.module.ts:L21-L46:

```ts
  RouterModule.forChild([
    {
      // @ts-ignore
      path: null,
      component: OpfPaymentVerificationComponent,
      data: {
        cxRoute: 'paymentVerificationResult',
      },
    },
    // ...
  ]),
],
providers: [
  provideDefaultConfig(defaultOpfPaymentRoutingConfig),
  provideLocationInitializerFactory(() => {
    // convert incorrect type `() => void` to `() => Promise<void>`
    const locationInitializer = captureOpfPaymentVerificationQueryFactory();
```

```
      return () => Promise.resolve(locationInitializer());
    }),
  ],
```

Esecuzione di script PSP fuori dalla zone — integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L237-L259:

```ts
  this.ngZone.runOutsideAngular(() => {
    if (this.windowRef.isBrowser() && this.windowRef.nativeWindow) {
      const nativeWindow = this.windowRef.nativeWindow as any;
      if (nativeWindow.OpfContext) {
        delete nativeWindow.OpfContext;
      }

      nativeWindow.OpfContext = contextData ?? {};
      nativeWindow.OpfContext.additionalData ??= {};
    }

    const scriptElement = this.document.createElement('script');
    scriptElement.type = 'text/javascript';
    scriptElement.textContent = originalScript;
    scriptElement.setAttribute('data-opf-script', 'true');
    this.document.head.appendChild(scriptElement);

    // Clean up after execution
    setTimeout(() => {
      if (scriptElement.parentNode) {
        scriptElement.parentNode.removeChild(scriptElement);
      }
    }, 100);
```

Multi-provider della gift card — integration-libs/opf/gift-card/root/opf-gift-card-root.module.ts:L46-L61:

```ts
providers: [
  {
    provide: ORDER_NORMALIZER,
    useExisting: OpfGiftCardOrderOccNormalizer,
    multi: true,
  },
  {
    provide: CART_NORMALIZER,
    useExisting: OpfGiftCardCartOccNormalizer,
    multi: true,
  },
  {
    provide: HTTP_INTERCEPTORS,
```

```
      useClass: OpfGiftCardPaymentApiInterceptor,
      multi: true,
    },
```

Digital Payments: override CMS con `withConfig` — integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.module.ts:L32-L45:

```ts
    ConfigModule.withConfig({
      cmsComponents: {
        CheckoutPaymentDetails: {
          component: DpPaymentMethodComponent,
        },
      },
    }),
    FeaturesConfigModule,
    DpPaymentMethodComponent,
  ],
  exports: [DpPaymentMethodComponent],
  providers: [provideDefaultConfig(defaultDigitalPaymentsConfig)],
})
export class DpPaymentMethodModule extends CorePaymentMethodModule {}
```

OPPS: interceptor del coupon — integration-libs/opps/root/coupon-codes/http-interceptors/occ-opps-coupon-codes.interceptor.ts:L28-L38 e :L51-L63:

```ts
  constructor() {
    this.initialize();
  }

  protected initialize() {
    this.oppsCoupon = this.service.getCouponCodes();
    if (this.winRef.isBrowser()) {
      this.requestHeader =
        this.config.opps?.couponcodes?.httpHeaderName?.toLowerCase?.();
    }
  }
  // ...
    if (
      this.winRef.isBrowser() &&
      this.requestHeader &&
      this.oppsCoupon &&
      request.url.includes(this.occEndpoints.getBaseUrl())
    ) {
      request = request.clone({
        setHeaders: {
          [this.requestHeader]: this.oppsCoupon,
```

```
        },
      });
    }
```

---

7. Commenti e note notevoli dal sorgente

- **"SSR mode not supported for security concerns"** — ripetuto in `executeScriptFromHtml` e `loadResources` (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L175-L175, integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L403-L403). Il codice del PSP non gira mai lato server.
- **Persistenza della sessione solo per 3DS**: "Persist session ID only for 3DS redirect — it must survive the PSP page reload. For other patterns, keeping it in-memory only prevents stale sessions from being reused after a page refresh." (integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L73-L74).
- **"Stores the redirect query string before OAuth bootstrap mutates `location.search`."** — motivo del location initializer di payment (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L71-L73).
- **Location initializer**: "convert incorrect type `() => void` to `() => Promise<void>`", identico in OPF e OPPS (integration-libs/opf/payment/root/opf-payment-root.module.ts:L43-L43, integration-libs/opps/root/coupon-codes/opps-coupon-codes.module.ts:L23-L23).
- **Saferpay e iframe**: "Some PSPs render verification/success pages inside an iframe; in such cases we reload the current URL in the top window to preserve full-page UX." con link alla documentazione Saferpay (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.component.ts:L85-L91).
- **Retry su OTP**: "It means that `accessCode` (OTP signature) is not valid or expired and we need to refresh it." (integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L116-L119).
- `cartId` **deprecato**: "@deprecated Property no longer used. Cart ID is currently derived from the OTP access code header." (integration-libs/opf/global-functions/core/services/opf-global-functions-

shared.service.ts:L46-L46; anche integration-libs/opf/payment/root/model/opf-payment.model.ts:L26-L27).

- **Precedenza** `dynamicScript`: "if `dynamicScript` and `destination` are present in same config, dynamicScript takes precendence." (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L275-L283).
- **JSDoc contraddittorio** di `loadResources`: "The returned Promise is also resolved (not rejected!) immediately when any loading error occurs." (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L395-L395) — vedi §9.
- **TODO tokenisation**: "TO DO: Unify this adapter with Core once Core fixes the paymentDetail PATCH request payload handling." (integration-libs/opf/tokenisation/root/adapters/occ-opf-tokenisation-user-payment.adapter.ts:L67-L67); e i segnaposto "Currently unused as all payment operations are delegated to the core UserPaymentService" (integration-libs/opf/tokenisation/core/connectors/opf-tokenisation.adapter.ts:L9-L16).
- **Workaround CTA**: "Removing script tags on FE until BE fix: CXSPA-8572" (integration-libs/opf/cta/components/opf-cta-element/opf-cta-element.component.ts:L43-L43).
- **Commento sul carrello quick buy**: "`createCart` initially replays the previously created (NEW_CREATED) cart from the store. Skip it so we operate on the freshly created..." (integration-libs/opf/quick-buy/core/services/context/opf-quick-buy-single-product-transaction.service.ts:L307-L341).
- **Deprecazione in B2C**: `@deprecated since 221121.21. No longer used internally.` su `opfBaseFacade` di `OpfCheckoutPaymentAndReviewComponent` (integration-libs/opf/checkout/components/opf-checkout-payment-and-review/opf-checkout-payment-and-review.component.ts:L82-L86).
- **Digital Payments**: `// TODO:#checkout - handle breaking changes` (integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.component.ts:L70-L70).
- `BEFORE_CMS_PAGE_GUARD`: "**CAUTION**: Suitable for global guards ONLY!" (core-libs/storefront/cms-structure/guards/before-cms-page-guard.token.ts:L10-L21) — OPPS lo usa correttamente per un controllo globale.

8. Extension point

8.1 Override via DI fatti da OPF (e da imitare)

TOKEN SOSTITUITO	CON	TIPO PROVIDER	SCOPE	DOVE
`GlobalMessageService` (core)	`OpfGlobalMessageService`	`useExisting`	root (eager)	integration-libs/opf/base/root/opf-base-root.module.ts:L25-L28
`CheckoutAuthGuard` (checkout)	`OpfCheckoutAuthGuard`	`useClass`	root (eager)	integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L44-L47
`CheckoutB2BStepsSetGuard` (checkout b2b)	`OpfB2bCheckoutStepsSetGuard`	`useClass`	root (eager)	integration-libs/opf/b2b-checkout/root/opf-b2b-checkout-root.module.ts:L39-L42

TOKEN SOSTITUITO	CON	TIPO PROVIDER	SCOPE	DOVE
`CheckoutPaymentTypeFacade` (checkout b2b)	`OpfB2bCheckoutPaymentTypeService`	`useExisting`	modulo lazy OPF B2B	`integration-libs/opf/b2b-checkout/core/facade/facade-providers.ts:L11-L17`
`UserPaymentAdapter` (core)	`OccOpfTokenisationUserPaymentAdapter`	`useClass`	root (eager)	`integration-libs/opf/tokenisation/root/opf-tokenisation-root.module.ts:L37-L40`
`ORDER_NORMALIZER`, `CART_NORMALIZER`, `HTTP_INTERCEPTORS`	normalizer/interceptor gift card	`multi: true`	root (eager)	`integration-libs/opf/gift-card/root/opf-gift-card-root.module.ts:L46-L61`
`ORDER_NORMALIZER`	`OpfOccOrderNormalizer`	`multi: true`	chunk order	`integration-libs/opf/order/opf-order.module.ts:L11-L20`
`OpfQuickBuySingleProductCartOptionsFacade`	servizio pickup-in-store	provider	modulo lazy quick buy	`integration-libs/opf/quick-buy/pickup-in-store/opf-quick-buy-pickup-in-store.module.ts:L12-L22`
`cmsComponents.CheckoutPaymentDetails` (DP)	`DpPaymentMethodComponent`	`provideConfig`	chunk checkout	`integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.module.ts:L32-L38`
`HTTP_INTERCEPTORS`, `BEFORE_CMS_PAGE_GUARD` (OPPS)	interceptor coupon, guard login	`multi: true`	root (eager)	`integration-libs/opps/root/coupon-codes/http-interceptors/index.ts:L11-L17`, `integration-libs/opps/root/login-required/opps-login-required.module.ts:L11-L20`

Regola pratica che emerge: OPF mette nel **root module** gli override di guard, adapter di core e interceptor, che così valgono nell'injector root per tutta l'app indipendentemente da quali chunk sono stati caricati; nel **modulo lazy** mette solo gli override consumati dentro lo stesso chunk (con il rischio di scope descritto in §9.17). Per ricette generiche di override di servizi, facade e guard: 50 — Ricette: configurazione, DI, interceptor, eventi.

8.2 Punti di estensione esportati da OPF

PUNTO	TIPO	DOVE	ENTRY POINT
`OpfConfig`, `OpfApiConfig`, `OpfApiEndpoints`	config / augmentation	integration-libs/opf/base/root/config/opf-config.ts:L14-L14, integration-libs/opf/base/root/config/opf-api-config.ts:L15-L17, integration-libs/opf/base/root/model/opf-api-endpoints.model.ts:L7-L7	`@spartacus/opf/base/root` (integration-libs/opf/base/root/public_api.ts:L7-L13)
`OpfBaseFacade`, `OpfBaseAdapter`, `OPF_ACTIVE_CONFIGURATIONS_NORMALIZER`, `OpfEndpointsService`	facade / adapter / token	integration-libs/opf/base/core/connectors/opf-base.adapter.ts:L13-L13, integration-libs/opf/base/core/tokens/tokens.ts:L11-L13	`@spartacus/opf/base/root`, `@spartacus/opf/base/core`
`OpfPaymentFacade`, `OpfPaymentAdapter`, normalizer `OPF_PAYMENT_*`, `OPF_PAYMENT_CONFIG_SERIALIZER`	facade / adapter / token	integration-libs/opf/payment/core/connectors/opf-payment.adapter.ts:L20-L20, integration-libs/opf/payment/core/tokens/tokens.ts:L16-L30, integration-libs/opf/payment/core/connectors/converters.ts:L11-L13	`@spartacus/opf/payment/root` (integration-libs/opf/payment/root/public_api.ts:L7-L13), `/core`

`OpfCtaFacade`, `OpfCtaAdapter`, `OPF_CTA_SCRIPTS_NORMALIZER`	facade / adapter / token	integration-libs/opf/cta/root/facade/opf-cta.facade.ts:L26-L26, integration-libs/opf/cta/core/connectors/opf-cta.adapter.ts:L13-L13	`@spartacus/opf/cta/root`, `/core`
`OpfGlobalFunctionsFacade`, `window.Opf.payments[domain]`	facade / API JS	integration-libs/opf/global-functions/root/facade/opf-global-functions.facade.ts:L24-L24	`@spartacus/opf/global-functions/root` (integration-libs/opf/global-functions/root/public_api.ts:L7-L11)
`OpfQuickBuyConfig`, `OpfQuickBuySingleProductCartOptionsFacade`, `OpfQuickBuyCartAdapter`	config / facade / adapter	integration-libs/opf/quick-buy/root/config/opf-quick-buy-config.ts:L18-L18, integration-libs/opf/quick-buy/root/facade/opf-quick-buy-single-product-cart-options.facade.ts:L22-L22, integration-libs/opf/quick-buy/core/connectors/opf-quick-buy-cart.adapter.ts:L11-L11	`@spartacus/opf/quick-buy/root`, `/core`, `/pickup-in-store`
`LAUNCH_CALLER.OPF_ERROR`	enum augmentation + assegnazione runtime	integration-libs/opf/base/root/model/augmented-core.model.ts:L9-L15	`@spartacus/opf/base/root`

PUNTO	TIPO	DOVE	ENTRY POINT
`DigitalPaymentsModule`, `DpCheckoutModule`, `DpCheckoutPaymentService`	modulo / facade	`integration-libs/digital-payments/public_api.ts:L10-L11`, `integration-libs/digital-payments/src/checkout/index.ts:L7-L9`, `integration-libs/digital-payments/src/checkout/facade/index.ts:L7-L7`	`@spartacus/digital-payments` (adapter, token e config **non** sono esportati da quel barrel)
`OppsConfig`, `OccOppsCouponCodesInterceptor`, `OppsLoginRequiredGuard`	config / interceptor / guard	`integration-libs/opps/root/public_api.ts:L7-L10`	`@spartacus/opps/root`

8.3 Come estendere (con le ricette di Parte III)

- **Aggiungere un endpoint OPF API o cambiarne il path**: estendere `OpfApiEndpoints` per augmentation (come `integration-libs/opf/base/opf-api/model/opf-api-base-endpoints.model.ts:L9-L16`) e fornire `backend.opfApi.endpoints` con `provideConfig`; costruire l'URL con `OpfEndpointsService.buildUrl`. Il pattern è quello di OCC: 52 — Ricette: OCC, adapter, converter, endpoint.
- **Trasformare le risposte OPF**: i token `OPF_*_NORMALIZER` non hanno converter di default, quindi un normalizer aggiunto con `multi: true` è l'unico a operare (`core-libs/core/src/util/converter.service.ts:L106-L111`). Vedi 52.
- **Sostituire un componente OPF** (es. `OpfCheckoutPaymentAndReview`) o aggiungere contenuto negli outlet `OpfCheckoutOutlets`: 51 — Ricette: componenti CMS, outlet, route e layout. Esempio reale: la tokenisation usa `provideOutlet` su `OPF_CHECKOUT_BEFORE_PAYMENT_OPTIONS` (`integration-libs/opf/tokenisation/root/opf-tokenisation-root.module.ts:L41-L55`).
- **Flow di checkout per payment provider**: definire `checkout.flows[<paymentProvider>]` (con l'intera lista di step, perché gli array si sostituiscono): 53 — Ricette: feature lib lazy, carrello/checkout.
- **Override di facade/guard/adapter**: 50 — Ricette: configurazione, DI, interceptor, eventi.
- **Importare solo dagli entry point pubblici** (`@spartacus/opf/<feature>/root|core|...`) e non da path interni: 54 — API pubblica vs interna, upgrade.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. `GlobalMessageService` **cambia per tutta l'app.** Importare `OpfBaseRootModule` sostituisce il servizio globale con la sottoclasse OPF, che può silenziare chiavi per 2 s (`integration-libs/opf/base/root/opf-base-root.module.ts:L25-L28`, `integration-libs/opf/base/root/services/opf-global-message.service.ts:L51-L60`). Un vostro override di `GlobalMessageService` entra in conflitto con questo.
2. **Due default per** `checkout.flows.OPF`. B2C e B2B root module forniscono entrambi il flow come default; con entrambi importati (come nell'app) bisogna scegliere esplicitamente con `provideConfig` (`integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L56-L56`, `integration-libs/opf/b2b-checkout/root/opf-b2b-checkout-root.module.ts:L43-L43`, `projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L73-L81`).
3. **Il flow dipende dal backend.** Il flow `OPF` si attiva solo se `baseStore.paymentProvider === 'OPF'`, letto una volta con `take(1)` (`feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L20-L44`). `BaseSiteService.get()` non emette prima del caricamento dei base site: passa da `getActive()`, che filtra i valori falsy, e da `getAll()`, che filtra `null` e lancia `LoadBaseSites` (`core-libs/core/src/site-context/facade/base-site.service.ts:L31-L35`, `core-libs/core/src/site-context/`

facade/base-site.service.ts:L41-L50, core-libs/core/src/site-context/facade/base-site.service.ts:L63-L69). Il nome resta `undefined` solo se il base site caricato non contiene `baseStore.paymentProvider`.

4. **URL con `undefined`.** `_activeBaseSite` è riempito in modo asincrono: un `buildUrl` chiamato prima della prima emissione produce `.../undefined/...` (integration-libs/opf/base/core/services/opf-endpoints.service.ts:L26-L38, integration-libs/opf/base/core/services/opf-endpoints.service.ts:L74-L74).
5. **Endpoint come oggetto.** `getEndpointFromContext` restituisce il valore di config così com'è e `buildUrl` lo tratta come stringa (`opfEndpoint.includes('?')`): un `OpfApiEndpoint` oggetto, ammesso dal tipo, non viene risolto (integration-libs/opf/base/core/services/opf-endpoints.service.ts:L53-L53, integration-libs/opf/base/core/services/opf-endpoints.service.ts:L77-L88, integration-libs/opf/base/root/model/opf-api-endpoint.model.ts:L7-L10).
6. **Header di lingua congelati.** `OpfApiBaseAdapter` e `OpfApiCtaAdapter` calcolano `Accept-Language` una volta, come campi; `OpfApiQuickBuyAdapter` fa lo stesso con `Content-Language`; `OpfApiPaymentAdapter` usa getter (integration-libs/opf/base/opf-api/adapters/opf-api-base.adapter.ts:L53-L63, integration-libs/opf/cta/opf-api/adapters/opf-api-cta.adapter.ts:L50-L54, integration-libs/opf/quick-buy/opf-api/adapters/opf-api-quick-buy.adapter.ts:L49-L53, integration-libs/opf/payment/opf-api/adapters/opf-api-payment.adapter.ts:L62-L83).
7. **Nessuna cache delle active configurations.** Ogni chiamata a `getActiveConfigurationsState` crea una nuova Query (integration-libs/opf/base/core/facade/opf-base.service.ts:L23-L34); inoltre `OpfCheckoutPaymentsComponent` filtra **in place** `state.data.value` (integration-libs/opf/checkout/components/opf-checkout-payments/opf-checkout-payments.component.ts:L219-L228).
8. `CANCELLED` **senza** `onCancel` **diventa "status non riconosciuto".** Il ramo cancel richiede `callbacks?.onCancel`; senza, uno status `CANCELLED` cade nel ramo finale con `STATUS_NOT_RECOGNIZED` (integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L197-L226). Le global functions `submit`/`submitComplete` forniscono un `submitCancel` di default (integration-libs/opf/global-functions/core/services/opf-global-functions-shared.service.ts:L121-L148), ma il ritorno 3DS e Google Pay quick buy chiamano la facade senza `onCancel`, quindi per loro un `CANCELLED` diventa `STATUS_NOT_RECOGNIZED` (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L390-L400, integration-libs/opf/quick-buy/components/opf-quick-buy-buttons/google-pay/google-pay.service.ts:L34-L38, integration-libs/opf/quick-buy/components/opf-quick-buy-buttons/google-pay/google-pay.service.ts:L506-L513). Lo stesso vale per chi chiama `OpfPaymentFacade.submitPayment` direttamente.
9. **Il retry su 401 del wrapper non scatta.** In `initiatePayment` il `catchError(handlePaymentInitiationError)` precede il `backOff`; per un 401 restituisce `throwError(() => 'Payment failed')`, una stringa, mentre `isAuthorizationError` controlla `err.status === 401` (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L179-L188, integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L333-L343, integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L379-L388, core-libs/core/src/util/occ-http-error-handlers.ts:L26-L28). Nel submit hosted fields invece l'errore originale viene rilanciato, il retry funziona, ma `handlePaymentError` viene invocato a ogni tentativo (integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L107-L122).
10. **409 non gestito se il place order fallisce.** In `handlePaymentAlreadyDoneError`, se il place order fallisce `catchError` restituisce `of()`, che completa senza emettere: lo `switchMap` successivo non parte (integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L345-L359).
11. **Verifica che parte "carrello non trovato".** Senza il toggle, `checkIfProcessingCartIdExist` è chiamato subito: se `isPaymentInProgress === false` (ad esempio perché il metadata è stato azzerato) si va al carrello

con errore anche se la verifica riuscirebbe (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.component.ts:L45-L50, integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L266-L283).

12. **La sessione non sopravvive al refresh** (salvo 3DS): è un comportamento voluto (§7), ma significa che con `opfCheckoutUseUpdatePaymentTransaction` dopo un reload si torna a `initiatePayment` (integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L62-L83, integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L239-L255).
13. **CSP.** `executeScriptFromHtml` usa `Function()` (equivalente a eval) e i template usano `bypassSecurityTrustHtml`/`bypassSecurityTrustResourceUrl`: una Content Security Policy restrittiva rompe i PSP (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L182-L182, integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.component.ts:L103-L109).
14. `loadResources` **rifiuta, nonostante il JSDoc.** Il commento dice che la Promise è risolta anche in errore, ma `loadScript`/`loadStyles` chiamano `reject()` e `Promise.all` rifiuta; i chiamanti infatti hanno `.catch` (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L395-L395, integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L141-L142, integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L429-L435).
15. **Risorse locali e CSS** `SEPARATE`**.** Con `localPspResources` configurato per quell'opzione, il CSS `SEPARATE` aggiunto a `styles` viene ignorato perché le risorse locali sostituiscono quelle esterne (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L408-L416).
16. `OPF_ERROR` **configurato due volte**, `inline` nel modulo error modal e `inlineRoot` nel core delle global functions, entrambi come default (integration-libs/opf/base/components/opf-error-modal/default-opf-error-modal.layout.config.ts:L10-L18, integration-libs/opf/global-functions/core/config/default-opf-global-layout.config.ts:L14-L27). DA VERIFICARE quale prevale: dipende dall'ordine con cui i due moduli lazy vengono caricati e i default fusi.
17. **Override con scope lazy.** `CheckoutPaymentTypeFacade` è rilegata solo nel modulo lazy OPF B2B, mentre la facade standard è una `facadeFactory` di `CHECKOUT_CORE_FEATURE`; consumatori fuori da quell'injector (es. il guard root `OpfB2bCheckoutStepsSetGuard`) potrebbero ricevere l'implementazione standard (integration-libs/opf/b2b-checkout/core/facade/facade-providers.ts:L11-L17, feature-libs/checkout/b2b/root/facade/checkout-payment-type.facade.ts:L17-L18, integration-libs/opf/b2b-checkout/root/guards/opf-b2b-checkout-steps-set.guard.ts:L39-L56). DA VERIFICARE a runtime (risoluzione proxy vs injector lazy). Inoltre `getPaymentTypesState()` restituisce `of()` e `getPaymentTypes()` non emette mai (integration-libs/opf/b2b-checkout/core/facade/opf-b2b-checkout-payment-type.service.ts:L103-L109).
18. **Il B2C OPF dipende dal pacchetto checkout B2B**: `OpfCheckoutPaymentAndReviewComponent` inietta `CheckoutPaymentTypeFacade` di `@spartacus/checkout/b2b/root` (integration-libs/opf/checkout/components/opf-checkout-payment-and-review/opf-checkout-payment-and-review.component.ts:L23-L23, integration-libs/opf/checkout/components/opf-checkout-payment-and-review/opf-checkout-payment-and-review.component.ts:L81-L81).
19. **T&C esplicito per sottostringa**: `JSON.stringify(page).includes(uid)` attiva il T&C con qualunque occorrenza della stringa nella pagina (integration-libs/opf/checkout/components/opf-checkout-payment-and-review/opf-checkout-payment-and-review.component.ts:L129-L131).
20. **Moduli lazy che reimportano il root.** `OpfGiftCardModule` e `OpfTokenisationModule` reimportano i rispettivi root module: interceptor, normalizer e override vengono registrati anche nell'injector lazy (integration-libs/opf/gift-card/opf-gift-card.module.ts:L13-L21, integration-libs/opf/tokenisation/opf-tokenisation.module.ts:L11-L18). DA VERIFICARE l'effetto della doppia registrazione degli `HTTP_INTERCEPTORS` (l'`HttpClient` root dovrebbe usare quelli root, non confermato a runtime).

21. **Interceptor gift card su ogni errore di place order**: ricarica il carrello per qualunque errore di `paymentAuthorizedOrderPlacement`, non solo gift card, ed è registrato eager anche quando la gift card non è configurata (integration-libs/opf/gift-card/root/http-interceptors/opf-gift-card-payment-api.interceptor.ts:L43-L50, projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L85-L103).
22. **Doppio slash corretto a posteriori**: con `paymentSessionId` vuoto (quick buy) il path diventa `payments//submit`, poi corretto con `.replace('//submit', '/submit')` (integration-libs/opf/payment/opf-api/adapters/opf-api-payment.adapter.ts:L264-L270).
23. **Stato condiviso nel quick buy.** `OpfQuickBuyTransactionService` memorizza `transactionContext` e non lo azzera (integration-libs/opf/quick-buy/core/services/opf-quick-buy-transaction.service.ts:L34-L47, integration-libs/opf/quick-buy/core/services/opf-quick-buy-transaction.service.ts:L173-L179); `OpfDynamicCtaService` è condiviso tra CTA scripts e CTA quick buy nello stesso injector lazy: è `@Injectable()` senza `providedIn` ed è fornito da due NgModule importati entrambi da `OpfCtaComponentsModule`, quindi finisce in un unico module injector (integration-libs/opf/cta/core/services/opf-dynamic-cta.service.ts:L46-L47, integration-libs/opf/cta/components/opf-cta-scripts/opf-cta-scripts.module.ts:L20-L22, integration-libs/opf/cta/components/opf-cta-quick-buy-buttons/opf-cta-quick-buy-buttons.module.ts:L19-L21, integration-libs/opf/cta/components/opf-cta-components.module.ts:L13-L16); lo stato interno condiviso è in integration-libs/opf/cta/core/services/opf-dynamic-cta.service.ts:L57-L60.
24. **Digital Payments richiede il chunk del checkout.** `DpPaymentMethodComponent` inietta le classi concrete `CheckoutDeliveryAddressService`/`CheckoutPaymentService` di `checkout/base/core`, non le facade: funziona solo nello stesso injector lazy del checkout core, come in `CheckoutWrapperModule` (integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.component.ts:L15-L18, integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.component.ts:L71-L80). E `defaultDigitalPaymentsConfig` è fornito dal modulo CMS, non da `DpCheckoutModule`: senza di esso `sid`/`sign` non vengono aggiunti (integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.module.ts:L43-L43, integration-libs/digital-payments/src/checkout/adapters/occ-digital-payments.adapter.ts:L86-L95).
25. `getCardRegistrationDetails` **lancia dentro** `map` se la query è in errore, rompendo lo stream (integration-libs/digital-payments/src/checkout/facade/dp-checkout-payment.service.ts:L44-L54).
26. **OPPS legge il coupon una sola volta.** L'interceptor lo legge nel costruttore: un coupon salvato dopo l'istanziazione non viene inviato fino a nuova istanza (integration-libs/opps/root/coupon-codes/http-interceptors/occ-opps-coupon-codes.interceptor.ts:L28-L38). `DA VERIFICARE` l'ordine reale tra il location initializer e la prima istanza dell'interceptor (richiede esecuzione). Inoltre, con un URL senza `?`, `url.substring(url.indexOf('?'))` passa l'URL intero a `URLSearchParams` e il coupon risulta `null` (integration-libs/opps/root/coupon-codes/opps-coupon-codes.service.ts:L18-L26).

---

10. Come fare debug

- **La feature OPF non si carica / "Feature ... is not configured properly".** Il proxy `facadeFactory` richiede che la feature sia in `featureModules` (core-libs/core/src/lazy-loading/facade-factory/facade-factory.ts:L10-L23): controllare la mappa nell'app (projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L105-L152) e il nome della feature nella facade (es. `OPF_BASE_FEATURE`, integration-libs/opf/base/root/facade/opf-base.facade.ts:L21-L21).

- **Il checkout non usa gli step OPF.** Controllare `baseSite.baseStore.paymentProvider` (deve essere `OPF`) e che `checkout.flows.OPF` sia quello atteso (B2C/B2B) (feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L28-L44, projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L73-L81).
- **Network.** Le chiamate OPF vanno a `${opfBaseUrl}/${baseSite}/...` (§3.2); verificare gli header `sap-commerce-cloud-public-key` e `sap-commerce-cloud-access-code` (integration-libs/opf/base/root/config/constants.ts:L7-L8). Un `.../undefined/...` nell'URL indica il problema di §9.4. Un 401 su submit indica OTP scaduto (retry automatico, §3.7).
- **Stato OPF.** Non c'è NgRx: in DevTools ispezionare in `localStorage` la chiave `spartacus⚿⚿opf` (default di `StatePersistenceService`: `storageType = LOCAL_STORAGE`, `context$ = of('')`, prefisso `spartacus⚿<context>⚿`; OPF passa solo `key`, `state$` e `onRead`) (integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L34-L47, integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L41-L45, core-libs/core/src/state/services/state-persistence.service.ts:L44-L48, core-libs/core/src/state/services/state-persistence.service.ts:L124-L130) e, durante il ritorno dal PSP, `sessionStorage['opfPaymentVerificationQuerySearch']` (integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L40-L41). Vedi anche 19.
- **Script PSP.** In console: `window.Opf.payments` mostra i domini registrati (integration-libs/opf/global-functions/core/facade/opf-global-functions.service.ts:L81-L87); `window.OpfContext` il contesto della modalità `SEPARATE` (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L244-L245); `document.querySelectorAll('[data-opf-resource]')` le risorse caricate (integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L186-L194). In SSR nulla di tutto questo esiste (§7).
- **Messaggi globali che "spariscono".** Possono essere stati silenziati da `OpfGlobalMessageService.disableGlobalMessage` (integration-libs/opf/base/root/services/opf-global-message.service.ts:L51-L60).
- **Ritorno dal PSP che finisce sul carrello.** Verificare il toggle `opfPaymentVerificationCheckProcessingCartOnErrorOnly` e `isPaymentInProgress` (§9.11).
- **OPPS.** Verificare in `localStorage` la chiave `opps-couponcodes` e l'header `couponcodes` sulle richieste OCC (integration-libs/opps/root/config/default-opps-config.ts:L11-L15).
- **Test.** OPF ha un `karma.conf.js` e un `test.ts` (Jasmine) (integration-libs/opf/test.ts), mentre digital-payments e opps hanno `vitest.config.ts` (integration-libs/digital-payments/vitest.config.ts, integration-libs/opps/vitest.config.ts). Comandi da `.claude/CLAUDE.md`: `nx run <library-name>:test` (Jasmine) e `nx test-vitest <library-name>`. I nomi dei progetti Nx sono `opf` (target `test`, Jasmine), `digital-payments` e `opps` (target `test-vitest`) (integration-libs/opf/project.json:L2-L2, integration-libs/opf/project.json:L20-L20, integration-libs/digital-payments/project.json:L2-L2, integration-libs/digital-payments/project.json:L20-L20, integration-libs/opps/project.json:L2-L2, integration-libs/opps/project.json:L23-L23): quindi `nx run opf:test`, `nx test-vitest digital-payments`, `nx test-vitest opps`.

---

11. Domande di autoverifica

1. **Perché il `public_api.ts` di `@spartacus/opf` è vuoto e come si importano i simboli?** Perché ogni sotto-feature ha i propri secondary entry point (`@spartacus/opf/base/root`, `/payment/root`, ...); il barrel radice esporta solo `{}`. — integration-libs/opf/public_api.ts:L14-L16, projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L105-L152

2. **Come fa il checkout standard a usare gli step OPF senza che OPF modifichi** `checkout.steps`**?** `CheckoutFlowOrchestratorService` sceglie `checkout.flows[paymentProvider]` in base al base store; OPF fornisce `checkout.flows.OPF` e forza l'istanziazione dell'orchestratore con un app initializer. — feature-libs/checkout/base/components/services/checkout-flow-orchestrator.service.ts:L20-L44, integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L58-L60, integration-libs/opf/checkout/root/config/default-opf-checkout-config.ts:L36-L45
3. **Perché l'app usa** `provideConfig` **per il flow OPF anziché affidarsi ai default?** Perché B2C e B2B root module forniscono entrambi un default per `checkout.flows.OPF` e gli array di step si sostituiscono nel merge. — integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L56-L56, integration-libs/opf/b2b-checkout/root/opf-b2b-checkout-root.module.ts:L43-L43, core-libs/core/src/config/utils/deep-merge.ts:L31-L46, projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L73-L81
4. **Quali sono i tre render pattern e come vengono resi?** `IFRAME` (iframe con sandbox configurabile), `FULL_PAGE` (link o form `_self`), `HOSTED_FIELDS` (script/HTML del PSP + global functions). `dynamicScript` ha la precedenza su `destination`. — integration-libs/opf/payment/root/model/opf-payment.model.ts:L250-L254, integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.component.html:L15-L69, integration-libs/opf/checkout/components/opf-checkout-payment-wrapper/opf-checkout-payment-wrapper.service.ts:L275-L331
5. **Perché esiste un location initializer in** `OpfPaymentRootModule`**?** Per salvare in `sessionStorage` la query string del redirect del PSP prima che il bootstrap OAuth modifichi `location.search`. — integration-libs/opf/payment/root/opf-payment-root.module.ts:L42-L46, integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.service.ts:L71-L98
6. **Come sopravvive la sessione di pagamento al redirect 3DS se non viene persistita normalmente?** `handle3DSRedirect` imposta `is3DSRedirect: true`; la persistenza include `opfPaymentSessionId` solo in quel caso; al reload `initSync` ripristina lo stato e la pagina di verifica esegue `run3DSRedirectPattern`. — integration-libs/opf/global-functions/core/services/domains/checkout/opf-global-functions-checkout-domain.service.ts:L91-L118, integration-libs/opf/base/root/services/opf-metadata-state-persistence.service.ts:L62-L83, integration-libs/opf/payment/root/components/opf-payment-verification/opf-payment-verification.component.ts:L114-L122
7. **Cosa succede se il servizio OPF risponde 401 a un submit hosted fields?** Il `backOff` con `isAuthorizationError` ripete l'intera sequenza, ottenendo un nuovo OTP, fino a `DEFAULT_AUTHORIZATION_ERROR_RETRIES_COUNT` volte. — integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L115-L122, core-libs/core/src/util/occ-http-error-handlers.ts:L26-L31, core-libs/core/src/util/rxjs/back-off.ts:L39-L61
8. **Dove viene sostituito** `CheckoutAuthGuard` **e con quale effetto?** Nel root module eager `OpfCheckoutRootModule`, con `useClass: OpfCheckoutAuthGuard`: l'override vale nell'injector root, quindi per ogni componente CMS che dichiara `CheckoutAuthGuard` (incluso `OpfCheckoutPaymentAndReview`), a differenza dell'override lazy di `CheckoutPaymentTypeFacade` (§9.17). — integration-libs/opf/checkout/root/opf-checkout-root.module.ts:L44-L47, integration-libs/opf/checkout/components/opf-checkout-payment-and-review/opf-checkout-payment-and-review.module.ts:L57-L66, integration-libs/opf/b2b-checkout/core/facade/facade-providers.ts:L11-L17
9. **Perché il codice del PSP non viene mai eseguito in SSR?** `loadResources` ed `executeScriptFromHtml` controllano `isPlatformServer` ("SSR mode not supported for security concerns"); anche la registrazione delle global functions è solo browser. — integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L174-L184, integration-libs/opf/base/root/services/opf-resource-loader.service.ts:L397-L406, integration-libs/opf/global-functions/core/facade/opf-global-functions.service.ts:L38-L41

10. **Come si aggiunge Digital Payments al checkout e cosa cambia nel CMS?** L'app importa `DigitalPaymentsModule` nel chunk del checkout; `DpPaymentMethodModule` sostituisce il componente `CheckoutPaymentDetails` con `provideConfig` (via `ConfigModule.withConfig`). — projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts:L22-L33, integration-libs/digital-payments/src/checkout/cms-components/dp-payment-method/dp-payment-method.module.ts:L32-L38, core-libs/core/src/config/config.module.ts:L28-L34
11. **Come fa OPPS a imporre il login prima di una pagina CMS?** Registra `OppsLoginRequiredGuard` nel multi-token `BEFORE_CMS_PAGE_GUARD`; per utenti anonimi con `?loginRequired=true` salva l'URL di redirect e restituisce l'`UrlTree` della pagina di login. — integration-libs/opps/root/login-required/opps-login-required.module.ts:L11-L20, integration-libs/opps/root/login-required/opps-login-required.guard.ts:L29-L61

TAVOLA 35.1 **4.1 Checkout OPF: dalla lista opzioni al rendering del PSP**

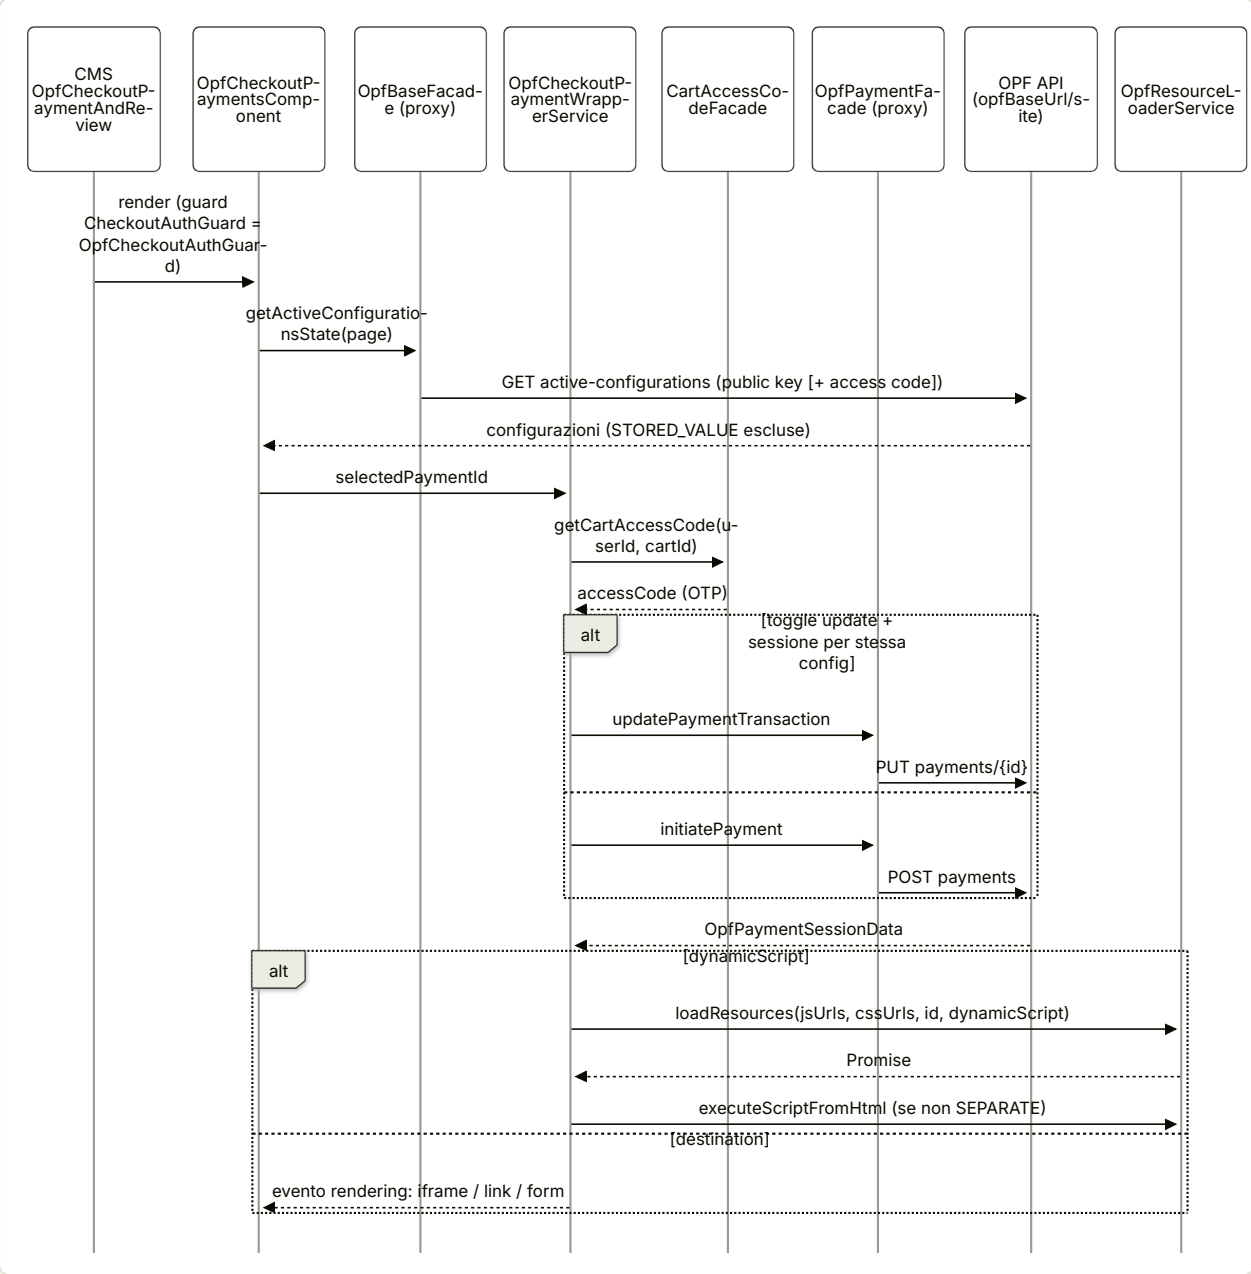

TAVOLA 35.2 **4.2 Ritorno dal PSP: scelta del pattern**

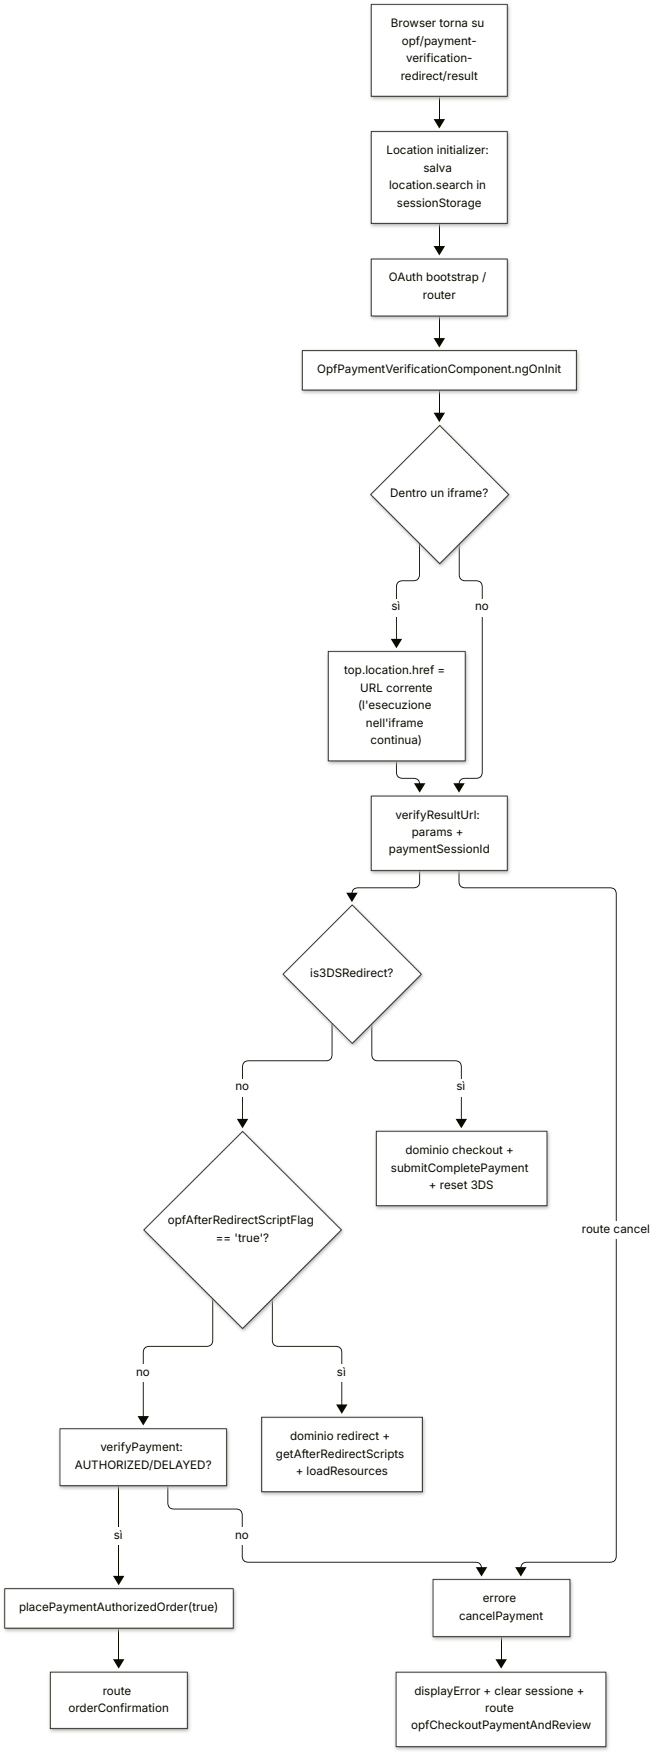

TAVOLA 35.3 **4.3 Hosted fields e 3DS: lo script PSP pilota Spartacus**

1. A cosa serve e perché esiste

Sotto `integration-libs/` vivono librerie che funzionano solo con un backend Commerce arricchito da addon o da sistemi esterni SAP. Questo capitolo ne copre sei:

LIBRERIA	PACCHETTO	COSA AGGIUNGE ALLO STOREFRONT
S/4HANA Service	`@spartacus/s4-service`	prodotti di tipo *servizio*: step di checkout "service details" (data/ora dell'intervento), cancel e reschedule del servizio dal dettaglio ordine
S/4HANA Order Management	`@spartacus/s4om`	*schedule lines* (date/quantità confermate) sotto ogni riga di carrello; prodotti "non in catalogo" restituiti da S/4
Order Management Foundation	`@spartacus/omf`	dettaglio ordine richiesto con un header `guid` aggiuntivo
CPQ quote	`@spartacus/cpq-quote`	colonna sconti CPQ nella tabella delle righe di carrello/quote
Punchout	`@spartacus/punchout`	sessioni cXML punchout avviate da un sistema di procurement esterno, con navigazione limitata e ritorno della *requisition*
EPD Visualization	`@spartacus/epd-visualization`	*visual picking* 3D/2D dei ricambi tramite SAP EPD e UI5 (libreria **deprecata**)

Le integration libs dichiarano la propria versione `"version": "221121.22.0"`, non la 2612.0.0 delle core libs (integration-libs/omf/package.json:L3-L3).

La ragione per studiarle insieme è architetturale: **quasi nessuna di queste librerie porta una feature "propria"**. Invece di definire un nuovo dominio con store, facade lazy e componenti CMS, le librerie si **innestano** su feature esistenti (order, checkout, cart, auth, product) sostituendo token DI già esistenti con `useClass`/`useExisting`, aggiungendo componenti tramite outlet, estendendo con *module augmentation* modelli e enum del core e, in un caso, sostituendo un intero token di configurazione. Sono quindi il miglior catalogo "dal vero" di come si estende Spartacus via DI, e insieme il miglior catalogo dei rischi di farlo:

- quando il token sostituito è fornito da un modulo del chunk lazy, l'override deve stare **nello stesso injector** del binding originale e **dopo** di esso: per questo l'app demo importa `OmfOrderModule`, `S4ServiceOrderModule` e `S4ServiceCheckoutModule` dentro i *wrapper module* lazy delle feature order/checkout, dopo il modulo feature (projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L14-L27, projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts:L16-L33). Anche `CpqQuoteModule` sta nel wrapper del carrello dopo `CartBaseModule` (projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L14-L25), ma lì è una scelta dell'app demo e degli schematics, non un vincolo DI: il servizio core che sostituisce, `CartItemListComponentService`, esiste solo come `providedIn: 'root'` e nessun modulo del core lo fornisce (feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.service.ts:L9-L16);
- due librerie che sovrascrivono lo stesso token (es. B2B e s4-service su `CheckoutStepsSetGuard`) entrano in competizione e vince l'ultima registrata (feature-libs/checkout/b2b/components/checkout-b2b-components.module.ts:L33-L36, integration-libs/s4-service/checkout/components/s4-service-checkout-component.module.ts:L14-L27);
- il core stesso ha introdotto nuovi extension point (es. `EXPIRED_REFRESH_TOKEN_HANDLERS`) proprio per evitare che due librerie (Punchout e ASM) si contendano `AuthHttpHeaderService` (core-libs/core/src/auth/

user-auth/services/auth-http-header.service.ts:L311-L316).

Prerequisiti: 01 — Dependency Injection (gerarchia degli injector, `useClass`/`useExisting`, multi provider), 12 — Feature module e lazy loading (`featureModules`, `facadeFactory`), 17 — Outlet, 26 — Checkout, 27 — Ordini, 22 — Autenticazione.

---

2. Mappa dei file

Wiring nell'app demo

PATH	RUOLO
`projects/storefrontapp/src/environments/environment.ts`	flag `cpq`, `epdVisualization`, `s4om`, `omf`, `s4Service`, `punchout` da variabili `CX_*` (default `false`)
`projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts`	aggiunge i feature module "root" eager in base ai flag
`projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts`	`OrderModule` + `S4ServiceOrderModule` + `OmfOrderModule` (chunk lazy order)
`projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts`	`CheckoutModule` + B2B + `S4ServiceCheckoutModule`
`projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts`	`CartBaseModule` + `CpqQuoteModule`
`projects/storefrontapp/src/app/spartacus/features/s4-service/s4-service-feature.module.ts`	feature `s4-service` (lazy, modulo vuoto)
`projects/storefrontapp/src/app/spartacus/features/punchout/punchout-feature.module.ts`	loader `import('@spartacus/punchout')`
`projects/storefrontapp/src/app/spartacus/features/epd-visualization/epd-visualization-feature.module.ts`	`apis.baseUrl`, `ui5.bootstrapUrl`
`core-libs/schematics/src/shared/lib-configs/integration-libs/*-schematics-config.ts`	`importAfter` che codifica l'ordine degli import

`@spartacus/omf`

PATH	RUOLO
`integration-libs/omf/root/omf-root.module.ts`	`OmfRootModule` vuoto
`integration-libs/omf/order/omf-order.module.ts`	override DI `OrderHistoryAdapter` + `OrderHistoryFacade`, default config
`integration-libs/omf/order/occ-omf-order-history.adapter.ts`	`OccOmfOrderHistoryAdapter`: header `guid` sul dettaglio ordine
`integration-libs/omf/order/omf-order-history.service.ts`	`OmfOrderHistoryService`: `getQueryParams` → `{ guid }`
`integration-libs/omf/order/config/default-omf-config.ts`	`guidHttpHeaderName: 'guid'`
`integration-libs/omf/order/config/omf-config.ts`	token `OmfConfig`

@spartacus/s4om

PATH	RUOLO
integration-libs/s4om/root/s4om-root.module.ts	outlet ITEM_DETAILS + override ProductCatalogService
integration-libs/s4om/root/services/s4om-product-catalog.service.ts	isProductInCatalog con notOrderable
integration-libs/s4om/root/components/schedule-lines/schedule-lines.component.ts	UI schedule lines
integration-libs/s4om/root/model/augmented-core.model.ts	augmentation OrderEntry.scheduleLines
integration-libs/s4om/s4om.module.ts	entry primario vuoto

@spartacus/cpq-quote

PATH	RUOLO

integration-libs/epd-visualization/styles/components/visual-viewer/visual-viewer-animation-slider.component.scss	Placeholder %cx-epd-visualization-animation-slider (:L1-L73).
integration-libs/epd-visualization/styles/components/visual-viewer/visual-viewer-toolbar-button.component.scss	Placeholder %cx-epd-visualization-viewer-toolbar-button (:L1-L79).
integration-libs/epd-visualization/styles/components/visual-viewer/visual-viewer.component.scss	Placeholder %cx-epd-visualization-viewer (griglia, viewport UI5) (:L1-L155).

3. Come funziona passo per passo

3.1 Il pattern comune: "root eager + estensione nel wrapper lazy"

Ogni libreria è attivata nell'app demo da un flag d'ambiente con default `false` (projects/storefrontapp/src/environments/environment.ts:L30-L43). Quando il flag è attivo, il feature module "root" della libreria entra nei `featureModules` eager di `SpartacusFeaturesModule` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L133-L175).

Le parti che **sovrascrivono** binding di altre feature non sono però caricate come feature lazy proprie:

- `S4ServiceOrderModule` e `OmfOrderModule` sono importati **dopo** `OrderModule` dentro `OrderWrapperModule` (projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L14-L27), che è proprio il modulo caricato lazy dalla feature order (projects/storefrontapp/src/app/spartacus/features/order/order-feature.module.ts:L29-L30);
- `S4ServiceCheckoutModule` è importato in `CheckoutWrapperModule` **dopo** `CheckoutB2BModule` (che entra solo con `environment.b2b`) (projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts:L16-L33);
- `CpqQuoteModule` è importato dopo `CartBaseModule` in `CartBaseWrapperModule` (projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L14-L25).

Il motivo è la gerarchia degli injector (vedi 03 — Lazy loading): i provider di `OrderModule` vivono nell'injector del chunk lazy; un override nell'AppModule sarebbe "più in alto" e quindi oscurato dal binding originale. Nello stesso injector, a parità di token, vince il provider registrato per ultimo, quindi l'ordine `[OrderModule, ...extensions]` è essenziale. DA VERIFICARE a runtime che un override in AppModule venga effettivamente oscurato (deduzione dalla gerarchia degli injector lazy, `node_modules` assente).

Gli schematics codificano lo stesso vincolo con `importAfter` (coppie *marker module* → *feature module*): s4-service va dopo `CHECKOUT_B2B_MODULE` e `ORDER_MODULE` (core-libs/schematics/src/shared/lib-configs/integration-libs/s4-service-schematics-config.ts:L74-L83), `OMF_ORDER_MODULE` dopo `ORDER_MODULE` con dipendenza dalla feature order (core-libs/schematics/src/shared/lib-configs/integration-libs/omf-schematics-config.ts:L29-L50), `CPQ_QUOTE_MODULE` dopo `CART_BASE_MODULE` (core-libs/schematics/src/shared/lib-configs/integration-libs/cpq-quote-schematics-config.ts:L45-L51). Gli schematic `add-*` delle librerie sono tutti uguali: analizzano le dipendenze cross-feature, chiamano `addFeatures` e aggiungono le peer dependencies (integration-libs/s4-service/schematics/add-s4-service/index.ts:L25-L42). Per i dettagli vedi 43 — Schematics e migrazioni.

3.2 OMF: un header `guid` sul dettaglio ordine

`OmfRootModule` è un `@NgModule()` vuoto e la costante `OMF_FEATURE = 'OMF'` non è usata da alcun `featureModules` (integration-libs/omf/root/omf-root.module.ts:L9-L10, integration-libs/omf/root/feature-name.ts:L7-L7). Tutto il lavoro è in `OmfOrderModule`, che sostituisce **due** token della feature order (integration-libs/omf/order/omf-order.module.ts:L15-L26):

- `OrderHistoryAdapter` → `OccOmfOrderHistoryAdapter` (`useClass`), al posto di `OccOrderHistoryAdapter` (feature-libs/order/occ/order-occ.module.ts:L42-L42);
- `OrderHistoryFacade` → `OmfOrderHistoryService` (`useClass`), al posto di `useExisting: OrderHistoryService` (feature-libs/order/core/facade/facade-providers.ts:L33-L37).

Il flusso:

1. Lo storico ordini usa `orderHistoryFacade.getQueryParams(order)` come `queryParams` dei link verso il dettaglio (feature-libs/order/components/order-history/order-history.component.ts:L126-L133). Nel core il metodo restituisce `null` ed è `@deprecated` (feature-libs/order/core/facade/order-history.service.ts:L220-L225).
2. `OmfOrderHistoryService` estende `OrderHistoryService` e sovrascrive solo `getQueryParams`, restituendo `{ guid }` se l'ordine lo possiede (integration-libs/omf/order/omf-order-history.service.ts:L12-L24). Il campo `guid?: string` è già nel modello `Order` del core (feature-libs/order/root/model/order.model.ts:L86-L86).
3. Il dettaglio ordine invoca `OrderHistoryAdapter.load`, che ora è `OccOmfOrderHistoryAdapter.load` (integration-libs/omf/order/occ-omf-order-history.adapter.ts:L69-L86).

4. `getOrderGuid` legge `guid` dai query param della rotta attiva; se manca (caso "My-Account-V2") lo cerca nella lista ordini dello store NgRx tramite `OrderSelectors.getOrdersState` (integration-libs/omf/order/occ-omf-order-history.adapter.ts:L31-L53).
5. `getRequestHeader` mette il guid in un header il cui nome è `omf.guidHttpHeaderName` convertito in minuscolo; se la chiave manca e si è in dev mode logga un warning (integration-libs/omf/order/occ-omf-order-history.adapter.ts:L55-L67). Il default è `'guid'` (integration-libs/omf/order/config/default-omf-config.ts:L9-L13).
6. Per l'utente anonimo aggiunge anche l'header `USE_CLIENT_TOKEN`, poi fa la GET verso `getOrderDetailUrl` e normalizza con `ORDER_NORMALIZER` (integration-libs/omf/order/occ-omf-order-history.adapter.ts:L69-L86). `logger` e `getOrderDetailUrl` sono membri `protected` della superclasse (feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L47-L47, feature-libs/order/occ/adapters/occ-order-history.adapter.ts:L212-L212).

`OmfConfig` è il classico config token astratto risolto `useExisting: Config`, con il tipo `OmfConfiguration` preso dall'entry primario `@spartacus/omf` (integration-libs/omf/order/config/omf-config.ts:L7-L21).

3.3 S/4HANA Order Management: schedule lines e prodotti fuori catalogo

`S4omRootModule` (eager) fa due cose (integration-libs/s4om/root/s4om-root.module.ts:L17-L35):

- registra `ScheduleLinesComponent` nell'outlet `CartOutlets.ITEM_DETAILS` in posizione `AFTER`;
- sostituisce `ProductCatalogService` con `useExisting: S4omProductCatalogService`.

Importa inoltre `RequestedDeliveryDateComponentsModule` e `PDFInvoicesComponentsModule` solo per forzare l'installazione di quelle librerie insieme a S4OM, come dice il commento in linea (integration-libs/s4om/root/s4om-root.module.ts:L18-L22). L'entry primario `S4omModule` è vuoto (integration-libs/s4om/s4om.module.ts:L8-L12).

Prodotti fuori catalogo. Il `ProductCatalogService` core considera "in catalogo" qualunque prodotto non nullo (core-libs/core/src/product/services/product-catalog.service.ts:L20-L22). La versione S4OM ritorna `false` se `stock.stockLevelStatus === 'notOrderable'` (prodotto arrivato da S/4 ma assente in Commerce) e `true` se lo status manca (integration-libs/s4om/root/services/s4om-product-catalog.service.ts:L13-L37). Il metodo è consumato dal carrello (link disabilitato nella lista item, add-to-cart "unavailable") e dall'ordine (reorder) (feature-libs/cart/base/components/cart-shared/cart-item-list/cart-item-list.component.ts:L395-L398, feature-libs/cart/base/components/add-to-cart/add-to-cart.component.ts:L158-L160, feature-libs/order/components/order-details/order-detail-reorder/order-detail-reorder.component.ts:L53-L53). Poiché il binding è nel root module eager, vale per tutto l'albero.

Schedule lines. `OrderEntry` è aumentato con `scheduleLines?: ScheduleLine[]`, dove `ScheduleLine = { confirmedAt?: Date; confirmedQuantity?: number }` (integration-libs/s4om/root/model/augmented-core.model.ts:L10-L14, integration-libs/s4om/root/model/schedule-line.model.ts:L7-L10); l'augmentation è importata per side effect dall'index del model (integration-libs/s4om/root/model/index.ts:L7-L9). `ScheduleLinesComponent` legge l'entry da `CartItemContext` (opzionale, fallback `EMPTY`) e fornisce localmente `CxDatePipe` (integration-libs/s4om/root/components/schedule-lines/schedule-lines.component.ts:L13-L27). Il template mostra le righe solo se `hasScheduleLines`, con il testo visivo `aria-hidden` e un testo `cx-visually-hidden` collegato da `aria-describedby` (integration-libs/s4om/root/components/schedule-lines/schedule-lines.component.html:L1-L20).

3.4 CPQ quote: sconti nella tabella delle righe

`CpqQuoteRootModule` è vuoto; tutta la logica è in `CpqDiscountModule`, importato da `CpqQuoteModule` (integration-libs/cpq-quote/root/cpq-quote-root.module.ts:L9-L10, integration-libs/cpq-quote/cpq-

quote.module.ts:L10-L13). CpqDiscountModule (integration-libs/cpq-quote/cpq-quote-discount/cpq-discount.module.ts:L39-L57):

- sostituisce CartItemListComponentService con useClass: CpqQuoteSharedService;
- registra tre componenti negli outlet CPQ_QUOTE_MODULE, CPQ_QUOTE_HEADING, CPQ_QUOTE (tutti AFTER).

Gli id degli outlet sono definiti nel **core cart** (cx-cpq-quote, cx-cpq-quote-heading, cx-cpq-quote-offer) (feature-libs/cart/base/root/models/cart-outlets.model.ts:L25-L27) e piazzati nei template core: CPQ_QUOTE_HEADING nell'intestazione della tabella con context items, CPQ_QUOTE e CPQ_QUOTE_MODULE nella riga con context { items: item } (feature-libs/cart/base/components/cart-shared/cart-item-list/cart-item-list.component.html:L21-L24, feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.html:L44-L49, feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.html:L106-L112). È un caso esemplare di "hook predisposto nel core per un'integrazione".

Il meccanismo del flag:

1. Il CartItemListComponentService core è providedIn: 'root' e ha un solo metodo showBasePriceWithDiscount() che ritorna true (feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.service.ts:L9-L16).
2. CartItemListRowComponent lo legge **una volta**, inizializzando il campo isFlagQuote, e lo usa in *ngIf per il prezzo base standard (feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.ts:L48-L49, feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.html:L37-L37).
3. CpqQuoteSharedService estende il servizio core e delega a CpqQuoteService.getFlag$(), che nonostante il $ ritorna un boolean sincrono dal BehaviorSubject (default true) (integration-libs/cpq-quote/cpq-quote-discount/cpq-qute-shared.service.ts:L16-L23, integration-libs/cpq-quote/cpq-quote-discount/cpq-qute.service.ts:L13-L22).
4. CpqQuoteHeadingComponent riceve dal context outlet l'array di entry e imposta il flag a !hasDiscounts: se almeno un item ha cpqDiscounts, il prezzo base standard va nascosto e compare la colonna sconto (integration-libs/cpq-quote/cpq-quote-discount/components/cpq-quote-heading/cpq-quote-heading.component.ts:L55-L72).
5. CpqQuoteDiscountComponent.getDiscountedPrice calcola il prezzo unitario scontato come (basePrice*quantity - appliedDiscount)/quantity (integration-libs/cpq-quote/cpq-quote-discount/components/cpq-quote-discount-tbody/cpq-quote.component.ts:L55-L71), formattato con number: '1.2-2' : 'en-US' e con il prezzo base barrato se ci sono sconti (integration-libs/cpq-quote/cpq-quote-discount/components/cpq-quote-discount-tbody/cpq-quote.component.html:L12-L31).
6. CpqQuoteOfferComponent mostra la percentuale appliedDiscount/(basePrice*quantity)*100, senza decimali se intera, altrimenti con 2 (integration-libs/cpq-quote/cpq-quote-discount/components/cpq-quote/cpq-quote-offer.component.ts:L52-L74).

Il dato arriva dal backend: OrderEntry è aumentato con cpqDiscounts?: CpqDiscounts[] (campi appliedValue, isoCode, value tipati any) (integration-libs/cpq-quote/root/model/augmented-core.model.ts:L10-L14, integration-libs/cpq-quote/root/model/cpqDiscounts.model.ts:L7-L11).

3.5 S/4HANA Service — parte root (eager)

S4ServiceRootModule (integration-libs/s4-service/root/s4-service-root.module.ts:L56-L83):

- importa CheckoutServiceDetailsEventModule;

- registra due route figlie `path: ''` identificate da `data.cxRoute` (`cancelServiceDetails`, `rescheduleServiceDetails`) con `CmsPageGuard` + `PageLayoutComponent` (integration-libs/s4-service/root/s4-service-root.module.ts:L59-L72). I path reali arrivano dalla routing config: `my-account/order/cancelservice/:orderCode` e `my-account/order/rescheduleservice/:orderCode` (con `paramsMapping orderCode → code`), più `checkout/service-details` (integration-libs/s4-service/root/config/default-service-orders-routing-config.ts:L9-L23). È il meccanismo generale per cui Spartacus identifica il nome di una route da `data.cxRoute` (core-libs/core/src/routing/configurable-routes/configurable-routes.service.ts:L146-L150; vedi 14 — Routing);
- **sostituisce il token** `CheckoutConfig` con `useValue: defaultServiceDetailsCheckoutConfig` (integration-libs/s4-service/root/s4-service-root.module.ts:L75-L75). Normalmente `CheckoutConfig` è un token astratto `useExisting: Config` che espone la configurazione globale fusa (feature-libs/checkout/base/root/config/checkout-config.ts:L18-L22): qui invece chi inietta `CheckoutConfig` riceve un oggetto fisso;
- fornisce default config per routing, delivery mode di servizio e `cmsComponents`, più `CxDatePipe` e `CheckoutServiceSchedulePickerService` (integration-libs/s4-service/root/s4-service-root.module.ts:L76-L80).

`defaultServiceDetailsCheckoutConfig` definisce 6 step (paymentType, deliveryAddress, deliveryMode, paymentDetails, **serviceDetails**, reviewOrder), `express: false`, `guest: false`, `defaultDeliveryMode: [FREE]` (integration-libs/s4-service/root/config/default-service-details-checkout-config.ts:L13-L57).

Estendere un enum del core. `CheckoutStepType.SERVICE_DETAILS` viene aggiunto sia per il type checker (augmentation di `enum`) sia a runtime con un'assegnazione diretta all'oggetto enum (integration-libs/s4-service/root/model/augmented-types.model.ts:L38-L47). Altre augmentation: `Order` riceve `servicedAt`, `serviceCancellable`, `serviceReschedulable`; `CheckoutState` riceve `servicedAt`; `BaseStore` riceve `serviceOrderConfiguration { leadDays, serviceScheduleTimes }`; `OccEndpoints` riceve `setServiceScheduleSlot` (integration-libs/s4-service/root/model/augmented-types.model.ts:L16-L52). `S4ServiceDeliveryModeConfig` è un config token con `s4ServiceDeliveryMode?: DeliveryMode` (integration-libs/s4-service/root/model/augmented-types.model.ts:L54-L64), di default `code: 'service-delivery'`, costo `USD0.00` (integration-libs/s4-service/root/config/default-service-delivery-mode-config.ts:L10-L22).

Nessuna feature lazy propria (di fatto). s4-service non mappa i suoi componenti CMS su una feature sua: estende `featureModules[CHECKOUT_FEATURE].cmsComponents` (B2B + `CheckoutServiceDetails`) e `featureModules[ORDER_FEATURE].cmsComponents` (order + 3 componenti service) (integration-libs/s4-service/root/s4-service-root.module.ts:L31-L55). Siccome `deepMerge` **sostituisce** gli array invece di concatenarli (`isObject` esclude gli array, quindi l'ultimo valore vince) (core-libs/core/src/config/utils/deep-merge.ts:L7-L9, core-libs/core/src/config/utils/deep-merge.ts:L36-L45), la libreria deve ripetere gli elenchi B2B/order completi. L'app demo registra comunque una feature `S4_SERVICE_FEATURE` (`'s4-service'`) che carica `S4ServiceModule`, il quale però è vuoto (projects/storefrontapp/src/app/spartacus/features/s4-service/s4-service-feature.module.ts:L26-L29, integration-libs/s4-service/s4-service.module.ts:L9-L12).

Facade. `CheckoutServiceDetailsFacade` è una facade lazy (`facadeFactory`) legata a `CHECKOUT_CORE_FEATURE` con 5 metodi (integration-libs/s4-service/root/facade/checkout-service-details.facade.ts:L13-L27); `CHECKOUT_CORE_FEATURE` è alias di `CHECKOUT_FEATURE` (feature-libs/checkout/base/root/checkout-root.module.ts:L44-L45), quindi il proxy carica il chunk checkout. Al contrario `CancelServiceOrderFacade` e `RescheduleServiceOrderFacade` sono classi astratte `providedIn: 'root'` **senza** factory: risolvibili solo dove `S4ServiceOrderCoreModule` le ha fornite (integration-libs/s4-service/root/facade/cancel-service-order.facade.ts:L12-L30, integration-libs/s4-service/root/facade/reschedule-service-order.facade.ts:L11-L24).

Utility date. `CheckoutServiceSchedulePickerService` legge `leadDays` e `serviceScheduleTimes` dal `baseSite.baseStore.serviceOrderConfiguration` (default 0 / `[]`) (integration-libs/s4-service/root/facade/checkout-

service-schedule-picker.service.ts:L48-L61); la data minima è oggi + `leadDays` + 1, formattata `yyyy-MM-dd` (integration-libs/s4-service/root/facade/checkout-service-schedule-picker.service.ts:L24-L32); `convertToDateTime` produce `YYYY-MM-DDTHH:MM:00` + offset del fuso locale (integration-libs/s4-service/root/facade/checkout-service-schedule-picker.service.ts:L70-L74); `convertDateTimeToReadableString` usa `Date.toLocaleString()` (integration-libs/s4-service/root/facade/checkout-service-schedule-picker.service.ts:L82-L85).

Evento. `CheckoutServiceDetailsEventListener` traduce ogni `CheckoutServiceDetailsSetEvent` in un `CheckoutQueryResetEvent` (integration-libs/s4-service/root/events/checkout-service-details-event.listener.ts:L23-L29), che è tra i notifier di reset della query dei dettagli checkout (feature-libs/checkout/base/core/facade/checkout-query.service.ts:L38-L39). Il listener è istanziato eagerly iniettandolo nel costruttore di `CheckoutServiceDetailsEventModule` (integration-libs/s4-service/root/events/checkout-service-details-event.module.ts:L10-L17). Per il pattern vedi 20 — Facade, command & query, eventi.

3.6 S/4HANA Service — checkout

`S4ServiceCheckoutModule` = components + core + occ (integration-libs/s4-service/checkout/s4-service-checkout.module.ts:L12-L19).

- **Core**: `CheckoutServiceDetailsFacade → useExisting CheckoutServiceDetailsService`, più il connector (integration-libs/s4-service/checkout/core/s4-service-checkout-core.module.ts:L13-L24). Il Command `setServiceScheduleSlotCommand` (strategia `CancelPrevious`) verifica le precondizioni, chiama il connector con `{ scheduledAt }` e a successo emette `CheckoutServiceDetailsSetEvent` (integration-libs/s4-service/checkout/core/facade/checkout-service-details.service.ts:L39-L65). Precondizioni: `userId` e `cartId` presenti, utente anonimo ammesso solo con guest cart, altrimenti `Error('Checkout conditions not met')` (integration-libs/s4-service/checkout/core/facade/checkout-service-details.service.ts:L67-L85). Lo stato della data servizio è derivato dalla query dei dettagli checkout (`state.data?.servicedAt`), senza store dedicato (integration-libs/s4-service/checkout/core/facade/checkout-service-details.service.ts:L91-L97). `getServiceProducts` filtra le entry con `productTypes === ProductTypes.SERVICE`; `hasNonServiceItems` confronta il numero di entry in consegna (`getDeliveryEntries()`, il pickup non si applica ai servizi) con quello dei servizi (integration-libs/s4-service/checkout/core/facade/checkout-service-details.service.ts:L99-L131).
- **OCC**: `CheckoutServiceDetailsAdapter → OccCheckoutServiceDetailsAdapter` e default config degli endpoint (integration-libs/s4-service/checkout/occ/s4-service-checkout-occ.module.ts:L13-L22). La config ridefinisce `getCheckoutDetails` aggiungendo `servicedAt` ai fields e introduce `setServiceScheduleSlot` (integration-libs/s4-service/checkout/occ/config/default-occ-checkout-s4-service-config.ts:L10-L25). L'adapter fa una `PATCH` del body e normalizza gli errori con `tryNormalizeHttpError` (integration-libs/s4-service/checkout/occ/adapter/occ-checkout-service-details.adapter.ts:L27-L44).
- **Components**:
  - `CheckoutStepsSetGuard` è sostituito con `useExisting: CheckoutServiceOrderStepsSetGuard` (integration-libs/s4-service/checkout/components/s4-service-checkout-component.module.ts:L14-L27). È il guard dichiarato dai componenti CMS di checkout progress (feature-libs/checkout/base/components/checkout-progress/checkout-progress.module.ts:L37-L37); anche il checkout B2B sostituisce lo stesso token (feature-libs/checkout/b2b/components/checkout-b2b-components.module.ts:L33-L36), quindi conta l'ordine di import nel wrapper (§3.1).
  - `CheckoutServiceOrderStepsSetGuard` estende `CheckoutB2BStepsSetGuard`; in `canActivate` disabilita SERVICE_DETAILS se il carrello non ha servizi e DELIVERY_MODE se ha solo servizi, poi delega a `super.canActivate` (integration-libs/s4-service/checkout/components/guards/checkout-service-order-steps-set.guard.ts:L21-L43). Sovrascrive `isB2BStepSet` aggiungendo il caso `SERVICE_DETAILS → isServiceDetailsSet` (integration-libs/s4-service/checkout/components/guards/checkout-service-

order-steps-set.guard.ts:L78-L99). isServiceDetailsSet prima chiama setServiceDeliveryMode() — che, se il carrello ha SOLO servizi, imposta il delivery mode s4ServiceDeliveryMode.code — poi ritorna true o l'URL dello step (integration-libs/s4-service/checkout/components/guards/checkout-service-order-steps-set.guard.ts:L45-L76).

- Override CMS CheckoutDeliveryMode → ServiceCheckoutDeliveryModeComponent (estende CheckoutDeliveryModeComponent) (integration-libs/s4-service/checkout/components/checkout-delivery-mode/service-checkout-delivery-mode.module.ts:L34-L42, integration-libs/s4-service/checkout/components/checkout-delivery-mode/service-checkout-delivery-mode.component.ts:L40-L47); il template mostra prima, se ci sono servizi, l'opzione "service delivery" presa dalla config (integration-libs/s4-service/checkout/components/checkout-delivery-mode/service-checkout-delivery-mode.component.html:L1-L5, integration-libs/s4-service/checkout/components/checkout-delivery-mode/service-checkout-delivery-mode.component.html:L133-L149).
- Override CMS CheckoutReviewOrder → ServiceCheckoutReviewSubmitComponent (estende B2BCheckoutReviewSubmitComponent) con guard CheckoutAuthGuard, CartNotEmptyGuard (integration-libs/s4-service/checkout/components/checkout-review-submit/service-checkout-review-submit.module.ts:L40-L49); aggiunge SERVICE_DETAILS ai "delivery steps" e nasconde la card delivery mode quando il mode è quello di servizio (integration-libs/s4-service/checkout/components/checkout-review-submit/service-checkout-review-submit.component.ts:L116-L126).
- Nuovo componente CMS CheckoutServiceDetails (cx-service-details) (integration-libs/s4-service/checkout/components/checkout-service-details/checkout-service-details.module.ts:L32-L41). Il form è precompilato con la data salvata o con data minima e primo orario disponibile (integration-libs/s4-service/checkout/components/checkout-service-details/checkout-service-details.component.ts:L85-L109); next() converte data+ora, chiama setServiceScheduleSlot e a successo checkoutStepService.next, a errore mostra serviceOrderCheckout.unknownError (integration-libs/s4-service/checkout/components/checkout-service-details/checkout-service-details.component.ts:L129-L164).

3.7 S/4HANA Service — order

- **Core**: CancelServiceOrderFacade → CancelServiceOrderService e RescheduleServiceOrderFacade → RescheduleServiceOrderService (useExisting), più i due connector (integration-libs/s4-service/order/core/s4-service-order-core.module.ts:L22-L39). cancelService prende lo userId e chiama il connector; loadOrderDetails delega a OrderHistoryFacade.getOrderDetails() (integration-libs/s4-service/order/core/facade/cancel-service-order.service.ts:L20-L38).
- **OCC**: cancelServiceOrder → users/${userId}/orders/${code}/serviceOrder/cancellation, rescheduleService → .../serviceOrder/serviceScheduleSlot (integration-libs/s4-service/order/occ/config/default-occ-s4-service-config.ts:L10-L15). Cancel è una POST senza normalizzazione errori; reschedule è una PATCH con tryNormalizeHttpError (integration-libs/s4-service/order/occ/adapters/occ-cancel-service-order.adapter.ts:L20-L32, integration-libs/s4-service/order/occ/adapters/occ-reschedule-service-order.adapter.ts:L26-L42).
- **Components**:
  - ServiceDetailsCardModule sostituisce OrderOverviewComponentService con ServiceOrderOverviewComponentService e mette ServiceDetailsCardComponent nell'outlet OrderOutlets.SERVICE_DETAILS (integration-libs/s4-service/order/components/order-summary/service-details-card.module.ts:L16-L31). Il servizio nasconde il delivery mode di servizio, altrimenti delega a super (integration-libs/s4-service/order/components/order-summary/service-order-overview-component.service.ts:L12-L20, feature-libs/order/components/order-details/order-overview/order-overview-component.service.ts:L12-L14). L'outlet cx-service-details-card è già nel template core dell'order overview con context { item: order, readonly: true } (feature-libs/

order/root/model/order-outlets.model.ts:L13-L13, feature-libs/order/components/order-details/order-overview/order-overview.component.html:L112-L115).

- Override CMS `AccountOrderDetailsActionsComponent → S4ServiceOrderDetailActionsComponent` (integration-libs/s4-service/order/components/s4-service-order-detail-actions/s4-service-order-detail-actions.module.ts:L28-L37); il template mostra i bottoni cancel/reschedule in base ai flag API `order.serviceCancellable/serviceReschedulable` e linka le cxRoute `cancelServiceDetails/rescheduleServiceDetails` (integration-libs/s4-service/order/components/s4-service-order-detail-actions/s4-service-order-detail-actions.component.html:L42-L57).
- Nuovi componenti CMS `CancelServiceOrder` (guard `AuthGuard, CancelServiceOrderGuard`), `CancelServiceOrderHeadline` (`AuthGuard`), `RescheduleServiceOrder` (`AuthGuard, ServiceOrderGuard`) (integration-libs/s4-service/order/components/cancel-service-order/cancel-service-order.module.ts:L34-L41, integration-libs/s4-service/order/components/cancel-service-order-headline/cancel-service-order-headline.module.ts:L38-L45, integration-libs/s4-service/order/components/reschedule-service-order/reschedule-service-order.module.ts:L45-L52).
- `CancelServiceOrderGuard` passa solo se l'ordine ha `serviceCancellable`, altrimenti `UrlTree` verso la route `orders` (integration-libs/s4-service/order/components/guards/cancel-service-order.guard.ts:L21-L37); `ServiceOrderGuard` passa solo se `serviceReschedulable`, altrimenti messaggio `rescheduleService.serviceNotReschedulable` e `false` (integration-libs/s4-service/order/components/guards/service-order.guard.ts:L20-L34).
- `CancelServiceOrderComponent` invia **tutte** le entry dell'ordine (`orderEntryNumber`, `quantity`) più il motivo, poi rinaviga ai dettagli con un messaggio (integration-libs/s4-service/order/components/cancel-service-order/cancel-service-order.component.ts:L59-L102); `RescheduleServiceOrderComponent` filtra le entry ai soli prodotti SERVICE e chiama `rescheduleService(orderCode, dateTime)` (integration-libs/s4-service/order/components/reschedule-service-order/reschedule-service-order.component.ts:L77-L85, integration-libs/s4-service/order/components/reschedule-service-order/reschedule-service-order.component.ts:L136-L163).

L'entry point `@spartacus/s4-service/order` esporta solo module e components (non core/occ), mentre `@spartacus/s4-service/checkout` esporta anche core e occ (integration-libs/s4-service/order/public_api.ts:L7-L8, integration-libs/s4-service/checkout/public_api.ts:L7-L10).

3.8 Punchout — parte root (eager)

Punchout è l'unica libreria del gruppo con una feature lazy "vera" (`punchout`) e con una parte eager corposa. `PunchoutRootModule` (integration-libs/punchout/root/punchout.root.module.ts:L36-L84):

1. importa `PunchoutNavigationModule`, che contribuisce `PunchoutNavigationGuard` al multi-token `BEFORE_CMS_PAGE_GUARD` (integration-libs/punchout/root/guards/punchout-navigation.module.ts:L12-L21);
2. fornisce tre default config (componenti CMS, routing, guard) e un `provideAppInitializer` che chiama `PunchoutStatePersistenceService.initSync()` (integration-libs/punchout/root/punchout.root.module.ts:L39-L47);
3. registra `PunchoutCartInterceptor` con `useExisting` nel multi-token `HTTP_INTERCEPTORS` (integration-libs/punchout/root/interceptors/index.ts:L11-L17);
4. sostituisce `AuthHttpHeaderService` con una **factory** dipendente dal feature toggle (§3.10) (integration-libs/punchout/root/punchout.root.module.ts:L49-L66);
5. contribuisce `PunchoutExpiredRefreshTokenHandler` a `EXPIRED_REFRESH_TOKEN_HANDLERS` (integration-libs/punchout/root/punchout.root.module.ts:L67-L71);

6. fornisce `PunchoutUiRestrictionService` e lo aggancia al componente root via `APP_BOOTSTRAP_LISTENER` (integration-libs/punchout/root/punchout.root.module.ts:L72-L81).

Stato. `PunchoutStoreService` è uno store minimale su `BehaviorSubject<PunchoutState>`: `setPunchoutState` sostituisce, `updatePunchoutState` fonde, `clearPunchoutState` ripristina lo stato iniziale (integration-libs/punchout/root/services/punchout-store.service.ts:L11-L49). Niente NgRx.

Persistenza. `initSync` sincronizza con `localStorage` (default di `syncWithStorage`), sotto la chiave `spartacus⚿⚿punchout` (key `punchout`, contesto vuoto), **solo** il `punchoutSessionId` (integration-libs/punchout/root/services/punchout-state-persistence.service.ts:L23-L36, core-libs/core/src/state/services/state-persistence.service.ts:L44-L48, core-libs/core/src/state/services/state-persistence.service.ts:L124-L130). Dopo l'avvio, un id assente è scritto come `''` e non `undefined`, perché `StatePersistenceService` non permette di cancellare una chiave già creata (integration-libs/punchout/root/services/punchout-state-persistence.service.ts:L42-L53). Al refresh, `onRead` ripristina l'id e richiama `initPunchoutSession({ isPageRefresh: true })`, salvo che si sia già sulla pagina di sessione (integration-libs/punchout/root/services/punchout-state-persistence.service.ts:L62-L76).

Rilevamento. `isPunchoutSessionPage` è vero se il path corrente (prima di `?`) contiene il path semantico `punchoutSession` **e** c'è una query string (integration-libs/punchout/root/services/punchout-detection.service.ts:L23-L34). Le route `punchout/cxml/session` e `punchout/cxml/error` sono `protected: false` e `authFlow: true` (integration-libs/punchout/root/config/default-punchout-routing-config.ts:L9-L30).

Interceptor. `PunchoutCartInterceptor` aggiunge l'header `punchoutsid` a ogni richiesta il cui URL contiene `/carts/{punchoutCartId}` (integration-libs/punchout/root/interceptors/punchout-cart.interceptor.ts:L17-L49).

Guard di navigazione. `PunchoutNavigationGuard.canActivate` calcola `cxRoute` (da `route.data.cxRoute` o dal path con `RoutingConfigService.getRouteName`), ricava l'operazione punchout e, se la route non è ammessa né per cxRoute né per URL, mostra un warning e naviga a `redirectPage` (integration-libs/punchout/root/guards/punchout-navigation.guard.ts:L36-L61). L'operazione è determinata solo per utente loggato con `punchoutSessionId`; se la sessione non è in stato la richiede via facade; ogni errore → `undefined`, cioè nessuna restrizione (integration-libs/punchout/root/guards/punchout-navigation.guard.ts:L96-L131). In `isAllowedUrls`, `'/'` significa "solo home" (route con `url.length === 0`), gli altri URL sono confrontati con `includes` sul path relativo (integration-libs/punchout/root/guards/punchout-navigation.guard.ts:L63-L82). Default: INSPECT ammette solo session/requisition/inspect e rimanda a `punchoutInspect`; EDIT/CREATE ammettono home + category, brand, quickOrder, product, cart, search, punchoutError e rimandano a `home` (integration-libs/punchout/root/config/default-punchout-guard-config.ts:L10-L46).

UI restriction. `PunchoutUiRestrictionService.isPunchoutSessionActive` aggiunge/rimuove la classe CSS `cxPunchoutSessionActive` sull'elemento root (integration-libs/punchout/root/services/punchout-ui-restriction.service.ts:L24-L58); gli stili con quella classe nascondono il bottone secondario del dialog "added to cart" e il bottone recensioni (integration-libs/punchout/styles/_punchout-template.scss:L49-L59).

3.9 Punchout — sessione e requisition (lazy)

`PunchoutFacade` è una facade lazy (`facadeFactory`, feature `punchout`) con 7 metodi (integration-libs/punchout/root/facade/punchout.facade.ts:L17-L37); la feature è mappata ai 6 componenti CMS punchout (integration-libs/punchout/root/config/default-punchout-cms-component-config.ts:L10-L23) e l'app demo aggiunge il loader (projects/storefrontapp/src/app/spartacus/features/punchout/punchout-feature.module.ts:L33-L40). `PunchoutModule` = components + core + occ; core lega `PunchoutFacade → useExisting PunchoutService`; occ lega `PunchoutAdapter → OccPunchoutAdapter` (integration-libs/punchout/punchout.module.ts:L12-L15, integration-libs/punchout/core/facade/facade-providers.ts:L11-L17, integration-libs/punchout/occ/punchout-occ.module.ts:L15-L25). Endpoint: `punchout/sessions/${sessionId}` e `.../`

`requisition`, quest'ultimo con `discardCartEntries=true` se richiesto (`integration-libs/punchout/occ/config/default-occ-punchout-config.ts:L10-L13`, `integration-libs/punchout/occ/adapters/occ-punchout.adapter.ts:L49-L69`).

Avvio sessione:

1. `PunchoutSessionComponent` (template vuoto) legge il query param `sid` e chiama `initPunchoutSession` (`integration-libs/punchout/components/punchout-session/punchout-session.component.ts:L17-L51`).
2. `getPunchoutSessionCommand`: senza id termina la sessione; altrimenti logout silenzioso → richiesta sessione OCC → login con il token ricevuto → load del carrello → stato → (solo EDIT, non refresh) snapshot della requisition iniziale → (non refresh) routing alla pagina target (`integration-libs/punchout/core/facade/punchout.service.ts:L69-L109`).
3. `requestPunchoutSessionCommand` mette in cache in memoria la prima risposta valida e la riusa; senza `accessToken`, `customerId` o `cartId` lancia `Error('Punchout login info missing')` (`integration-libs/punchout/core/facade/punchout.service.ts:L241-L261`).
4. `PunchoutAuthService.loginWithToken` scrive direttamente `access_token`, `access_token_stored_at`, `token_type` in `AuthStorageService`, imposta `OCC_USER_ID_CURRENT` e dispatcha `AuthActions.Login` (`integration-libs/punchout/core/services/punchout-auth.service.ts:L64-L75`). Non passa quindi per il flusso OAuth descritto in 22 — Autenticazione.
5. `routeToTargetPage`: CREATE/EDIT a livello PRODUCT con `selectedItem` → PDP; EDIT → cart; INSPECT → `punchoutInspect`; altrimenti `/` (`integration-libs/punchout/core/facade/punchout.service.ts:L298-L320`).

Ritorno al procurement:

1. I bottoni chiamano `submitRequisition(cancel)` o `closePunchoutSession()` (`integration-libs/punchout/components/punchout-buttons/punchout-buttons.component.ts:L36-L38`, `integration-libs/punchout/components/punchout-close-session/punchout-close-session.component.ts:L29-L31`).
2. `closePunchoutSessionCommand`: CREATE → `cancelRequisition: true` (si invia un carrello vuoto); EDIT → `closePunchoutSession: true` (si invia lo snapshot iniziale); poi apre la pagina requisition (`integration-libs/punchout/core/facade/punchout.service.ts:L194-L232`).
3. `getPunchoutRequisitionCommand` blocca la navigazione manuale alla pagina requisition (nessun flag in stato → warning + home), restituisce lo snapshot iniziale se si chiude una sessione EDIT, altrimenti chiama OCC (`integration-libs/punchout/core/facade/punchout.service.ts:L120-L171`).
4. `PunchoutRequisitionComponent` riempie un form nascosto `cxml-base64` con `orderAsCXML`, attende un tick (`timer(0)`), fa logout del punchout user e invia il form in POST a `browseFormPostUrl`, cioè al sistema di procurement (`integration-libs/punchout/components/punchout-requisition/punchout-requisition.component.ts:L42-L95`, `integration-libs/punchout/components/punchout-requisition/punchout-requisition.component.html:L1-L14`).

`endPunchoutSession` (auth service) pulisce lo stato, mostra `httpHandlers.unauthorized.common`, fa `coreLogout` e naviga a `punchoutError` (`integration-libs/punchout/core/services/punchout-auth.service.ts:L81-L97`).

3.10 Punchout e il refresh token scaduto: da override a handler

Questo è l'esempio più istruttivo del capitolo su come il core sia evoluto per **ridurre** gli override DI concorrenti.

- **Percorso legacy (toggle spento).** `PunchoutAuthHttpHeaderService` estende `AuthHttpHeaderService` e sovrascrive `handleExpiredRefreshToken`: sulla pagina di sessione fa logout silenzioso, con sessione attiva la termina, altrimenti `super` (`integration-libs/punchout/root/services/punchout-auth-http-header.`

service.ts:L24-L66). Il problema: anche ASM sostituisce `AuthHttpHeaderService` (feature-libs/asm/root/asm-root.module.ts:L73-L83), e un token può avere un solo vincitore.

- **Percorso nuovo (toggle acceso).** `AuthHttpHeaderService.handleExpiredRefreshToken` interroga in sequenza gli handler del multi-token `EXPIRED_REFRESH_TOKEN_HANDLERS` e usa il fallback (logout + login + messaggio) solo se nessuno ha gestito il caso (core-libs/core/src/auth/user-auth/services/auth-http-header.service.ts:L265-L285). Il commento core lo motiva esplicitamente: evitare di sovrascrivere l'intero servizio, "which would create a conflict with other service overrides (e.g., ASM)" (core-libs/core/src/auth/user-auth/services/auth-http-header.service.ts:L311-L316). `PunchoutExpiredRefreshTokenHandler` riproduce la logica punchout e ritorna `of(false)` se non applicabile (integration-libs/punchout/root/services/punchout-expired-refresh-token-handler.service.ts:L31-L45).
- **Ponte di compatibilità.** Il provider factory di Punchout per `AuthHttpHeaderService` sceglie: con toggle attivo `DELEGATED_AUTH_HTTP_HEADER_SERVICE` (fornito da ASM) o, in sua assenza, `DEFAULT_AUTH_HTTP_HEADER_SERVICE`; con toggle spento `PunchoutAuthHttpHeaderService` (integration-libs/punchout/root/punchout.root.module.ts:L49-L66). `DEFAULT_AUTH_HTTP_HEADER_SERVICE` crea un `AuthHttpHeaderService` "pulito" con `new`; entrambi i token sono dichiarati temporanei (fix CXPSA-12514) (core-libs/core/src/auth/user-auth/services/auth-http-header.service.ts:L50-L70); `DELEGATED_AUTH_HTTP_HEADER_SERVICE` è un hook senza factory perché Punchout possa delegare all'override ASM senza importarlo (core-libs/core/src/auth/user-auth/services/auth-http-header.service.ts:L72-L82). ASM fornisce entrambi i token (feature-libs/asm/root/asm-root.module.ts:L73-L83).
- Il toggle `enableExpiredRefreshTokenHandlers` vale `true` nei default ed è attivo anche nell'app demo (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1072-L1072, projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L360-L360). Vedi 42 — Feature toggle.

3.11 EPD Visualization (deprecata)

Tutta la libreria è `@deprecated since v221121.5.0` (integration-libs/epd-visualization/epd-visualization.module.ts:L12-L22). `EpdVisualizationRootModule` mappa la feature `epd-visualization` al componente CMS `VisualPickingTabComponent`, fornisce la default config e un config validator (integration-libs/epd-visualization/root/epd-visualization-root.module.ts:L17-L38).

Config. `EpdVisualizationConfig.epdVisualization` contiene `ui5.bootstrapUrl`, `apis.baseUrl`, `usageIds` (folder/product) e `visualPicking.productReferenceType` (integration-libs/epd-visualization/root/config/epd-visualization-config.ts:L19-L104). I default coprono solo usage id (`CommerceCloud-Folder`, `CommerceCloud-SparePart/ProductCode`) e `productReferenceType: 'SPAREPART'`, **non** `apis` né `ui5` (integration-libs/epd-visualization/root/config/epd-visualization-default-config.ts:L12-L35); l'app demo li fornisce (projects/storefrontapp/src/app/spartacus/features/epd-visualization/epd-visualization-feature.module.ts:L24-L31). Il validator controlla presenza e protocollo http/https delle URL, gli usage id e `productReferenceType` (integration-libs/epd-visualization/root/config/epd-visualization-config-validator.ts:L16-L39), ma i validator girano solo in dev mode e producono soltanto `logger.warn` (core-libs/core/src/config/config-validator/config-validator.module.ts:L28-L35, core-libs/core/src/config/config-validator/config-validator.ts:L42-L47).

API. `EpdVisualizationApiModule` lega gli adapter astratti core a implementazioni REST v1 (`SceneAdapter → StorageV1Adapter`, `VisualizationAdapter → VisualizationV1Adapter`), che non sono nella public API (integration-libs/epd-visualization/epd-visualization-api/epd-visualization-api.module.ts:L18-L24, integration-libs/epd-visualization/epd-visualization-api/public_api.ts:L7-L10). `StorageV1Adapter.getNodes` chiama `${baseUrl}/vis/public/storage/v1/scenes/{sceneId}/nodes` (integration-libs/epd-visualization/epd-visualization-api/adapters/storage-v1/storage-v1.adapter.ts:L49-L108); `VisualizationV1Adapter.lookupVisualization` chiama `.../visualization/v1/lookup/visualization?usage=…`

`&folderUsageId=…` con usage id serializzati in JSON e URI-encoded (integration-libs/epd-visualization/epd-visualization-api/adapters/visualization-v1/visualization-v1.adapter.ts:L50-L68).

Core. `VisualizationLookupService.findMatchingVisualizations` costruisce lo usage id del prodotto e tiene solo visualizzazioni `3DModel` o `2DDrawing` (integration-libs/epd-visualization/core/services/visualization-lookup/visualization-lookup.service.ts:L39-L69). `SceneNodeToProductLookupService.populateMapsForScene` scarica i nodi della scena e popola due mappe bidirezionali nodeId ↔ productCodes in `BehaviorSubject` (integration-libs/epd-visualization/core/services/scene-node-to-product-lookup/scene-node-to-product-lookup.service.ts:L52-L102), con varianti sincrone che ritornano `[]` finché le mappe non sono popolate (integration-libs/epd-visualization/core/services/scene-node-to-product-lookup/scene-node-to-product-lookup.service.ts:L184-L234).

Componenti e UI5.

1. `VisualPickingTabComponent` ottiene `VisualViewerService` e `VisualPickingProductListService` dai figli con `@ViewChild(..., { read: Service })` e li passa a `VisualPickingTabService.initialize` in `ngAfterViewInit` (integration-libs/epd-visualization/components/visual-picking/visual-picking-tab/visual-picking-tab.component.ts:L36-L59).
2. `initialize` (solo browser) collega la lista filtrata a `includedProductCodes` del viewer e, quando arrivano le product references, chiama `loadVisualization(currentProduct.code)` (integration-libs/epd-visualization/components/visual-picking/visual-picking-tab/visual-picking-tab.service.ts:L46-L89).
3. Le references sono caricate per il tipo `visualPicking.productReferenceType` via `ProductReferenceService` (integration-libs/epd-visualization/components/visual-picking/visual-picking-tab/product-list/visual-picking-product-list.service.ts:L109-L128).
4. `VisualViewerComponent` fornisce un'istanza propria di `VisualViewerService` e tutti i suoi `@Input/@Output` sono proxy verso il servizio (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.component.ts:L27-L50).
5. Il costruttore di `VisualViewerService` in SSR non fa nulla; in browser concatena bootstrap UI5 → init librerie → creazione viewport (`shareReplay`) (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L78-L99). `bootstrapUi5` inietta uno `<script>` in `<head>` con `src = ui5.bootstrapUrl` e callback globale `document.onUi5Bootstrapped`, saltando se UI5 è già presente (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1105-L1140); `initializeUi5` carica `sap.m`, `sap.ui.layout`, `sap.ui.vk`, `sap.ui.richtexteditor` (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1142-L1158); `addViewport` crea Viewport e collaboratori via `sap.ui.require` e lo piazza sull'elemento host (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1304-L1389).
6. `loadVisualization` risolve la visualizzazione (0 / 1 / >1 match → `NoMatchFound`, `UniqueMatchFound`, `MultipleMatchesFound`), popola le mappe nodi-prodotti e carica la scena; in SSR ritorna subito un `UnexpectedError` (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1032-L1092, integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1402-L1449). `loadScene` crea un `ContentResource` con `source: ${baseUrl}/vis/public/storage/v1` e `useSecureConnection: false` (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1549-L1565).

`CompactAddToCartComponent` estende `AddToCartComponent` del secondary entry `@spartacus/cart/base/components/add-to-cart` cambiando solo il template (integration-libs/epd-visualization/components/visual-picking/visual-picking-tab/product-list/compact-add-to-cart/compact-add-to-cart.component.ts:L10-L29).

3.12 Packaging: schematics, stili, test

Schematics `ng-add`**.** Le sei factory hanno lo stesso corpo: `validateSpartacusInstallation`, `analyzeCrossFeatureDependencies`, poi la catena `analyzeApplication` → `addFeatures` → `addPackageJsonDependenciesForLibrary(peerDependencies)` → `finalizeInstallation` (integration-libs/omf/schematics/add-omf/index.ts:L25-L43, integration-libs/s4om/schematics/add-s4om/index.ts:L25-L43, integration-libs/cpq-quote/schematics/add-cpq-quote/index.ts:L25-L43, integration-libs/punchout/schematics/add-punchout/index.ts:L25-L43, integration-libs/epd-visualization/schematics/add-epd-visualization/index.ts:L25-L48). La conoscenza specifica (dipendenze, root module, `importAfter`) sta in `core-libs/schematics`, ad es. `S4OM_SCHEMATICS_CONFIG` (core-libs/schematics/src/shared/lib-configs/integration-libs/s4om-schematics-config.ts:L28-L59); per questo `integration-libs/s4om/schematics/constants.ts` è un doppione inerte, con nomi che divergono (`S4OM_MODULE_NAME` vs `S4OM_FEATURE_MODULE_NAME`) (integration-libs/s4om/schematics/constants.ts:L9-L17, core-libs/schematics/src/shared/lib-configs/integration-libs/s4om-schematics-config.ts:L19-L26). Lo spec punchout copre solo il caso senza feature (integration-libs/punchout/schematics/add-punchout/index_spec.ts:L31-L45).

Stili. OMF e CPQ non hanno Sass. Punchout, s4-service ed EPD seguono lo schema placeholder + allowlist + `$skipComponentStyles`; punchout aggiunge un'allowlist di page template che estende `%PunchoutTemplate` su `cx-page-layout.PunchoutTemplate` (integration-libs/punchout/_index.scss:L7-L40, integration-libs/epd-visualization/_index.scss:L5-L29). In s4-service i partial di reschedule e detail actions definiscono classi globali anziché placeholder, quindi sono sempre applicati e non disattivabili via allowlist (integration-libs/s4-service/styles/components/_reschedule-service-order.scss:L1-L34, integration-libs/s4-service/styles/components/_s4-service-order-detail-actions.scss:L1-L7); lo stesso vale per integration-libs/s4om/styles/schedule-lines.scss:L1-L27.

Test. OMF, S4OM, CPQ e s4-service usano Vitest; punchout ed EPD restano su Karma (integration-libs/punchout/project.json:L20-L26) con un `test.ts` custom che aggiunge `provideZoneChangeDetection()` per evitare gli NG0100 introdotti da Angular 21 (integration-libs/punchout/test.ts:L14-L30, integration-libs/epd-visualization/test.ts:L16-L32). Le soglie di coverage differiscono: 90/90/75/90 per OMF e S4OM, 85/85/65/85 per CPQ e s4-service; in CPQ la coverage non ha `enabled: true` e la costante `root` è dichiarata ma non usata (integration-libs/omf/vitest.config.ts:L24-L46, integration-libs/s4om/vitest.config.ts:L42-L47, integration-libs/cpq-quote/vitest.config.ts:L11-L11, integration-libs/cpq-quote/vitest.config.ts:L26-L42, integration-libs/s4-service/vitest.config.ts:L43-L48).

---

4. Diagrammi

4.1 Dove vive ogni override (injector root vs chunk lazy)

■ **TAVOLA 36.1** diagramma a tutta pagina, in fondo al capitolo

Le frecce dentro i chunk rappresentano l'ordine di import nel wrapper (projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L14-L27, projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts:L16-L33, projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L14-L25): a parità di token vince il modulo più a destra/in basso.

4.2 OMF: dal link dello storico al dettaglio con header guid

■ TAVOLA 36.2 diagramma a tutta pagina, in fondo al capitolo

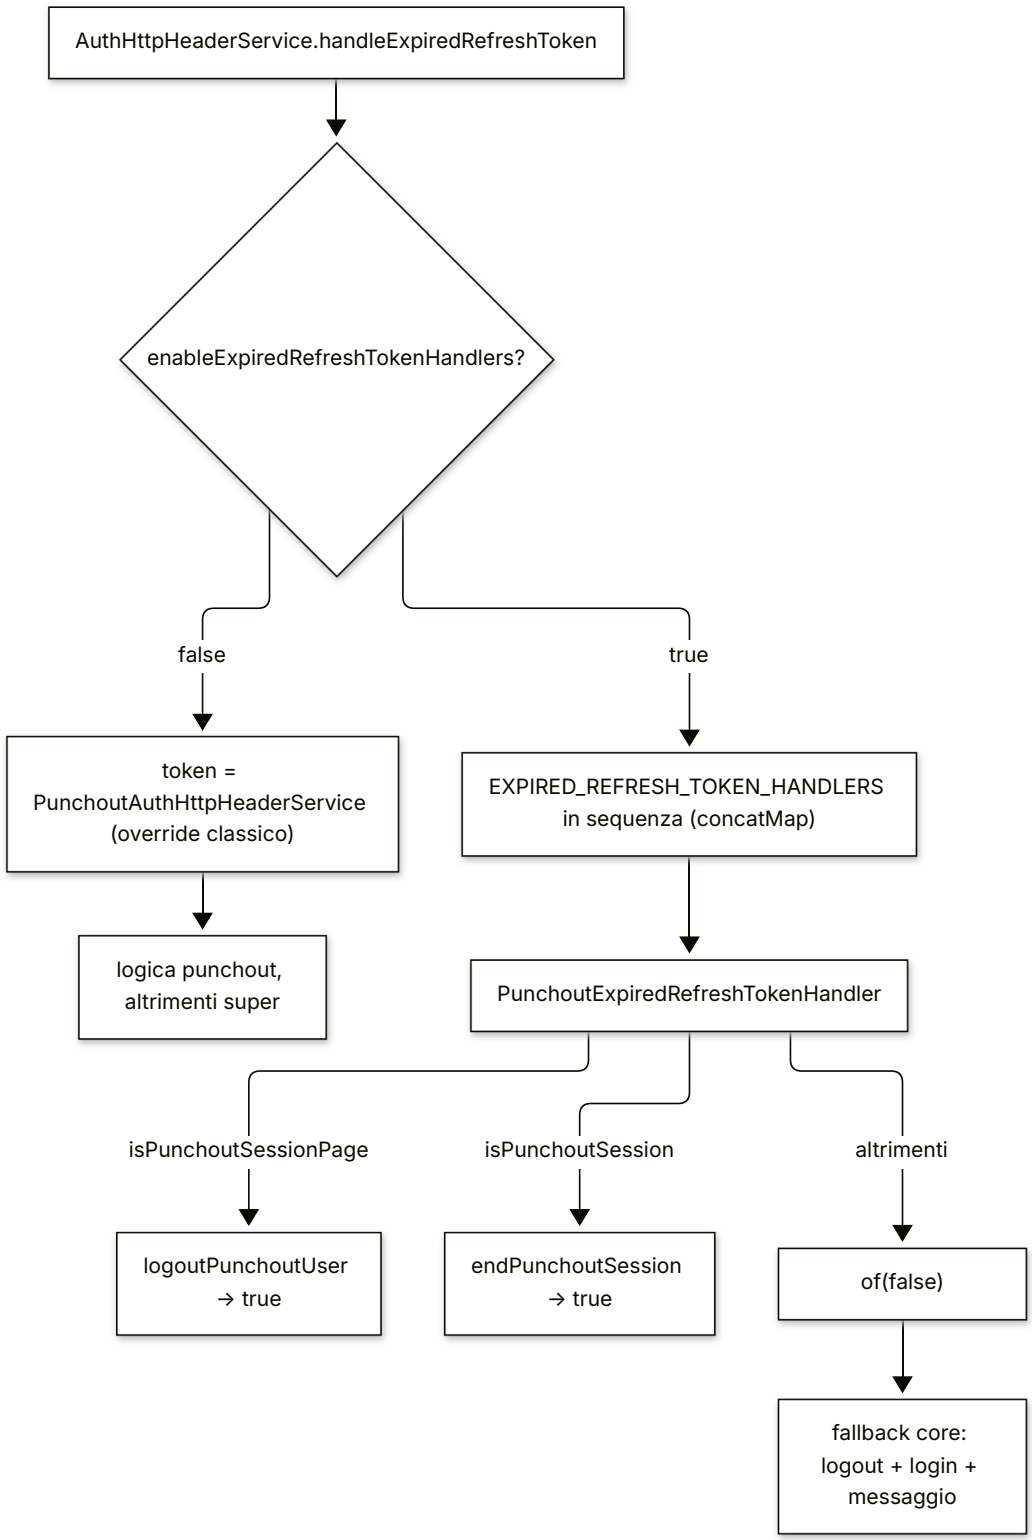
4.3 S/4 Service: step "service details" del checkout

■ TAVOLA 36.3 diagramma a tutta pagina, in fondo al capitolo

4.4 Punchout: ciclo di vita della sessione

■ TAVOLA 36.4 diagramma a tutta pagina, in fondo al capitolo

4.5 Refresh token scaduto: handler vs override



4.6 EPD: visual picking

■ **TAVOLA 36.5** diagramma a tutta pagina, in fondo al capitolo

5. Estratti di codice reale

5.1 Ordine degli import nel wrapper lazy order

projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L14-L27

```ts
const extensions: Type<any>[] = [];
if (environment.s4Service) {
  extensions.push(S4ServiceOrderModule);
}
if (environment.omf) {
  extensions.push(OmfOrderModule);
}
if (environment.opf) {
  extensions.push(OpfOrderModule);
}
@NgModule({
  imports: [OrderModule, ...extensions],
})
export class OrderWrapperModule {}
```

5.2 OMF: doppio override DI

integration-libs/omf/order/omf-order.module.ts:L15-L26

```ts
@NgModule({
  providers: [
    OmfOrderHistoryService,
    provideDefaultConfig(defaultOmfConfig),
    { provide: OrderHistoryAdapter, useClass: OccOmfOrderHistoryAdapter },
    {
      provide: OrderHistoryFacade,
      useClass: OmfOrderHistoryService,
    },
  ],
})
export class OmfOrderModule {}
```

5.3 OMF: guid da query param o dallo store, e header

integration-libs/omf/order/occ-omf-order-history.adapter.ts:L39-L67

```ts
  getOrderGuid(orderCode: string): Observable<string | undefined> {
    return this.route.queryParams.pipe(
      switchMap((queryParams) => {
        if (queryParams.guid) {
          // when navigating from Order History to Order Details page
```

```
          return of(queryParams.guid);
        } else {
          // when loading Order History page in case of My-Account-V2
          return this.getOrderDetailsValue(orderCode).pipe(
            map((order) => (order ? order.guid : undefined))
          );
        }
      })
    );
  }

  getRequestHeader(guid: string | undefined): HttpHeaders {
    let headers = new HttpHeaders();
    if (!this.config.omf?.guidHttpHeaderName && isDevMode()) {
      this.logger.warn(
        `There is no guidHttpHeaderName configured in OMF configuration`
      );
    }
    const guidHeader = this.config.omf?.guidHttpHeaderName?.toLowerCase?.();
    if (guid && guidHeader) {
      headers = headers.set(guidHeader, guid);
    }
    return headers;
  }
```

5.4 S4OM: outlet + override di servizio core

integration-libs/s4om/root/s4om-root.module.ts:L17-L35

TS

```
@NgModule({

7. Commenti e note notevoli dal sorgente

- *"below provider should be removed after enableExpiredRefreshTokenHandlers is fully rolled out"* — il provider factory di `AuthHttpHeaderService` di Punchout è dichiaratamente transitorio (integration-libs/punchout/root/punchout.root.module.ts:L49-L49).

- *"delegatedService is expected to be used by ASM to address breaking changes of CXSPA-12514"* (integration-libs/punchout/root/punchout.root.module.ts:L60-L60).
- *"This approach allows features like Punchout to handle expired tokens without needing to override the entire AuthHttpHeaderService via DI, which would create a conflict with other service overrides (e.g., ASM)."* — la motivazione degli handler nel core (core-libs/core/src/auth/user-auth/services/auth-http-header.service.ts:L311-L316).
- *"It is a workaround to address CXSPA-9608 - Public pages not displayed when token is invalid. To be removed once CXSPA-9608 is closed."* — sull'handler punchout (integration-libs/punchout/root/services/punchout-expired-refresh-token-handler.service.ts:L28-L29) e identico sul servizio legacy (integration-libs/punchout/root/services/punchout-auth-http-header.service.ts:L53-L54).
- *"Note that StatePersistenceService does not allow to delete key/value once it has been created."* (integration-libs/punchout/root/services/punchout-state-persistence.service.ts:L50-L50).
- *"handle race condition with logout guard, it needs to be assessed before punchout session is requested"* (integration-libs/punchout/root/guards/punchout-navigation.guard.ts:L110-L110).
- *"punchoutSession ajax request will always return same response during a punchout session."* — giustificazione della cache in memoria (integration-libs/punchout/core/facade/punchout.service.ts:L53-L57).
- *"timer(0) wait for next Javascript event loop, this way DOM native elements becomes accessible."* (integration-libs/punchout/components/punchout-requisition/punchout-requisition.component.ts:L85-L85).
- *"@deprecated since 221121.1 - Displaying the individual action buttons will depend on their boolean flags from API response."* — su `displayActions$` e `checkServiceStatus` (integration-libs/s4-service/order/components/s4-service-order-detail-actions/s4-service-order-detail-actions.component.ts:L49-L52, integration-libs/s4-service/order/components/s4-service-order-detail-actions/s4-service-order-detail-actions.component.ts:L60-L63).
- *"//check if we need to add serializer and normalizer."* — l'adapter checkout s4-service non converte il payload (integration-libs/s4-service/checkout/occ/adapter/occ-checkout-service-details.adapter.ts:L38-L38).
- *"//guards: inherited from standard config,"* — l'override CMS delle detail actions non ridichiara i guard (integration-libs/s4-service/order/components/s4-service-order-detail-actions/s4-service-order-detail-actions.module.ts:L33-L33).
- *"TODO:#9574 - we should be able to remove the spread of `CHECKOUT_BASE_CMS_COMPONENTS`."* — ereditato da `CHECKOUT_B2B_CMS_COMPONENTS`, usato da s4-service (feature-libs/checkout/b2b/root/checkout-b2b-root.module.ts:L24-L27).
- *"Adding dependency with Requested Delivery Date so that the library gets installed along with S4OM"* (integration-libs/s4om/root/s4om-root.module.ts:L20-L21).
- *"@deprecated: Method doesn't pass facade method's requirements (returns void or Observable)"* — su `getQueryParams`, proprio il metodo su cui si appoggia OMF (feature-libs/order/root/facade/order-history.facade.ts:L145-L148).
- *"@deprecated since v221121.5.0 - The epd-visualization integration library will be removed in the future."* (integration-libs/epd-visualization/root/epd-visualization-root.module.ts:L28-L30).
- *"Not in Spartacus public API since the /storage/v1 prefix will be deprecated and relocated"* (integration-libs/epd-visualization/epd-visualization-api/public_api.ts:L9-L10) e analogo nell'adapter (integration-libs/epd-visualization/epd-visualization-api/adapters/storage-v1/storage-v1.adapter.ts:L28-L31).
- *"Important: Please check the End of Cloud Provisioning column..."* su `ui5.bootstrapUrl`: la versione UI5 va scelta tra quelle ancora servite (integration-libs/epd-visualization/root/config/epd-visualization-config.ts:L52-L58).

- *"add $filter when usageId filtering available in backend"* (integration-libs/epd-visualization/core/services/scene-node-to-product-lookup/scene-node-to-product-lookup.service.ts:L80-L80).
- Commento di file errato *"Public API Surface of estimated-delivery-date"* nella public API di cpq-quote (integration-libs/cpq-quote/public_api.ts:L7-L9).

8. Extension point

EXTENSION POINT	COME SI USA	EXPORT	RICETTA
`OmfConfig` / `OmfConfiguration` (`guidHttpHeaderName`)	`provideConfig({ omf: { guidHttpHeaderName: '...' } })`	`OmfConfiguration` da `@spartacus/omf/root` (integration-libs/omf/root/public_api.ts:L7-L8); `OmfConfig` **non** è esportato da integration-libs/omf/order/public_api.ts:L7-L9	50 — Ricette config e DI
`OccOmfOrderHistoryAdapter`, `OmfOrderHistoryService`	sottoclasse + provider nel wrapper order, dopo `OmfOrderModule`	`@spartacus/omf/order` (integration-libs/omf/order/public_api.ts:L7-L9)	52 — Ricette OCC
`S4omProductCatalogService` (override di `ProductCatalogService`)	sottoclasse e `useExisting`	`@spartacus/s4om/root` (integration-libs/s4om/root/public_api.ts:L7-L12)	50 — Ricette config e DI
`ScheduleLinesComponent` / outlet `CartOutlets.ITEM_DETAILS`	`provideOutlet` con altro componente	`@spartacus/s4om/root`	51 — Ricette CMS, outlet, layout
`CpqQuoteService`, `CpqQuoteSharedService`, componenti CPQ; outlet `CPQ_QUOTE_MODULE/HEADING/CPQ_QUOTE`	override servizi, `provideOutlet`	`@spartacus/cpq-quote` (integration-libs/cpq-quote/cpq-quote-discount/public_api.ts:L7-L12); outlet in `@spartacus/cart/base/root` (feature-libs/cart/base/root/models/cart-outlets.model.ts:L25-L27)	51 — Ricette CMS, outlet, layout
`CheckoutServiceDetailsFacade` (lazy)	iniettare per leggere/scrivere lo slot	`@spartacus/s4-service/root` (integration-libs/s4-service/root/public_api.ts:L7-L12)	53 — Feature, cart/checkout
`CancelServiceOrderFacade`, `RescheduleServiceOrderFacade`	iniettabili solo nel chunk order	`@spartacus/s4-service/root`	50 — Ricette config e DI
`CheckoutServiceSchedulePickerService`	sottoclasse per formati data	`@spartacus/s4-service/root`	50 — Ricette config e DI
`S4ServiceDeliveryModeConfig`	`provideConfig({ s4ServiceDeliveryMode: {...} })`	`@spartacus/s4-service/root`	50 — Ricette config e DI
`CheckoutServiceDetailsSetEvent`	`EventService.get(...)`	`@spartacus/s4-service/root` (integration-libs/s4-service/root/events/checkout-service-details.events.ts:L18-L28)	50 — Ricette eventi

EXTENSION POINT	COME SI USA	EXPORT	RICETTA
`CheckoutServiceDetailsAdapter` / `OccCheckoutServiceDetailsAdapter`	adapter custom	`@spartacus/s4-service/checkout` (integration-libs/s4-service/checkout/public_api.ts:L7-L10)	52 — Ricette OCC
`CheckoutServiceOrderStepsSetGuard`	sottoclasse + `useExisting` su `CheckoutStepsSetGuard` nel wrapper checkout, dopo s4-service	`@spartacus/s4-service/checkout`	53 — Checkout step e guard
`Cancel/RescheduleServiceOrderAdapter`	**non esportati** (integration-libs/s4-service/order/public_api.ts:L7-L8)	—	54 — API pubblica vs interna
`ServiceOrderOverviewComponentService`, guard e componenti order	override servizio / mapping CMS	`@spartacus/s4-service/order`	51 — Ricette CMS, outlet, layout
`S4_SERVICE_CMS_COMPONENTS`, `S4_SERVICE_ORDER_CMS_COMPONENTS`	riuso quando si estendono di nuovo i `cmsComponents` di checkout/order	`@spartacus/s4-service/root`	53 — Feature lazy
`PunchoutNavigationGuardConfig`	`provideConfig({ punchoutNavigation: {...} })`	`@spartacus/punchout/root` (integration-libs/punchout/root/config/index.ts:L7-L10)	50 — Ricette config e DI
`PunchoutFacade`	facade lazy	`@spartacus/punchout/root`	50 — Ricette config e DI
Servizi punchout root (`PunchoutStoreService`, `PunchoutDetectionService`, `PunchoutUiRestrictionService`, `PunchoutStatePersistenceService`, `PunchoutExpiredRefreshTokenHandler`, `PunchoutAuthHttpHeaderService`)	sottoclasse + provider	`@spartacus/punchout/root` (integration-libs/punchout/root/public_api.ts:L7-L13)	50 — Ricette config e DI
`PunchoutNavigationGuard` (`BEFORE_CMS_PAGE_GUARD`)	multi provider aggiuntivo	`@spartacus/punchout/root`; `PunchoutCartInterceptor` **non** esportato	50 — Ricette interceptor
`PunchoutAdapter`, `PunchoutConnector`, `PUNCHOUT_SESSION_NORMALIZER`, `PUNCHOUT_REQUISITION_NORMALIZER`, `PunchoutService`, `PunchoutAuthService`	adapter/converter custom	`@spartacus/punchout/core`	52 — Ricette OCC
`EXPIRED_REFRESH_TOKEN_HANDLERS`	multi provider di un handler	`@spartacus/core` (core-libs/core/src/auth/user-auth/services/auth-http-header-handler.ts:L21-L23)	50 — Ricette config e DI
`EpdVisualizationConfig`	`provideConfig({ epdVisualization: {...} })`	`@spartacus/epd-visualization/root`	50 — Ricette config e DI
`SceneAdapter`, `VisualizationAdapter`, `NODES_RESPONSE_NORMALIZER`, `LOOKUP_VISUALIZATIONS_RESPONSE_NORMALIZER`	adapter/converter custom (libreria deprecata)	`@spartacus/epd-visualization/core`	52 — Ricette OCC

8.1 Esempio: cambiare il nome dell'header OMF

Solo config, nessun codice: `OmfConfig` legge da `Config` (integration-libs/omf/order/config/omf-config.ts:L11-L17), quindi basta un `provideConfig` in qualunque injector che contribuisca alla config globale (vedi 11 — Configurazione).

```ts
// esempio illustrativo (simboli: provideConfig da @spartacus/core)
provideConfig({
  omf: { guidHttpHeaderName: 'X-Order-Guid' },
});
```

L'adapter convertirà comunque il nome in minuscolo (integration-libs/omf/order/occ-omf-order-history.adapter.ts:L62-L62).

8.2 Esempio: aggiungere una route ammessa durante il punchout

`punchoutNavigation` è letto tramite `PunchoutNavigationGuardConfig`, `useExisting: Config` (integration-libs/punchout/root/config/punchout-guard-config.ts:L12-L34). Poiché `deepMerge` sostituisce gli array (core-libs/core/src/config/utils/deep-merge.ts:L36-L45), una `allowedCxRoutes` custom deve **ripetere** tutte le route di default, non solo aggiungere la nuova.

```ts
// esempio illustrativo: tutte le route di default di EDIT + 'myCustomRoute'
provideConfig({
  punchoutNavigation: {
    [PunchOutOperation.EDIT]: {
      allowedUrls: ['/'],
      allowedCxRoutes: [
        'punchoutSession', 'punchoutRequisition',
        'category', 'brand', 'quickOrder', 'product', 'cart', 'search', 'punchoutError',
        'myCustomRoute',
      ],
      redirectPage: { cxRoute: 'home' },
    },
  },
});
```

DA VERIFICARE: il tipo `PunchoutNavigationGuardConfig.punchoutNavigation` dichiara obbligatorie tutte e tre le chiavi di operazione (integration-libs/punchout/root/config/punchout-guard-config.ts:L17-L33); se `provideConfig` richieda un cast per una config parziale non è verificabile senza compilare (`node_modules` assente).

8.3 Esempio: personalizzare il guard degli step s4-service

Il guard va registrato **nello stesso injector** e **dopo** `S4ServiceCheckoutModule` (cioè in coda alle `extensions` di `CheckoutWrapperModule`), altrimenti verrà sovrascritto (projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts:L16-L33).

```ts
// esempio illustrativo
@Injectable({ providedIn: 'root' })
export class MyStepsSetGuard extends CheckoutServiceOrderStepsSetGuard {
  // override di canActivate / isB2BStepSet ...
}

@NgModule({
  providers: [{ provide: CheckoutStepsSetGuard, useExisting: MyStepsSetGuard }],
})
export class MyCheckoutExtensionModule {}
// CheckoutWrapperModule: imports: [CheckoutModule, ...extensions, MyCheckoutExtensionModule]
```

---

9. Trappole, casi limite, comportamenti controintuitivi

1. `CheckoutConfig` **sostituito, non fuso.** `{ provide: CheckoutConfig, useValue: defaultServiceDetailsCheckoutConfig }` nel root module eager: chi inietta `CheckoutConfig` ottiene SOLO quell'oggetto, quindi un `provideConfig({ checkout: ... })` dell'app non è visibile tramite quel token (lo è via `Config`) (integration-libs/s4-service/root/s4-service-root.module.ts:L75-L75 vs feature-libs/checkout/base/root/config/checkout-config.ts:L18-L22). Per personalizzare gli step con s4-service attivo bisogna ri-sostituire il token.
2. **Competizione su** `CheckoutStepsSetGuard`**.** B2B e s4-service lo sostituiscono nello stesso injector lazy: vince l'ultimo modulo importato. Se s4-service fosse importato prima di `CheckoutB2BModule`, il guard s4 verrebbe perso e lo step SERVICE_DETAILS non sarebbe mai verificato (feature-libs/checkout/b2b/components/checkout-b2b-components.module.ts:L33-L36, projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts:L16-L31).
3. **Gli array** `cmsComponents` **non si fondono.** Se un'altra libreria registra `featureModules[CHECKOUT_FEATURE].cmsComponents` dopo s4-service senza includere `CheckoutServiceDetails`, quel componente non viene più caricato lazy (core-libs/core/src/config/utils/deep-merge.ts:L36-L45).
4. **Override fuori dal wrapper.** `OmfOrderModule` (e gli override s4-service di token forniti dal chunk, come `OrderOverviewComponentService` e `CheckoutStepsSetGuard`) funzionano solo se importati nello stesso injector (wrapper lazy) e dopo il modulo feature; importarli nell'AppModule non sovrascriverebbe i provider del chunk lazy (projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L24-L26, feature-libs/order/components/order-details/order-details.module.ts:L127-L127). DA VERIFICARE a runtime (deduzione dalla gerarchia degli injector lazy). `CpqQuoteModule` non rientra in questa trappola: `CartItemListComponentService` ha solo `providedIn: 'root'` e il suo unico consumatore lo inietta con `inject(CartItemListComponentService)`, quindi non c'è un binding nel chunk da oscurare e un provider registrato nell'injector root avrebbe comunque la precedenza sul fallback `providedIn: 'root'` (feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.service.ts:L9-L16, feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.ts:L48-L48).
5. **Più istanze di facade order con OMF.** `OmfOrderModule` fornisce `OmfOrderHistoryService` e, separatamente, `OrderHistoryFacade` con `useClass: OmfOrderHistoryService`: i due token producono istanze diverse, quindi chi inietta `OmfOrderHistoryService` per estenderlo non riceve l'oggetto usato come facade. Resta anche l'istanza core di `OrderHistoryService` (lo stato è comunque nello store NgRx). Con `useExisting` ce ne sarebbe una sola (integration-libs/omf/order/omf-order.module.ts:L17-L23, feature-libs/order/core/facade/facade-providers.ts:L33-L37).

6. `getQueryParams` **non è un metodo proxy.** Non è nella lista `methods` della `facadeFactory` di `OrderHistoryFacade`: chiamato sul proxy prima del caricamento della feature non esisterebbe; OMF funziona perché lo storico ordini vive nel chunk order (feature-libs/order/root/facade/order-history.facade.ts:L22-L40, feature-libs/order/root/facade/order-history.facade.ts:L148-L148).
7. **Deep link al dettaglio OMF senza guid.** `getOrderGuid` cerca il guid nello stato della LISTA ordini: aprendo direttamente l'URL del dettaglio senza `?guid` e senza lista caricata, l'header non viene inviato (integration-libs/omf/order/occ-omf-order-history.adapter.ts:L31-L53).
8. **CPQ: lettura one-shot del flag.** `isFlagQuote` è letto una volta alla costruzione della riga, mentre il flag è impostato dall'heading in una subscription; l'esito dipende dall'ordine di creazione dei componenti. `CpqQuoteService` è inoltre uno stato globale condiviso fra tutte le tabelle (feature-libs/cart/base/components/cart-shared/cart-item-list-row/cart-item-list-row.component.ts:L49-L49, integration-libs/cpq-quote/cpq-quote-discount/components/cpq-quote-heading/cpq-quote-heading.component.ts:L63-L63). DA VERIFICARE a runtime.
9. **CPQ: subscription persa.** `CpqQuoteDiscountComponent` sovrascrive `this.subscription` in `ngOnInit`, perdendo la subscription a `isFlag$` creata nel costruttore (leak) (integration-libs/cpq-quote/cpq-quote-discount/components/cpq-quote-discount-tbody/cpq-quote.component.ts:L35-L44).
10. **CPQ: locale fisso.** I prezzi scontati sono formattati con `'en-US'` ignorando la lingua attiva (integration-libs/cpq-quote/cpq-quote-discount/components/cpq-quote-discount-tbody/cpq-quote.component.html:L18-L18).
11. **s4-service: pipe mai sottoscritta.** `S4ServiceOrderDetailActionsComponent.ngOnInit` crea `this.order$.pipe(tap(...))` senza `subscribe`: `displayServiceMessage` non viene mai eseguito (integration-libs/s4-service/order/components/s4-service-order-detail-actions/s4-service-order-detail-actions.component.ts:L56-L58).
12. **s4-service: dipendenza dal formato di** `toLocaleString()`**.** `getServiceDetailsCard` divide la stringa su `','` e chiama `.trim()` sul secondo pezzo: in locali senza virgola `split(',')[1]` è `undefined` → TypeError (integration-libs/s4-service/checkout/components/checkout-review-submit/service-checkout-review-submit.component.ts:L141-L145, integration-libs/s4-service/order/components/order-summary/service-details-card.component.ts:L70-L74).
13. `@Optional()` **inefficace.** Il decoratore su una proprietà inizializzata con `inject(OutletContextData)` non ha effetto: `inject` senza `{ optional: true }` lancia se il token manca (integration-libs/s4-service/order/components/order-summary/service-details-card.component.ts:L29-L29).
14. **Subscription annidate non gestite** in `CheckoutServiceDetailsComponent` e `RescheduleServiceOrderComponent` (integration-libs/s4-service/checkout/components/checkout-service-details/checkout-service-details.component.ts:L98-L105, integration-libs/s4-service/order/components/reschedule-service-order/reschedule-service-order.component.ts:L117-L124).
15. **Errori cancel non normalizzati.** `OccCancelServiceOrderAdapter` non usa `tryNormalizeHttpError`, a differenza degli altri adapter (integration-libs/s4-service/order/occ/adapters/occ-cancel-service-order.adapter.ts:L31-L31).
16. **Facade s4-service order senza factory.** Iniettare `CancelServiceOrderFacade`/`RescheduleServiceOrderFacade` fuori dal chunk order fallisce (integration-libs/s4-service/root/facade/cancel-service-order.facade.ts:L12-L15).
17. **Feature** `s4-service` **vuota.** La feature lazy registrata nell'app non porta codice; il lavoro vero è nei wrapper checkout/order (integration-libs/s4-service/s4-service.module.ts:L9-L12).
18. **Stili s4-service.** L'allowlist SCSS non include `cx-reschedule-service-order` né le detail actions (integration-libs/s4-service/_index.scss:L5-L6). Vedi 38 — Stili.
19. **Command eager in punchout.** I Command sono eseguiti subito (`execute` fa `commands$.next`): chiamate senza `subscribe`, come `endPunchoutSession()` nell'error handler della requisition, vengono comunque

eseguite (core-libs/core/src/util/command-query/command.service.ts:L126-L131, integration-libs/punchout/components/punchout-requisition/punchout-requisition.component.ts:L50-L52).

20. **Cache di sessione mai azzerata.** `cachedPunchoutSessionResponse` vive per tutta la vita del `PunchoutService` e non viene mai resettata, nemmeno a fine sessione (integration-libs/punchout/core/facade/punchout.service.ts:L57-L57, integration-libs/punchout/core/facade/punchout.service.ts:L254-L257). DA VERIFICARE se il servizio viene ricreato tra due sessioni nella stessa tab.
21. **Il guard punchout fallisce "aperto".** `catchError(() => of(undefined))` inghiotte ogni errore e in quel caso non applica restrizioni (integration-libs/punchout/root/guards/punchout-navigation.guard.ts:L129-L129).
22. `allowedUrls` **per sottostringa.** `isAllowedUrls` usa `includes` sul path relativo: un URL ammesso parziale autorizza qualsiasi path che lo contenga (integration-libs/punchout/root/guards/punchout-navigation.guard.ts:L77-L81).
23. **Interceptor su ogni richiesta.** `PunchoutCartInterceptor` legge lo stato su OGNI richiesta HTTP (anche non-OCC) e confronta con `url.includes('/carts/{id}')` (integration-libs/punchout/root/interceptors/punchout-cart.interceptor.ts:L31-L46).
24. **Refuso nel selettore** `cx-punchout-requsition` (integration-libs/punchout/components/punchout-requisition/punchout-requisition.component.ts:L26-L26).
25. **EPD: servizi** `providedIn: 'root'` **che iniettano** `ElementRef`**/**`ChangeDetectorRef`**.** `VisualPickingTabService`, `VisualViewerService` e altri funzionano solo perché i componenti li ridichiarano in `providers` (integration-libs/epd-visualization/components/visual-picking/visual-picking-tab/visual-picking-tab.service.ts:L30-L39, integration-libs/epd-visualization/components/visual-picking/visual-picking-tab/visual-picking-tab.component.ts:L27-L27, integration-libs/epd-visualization/components/visual-viewer/visual-viewer.component.ts:L30-L30).
26. **EPD: id dello script e callback globale.** Lo script UI5 riceve prima l'id `ui5bootstrap`, poi viene sovrascritto con `sap-ui-bootstrap`; la callback è una proprietà globale su `document` (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1118-L1133).
27. **EPD: accesso diretto a** `document`**.** `getCSSPropertyValue` usa il global `document` e `cx-storefront` invece di `WindowRef` (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1391-L1396).
28. **EPD:** `useSecureConnection: false` nel `ContentResource` (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1561-L1561).
29. **EPD: config mancante non bloccante.** Senza `apis`/`ui5` il validator dà solo un warning in dev. Adapter e viewer fanno cast non nulli: se manca l'oggetto si ottiene un `TypeError` su `.baseUrl`/`.bootstrapUrl`; se manca solo la proprietà, un URL `undefined/vis/public/...` (integration-libs/epd-visualization/epd-visualization-api/adapters/storage-v1/storage-v1.adapter.ts:L49-L56, integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1108-L1108, integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1138-L1138).
30. **EPD: documentazione invertita** in `SelectionDisplayMode` (Highlight descritto come outline e viceversa) (integration-libs/epd-visualization/components/visual-viewer/models/selection-display-mode.ts:L12-L22).
31. **EPD: config letta nel costruttore.** `SceneNodeToProductLookupService` legge `usageIds` nel costruttore con cast: se la config non è completa al momento dell'istanza fallisce (integration-libs/epd-visualization/core/services/scene-node-to-product-lookup/scene-node-to-product-lookup.service.ts:L35-L43).
32. **Collection punchout con factory sbagliata.** Lo schematic `add` punta a `./add-punchout/index#addCustomerTicketingFeatures`, funzione che `add-punchout/index.ts` non esporta (copia da customer-ticketing): solo `ng-add` funziona (integration-libs/punchout/schematics/collection.json:L12-L16, integration-libs/punchout/schematics/add-punchout/index.ts:L25-L25).

33. **Collection s4om con factory mancante.** `add-spartacus-library` punta a `./add-library/index#addSpartacusLibrary`, ma `integration-libs/s4om/schematics/` contiene solo `add-s4om`, `collection.json` e `constants.ts` (integration-libs/s4om/schematics/collection.json:L12-L17).
34. **Due entry file in s4om.** `index.ts` e `public_api.ts` esportano lo stesso modulo, ma sia ng-packagr sia il path mapping `@spartacus/s4om` usano solo `public_api.ts`: `index.ts` non è referenziato (integration-libs/s4om/index.ts:L7-L7, integration-libs/s4om/public_api.ts:L10-L10, integration-libs/s4om/ng-package.json:L4-L6, tsconfig.json:L612-L612).

---

10. Come fare debug

- **Quale implementazione ha vinto?** Nel chunk lazy, da un componente della feature (es. order history) ispezionare l'injector con Angular DevTools e verificare che `OrderHistoryFacade` sia un `OmfOrderHistoryService` e `OrderHistoryAdapter` un `OccOmfOrderHistoryAdapter` (integration-libs/omf/order/omf-order.module.ts:L19-L23). Lo stesso per `CheckoutStepsSetGuard` → `CheckoutServiceOrderStepsSetGuard` (integration-libs/s4-service/checkout/components/s4-service-checkout-component.module.ts:L20-L25) e per `CartItemListComponentService` → `CpqQuoteSharedService` (integration-libs/cpq-quote/cpq-quote-discount/cpq-discount.module.ts:L41-L41). Se vince l'originale, controllare l'ordine nel wrapper (§3.1).
- **OMF: header assente.** In DevTools Network, sulla GET del dettaglio ordine, cercare l'header con il nome configurato (minuscolo). Se manca: verificare `?guid=` nell'URL (§3.2 passo 4) o che la lista ordini sia nello store; in dev mode cercare in console il warning *"There is no guidHttpHeaderName configured in OMF configuration"* (integration-libs/omf/order/occ-omf-order-history.adapter.ts:L57-L61).
- **S4OM: link prodotto disabilitato in carrello.** Controllare `product.stock.stockLevelStatus` nella risposta OCC: `notOrderable` → fuori catalogo (integration-libs/s4om/root/services/s4om-product-catalog.service.ts:L28-L36).
- **CPQ: colonna sconto non visibile.** Verificare che le entry abbiano `cpqDiscounts` non vuoto e inserire un breakpoint su `setFlag` in `CpqQuoteHeadingComponent` e su `showBasePriceWithDiscount` in `CpqQuoteSharedService` per osservare l'ordine (§9.8) (integration-libs/cpq-quote/cpq-quote-discount/components/cpq-quote-heading/cpq-quote-heading.component.ts:L63-L63, integration-libs/cpq-quote/cpq-quote-discount/cpq-qute-shared.service.ts:L21-L23).
- **s4-service: step mancante.** Lo step `serviceDetails` si vede solo se il carrello contiene entry con `productTypes === SERVICE` (integration-libs/s4-service/checkout/core/facade/checkout-service-details.service.ts:L99-L131) e se nessun altro ha ri-sostituito `CheckoutConfig` (§9.1). Dopo il submit verificare la `PATCH .../serviceScheduleSlot` e la successiva GET dei dettagli checkout con `servicedAt` nei fields (integration-libs/s4-service/checkout/occ/config/default-occ-checkout-s4-service-config.ts:L10-L25).
- **s4-service: componente CMS non renderizzato.** Controllare in config finale `featureModules.checkout.cmsComponents` / `featureModules.order.cmsComponents` (§9.3).
- **Punchout.** Ispezionare `localStorage` (chiave `spartacus⁉️⁉️punchout`, solo il session id; vedi §3.8) (integration-libs/punchout/root/services/punchout-state-persistence.service.ts:L23-L36); la classe `cxPunchoutSessionActive` sull'elemento root; l'header `punchoutsid` sulle chiamate `/carts/{id}` (integration-libs/punchout/root/interceptors/punchout-cart.interceptor.ts:L34-L44). Per redirect inattesi, breakpoint in `PunchoutNavigationGuard.canActivate` su `cxRoute` e `punchoutOperation` (integration-libs/punchout/root/guards/punchout-navigation.guard.ts:L40-L50). Per il refresh token, verificare il valore del toggle `enableExpiredRefreshTokenHandlers` (§3.10).

- **EPD.** Verificare in `<head>` la presenza dello script `sap-ui-bootstrap` e `window.sap`; in dev mode cercare i warning del config validator (core-libs/core/src/config/config-validator/config-validator.ts:L42-L47); controllare le chiamate `.../vis/public/visualization/v1/lookup/visualization` e `.../storage/v1/scenes/{id}/nodes` (integration-libs/epd-visualization/epd-visualization-api/adapters/visualization-v1/visualization-v1.adapter.ts:L50-L68, integration-libs/epd-visualization/epd-visualization-api/adapters/storage-v1/storage-v1.adapter.ts:L49-L108). In SSR il viewer non fa nulla per costruzione (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L86-L88).
- **Backend.** Quali addon Commerce espongano `serviceOrder/*`, `punchout/sessions/*`, `cpqDiscounts`, `scheduleLines`, `guid` non è deducibile dal frontend. `DA VERIFICARE` nella documentazione backend.

---

11. Domande di autoverifica

1. **Perché `OmfOrderModule` è importato in `OrderWrapperModule` e non nell'AppModule?** Perché sostituisce `OrderHistoryAdapter` e `OrderHistoryFacade`, i cui binding originali sono forniti dal chunk lazy order; l'override deve stare nello stesso injector e dopo `OrderModule` (projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L14-L27, integration-libs/omf/order/omf-order.module.ts:L15-L26).
2. **Da dove prende OMF il guid quando l'URL del dettaglio non ha `?guid`?** Dalla lista ordini nello store NgRx (`OrderSelectors.getOrdersState`), cercando l'ordine per `code` (integration-libs/omf/order/occ-omf-order-history.adapter.ts:L31-L53).
3. **Cosa cambia S4OM nel concetto di "prodotto in catalogo"?** Un prodotto con `stock.stockLevelStatus === 'notOrderable'` non è considerato in catalogo; senza status lo è (integration-libs/s4om/root/services/s4om-product-catalog.service.ts:L23-L37), contro il `!!product` del core (core-libs/core/src/product/services/product-catalog.service.ts:L20-L22).
4. **Come fa CPQ a nascondere il prezzo base standard nelle righe del carrello?** Sostituisce `CartItemListComponentService` con `CpqQuoteSharedService`, il cui `showBasePriceWithDiscount()` ritorna il flag impostato dall'heading a `!hasDiscounts` (integration-libs/cpq-quote/cpq-quote-discount/cpq-discount.module.ts:L41-L41, integration-libs/cpq-quote/cpq-quote-discount/components/cpq-quote-heading/cpq-quote-heading.component.ts:L55-L63).
5. **Perché con s4-service attivo un `provideConfig({ checkout: { steps: [...] } })` può non avere effetto?** Perché `S4ServiceRootModule` fornisce `CheckoutConfig` con `useValue`, scavalcando il normale `useExisting: Config` (integration-libs/s4-service/root/s4-service-root.module.ts:L75-L75, feature-libs/checkout/base/root/config/checkout-config.ts:L18-L22).
6. **Come viene aggiunto `SERVICE_DETAILS` a un enum definito in un'altra libreria?** Con una module augmentation per i tipi e con un'assegnazione `(CheckoutStepType as any)['SERVICE_DETAILS'] = 'serviceDetails'` per il runtime (integration-libs/s4-service/root/model/augmented-types.model.ts:L38-L47).
7. **Perché s4-service ripete l'intera lista `CHECKOUT_B2B_CMS_COMPONENTS` invece di aggiungere solo `CheckoutServiceDetails`?** Perché `deepMerge` sostituisce gli array: l'ultima `cmsComponents` fusa vince (integration-libs/s4-service/root/s4-service-root.module.ts:L31-L34, core-libs/core/src/config/utils/deep-merge.ts:L36-L45).
8. **Cosa succede dopo che lo slot di servizio è stato salvato con successo?** Il Command emette `CheckoutServiceDetailsSetEvent`; il listener lo trasforma in `CheckoutQueryResetEvent`, che ricarica i dettagli checkout (con `servicedAt` nei fields) (integration-libs/s4-service/checkout/core/facade/checkout-service-details.service.ts:L48-L58, integration-libs/s4-service/root/events/checkout-service-

details-event.listener.ts:L23-L29, feature-libs/checkout/base/core/facade/checkout-query.service.ts:L38-L39).

9. **Come gestisce Punchout un refresh token scaduto quando** `enableExpiredRefreshTokenHandlers` **è attivo, e perché non sovrascrive più** `AuthHttpHeaderService`**?** Contribuisce `PunchoutExpiredRefreshTokenHandler` a `EXPIRED_REFRESH_TOKEN_HANDLERS`; il core interroga gli handler in sequenza e usa il fallback solo se nessuno gestisce il caso. Si evita così il conflitto con l'override ASM (integration-libs/punchout/root/punchout.root.module.ts:L67-L71, core-libs/core/src/auth/user-auth/services/auth-http-header.service.ts:L265-L285, core-libs/core/src/auth/user-auth/services/auth-http-header.service.ts:L311-L316).
10. **Che cosa persiste Punchout nello storage del browser e perché un id assente diventa** `''`**?** Solo il `punchoutSessionId`, in `localStorage` sotto la chiave `spartacus⚿⚿punchout` (key `punchout` con prefisso e contesto vuoto aggiunti da `StatePersistenceService`, core-libs/core/src/state/services/state-persistence.service.ts:L124-L130); dopo l'avvio un id assente è scritto come `''` perché `StatePersistenceService` non permette di cancellare la chiave (integration-libs/punchout/root/services/punchout-state-persistence.service.ts:L23-L53).
11. **Perché il visual viewer EPD non fa nulla durante l'SSR?** Il costruttore di `VisualViewerService` esce subito se `!windowRef.isBrowser()`, e `loadVisualization` lato server ritorna un `UnexpectedError`; UI5 è caricato iniettando uno script nel DOM del browser (integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L86-L88, integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1032-L1092, integration-libs/epd-visualization/components/visual-viewer/visual-viewer.service.ts:L1105-L1140).

TAVOLA 36.1 **4.1 Dove vive ogni override (injector root vs chunk lazy)**

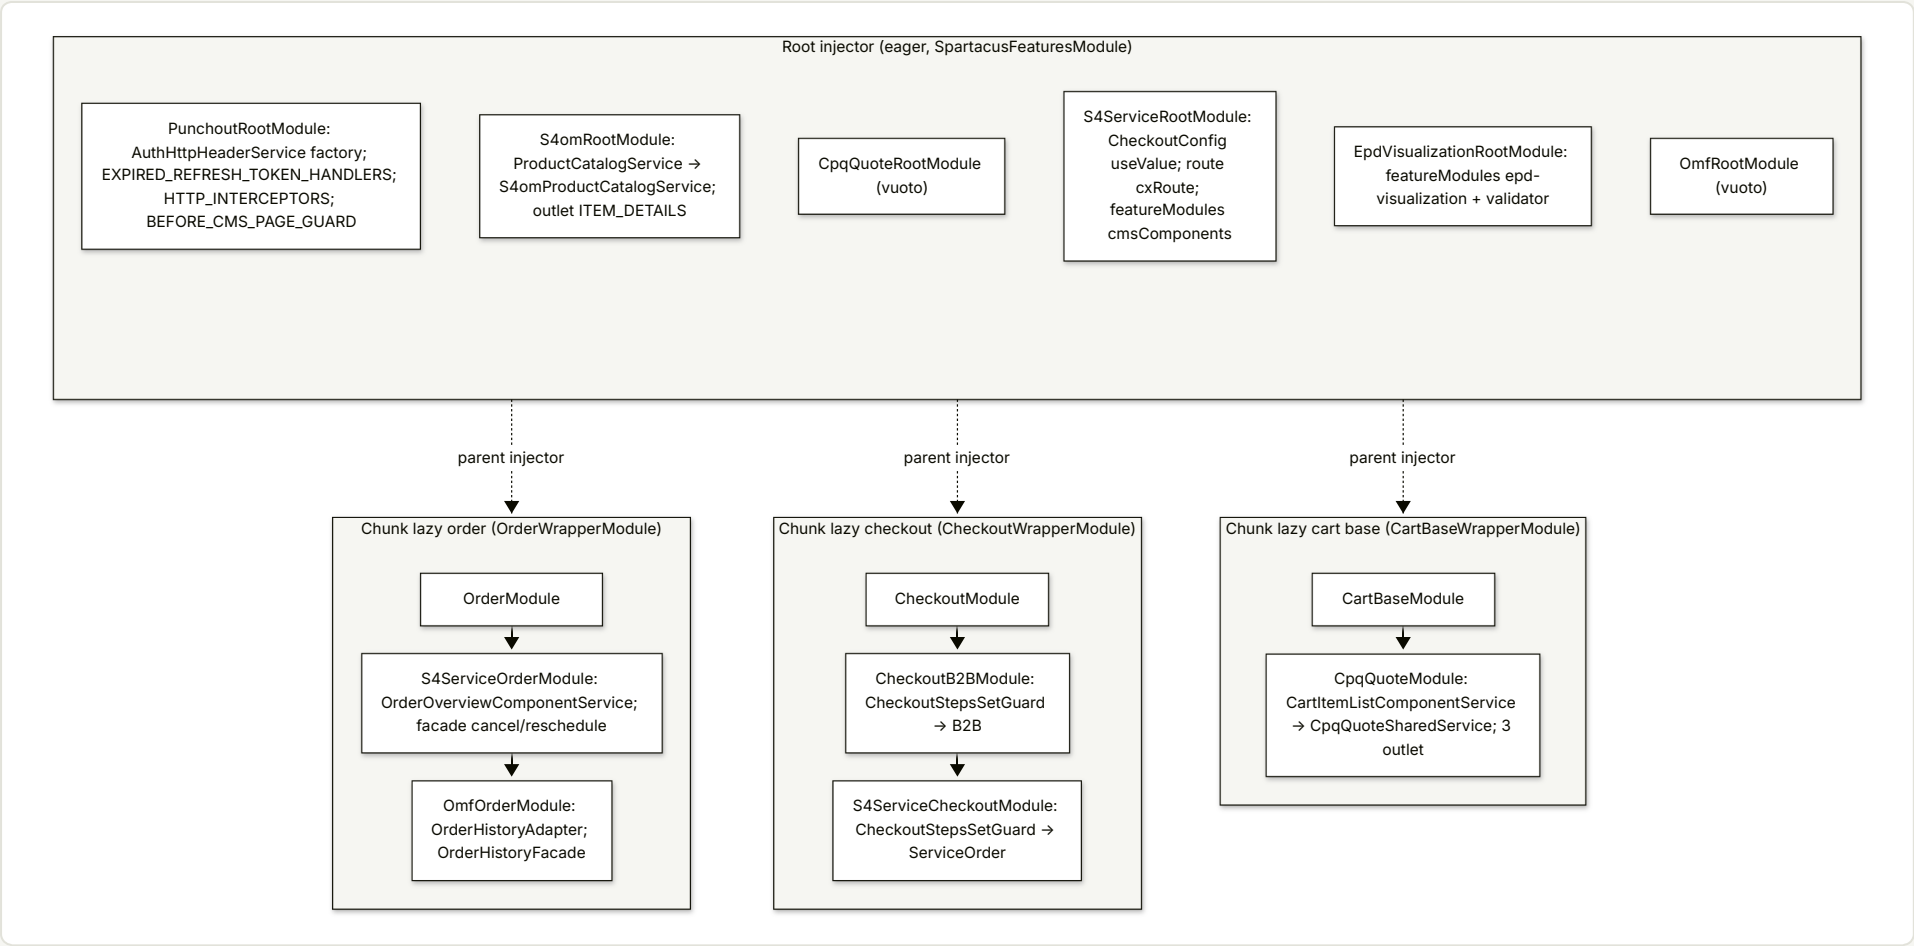

TAVOLA 36.2 **4.2 OMF: dal link dello storico al dettaglio con header guid**

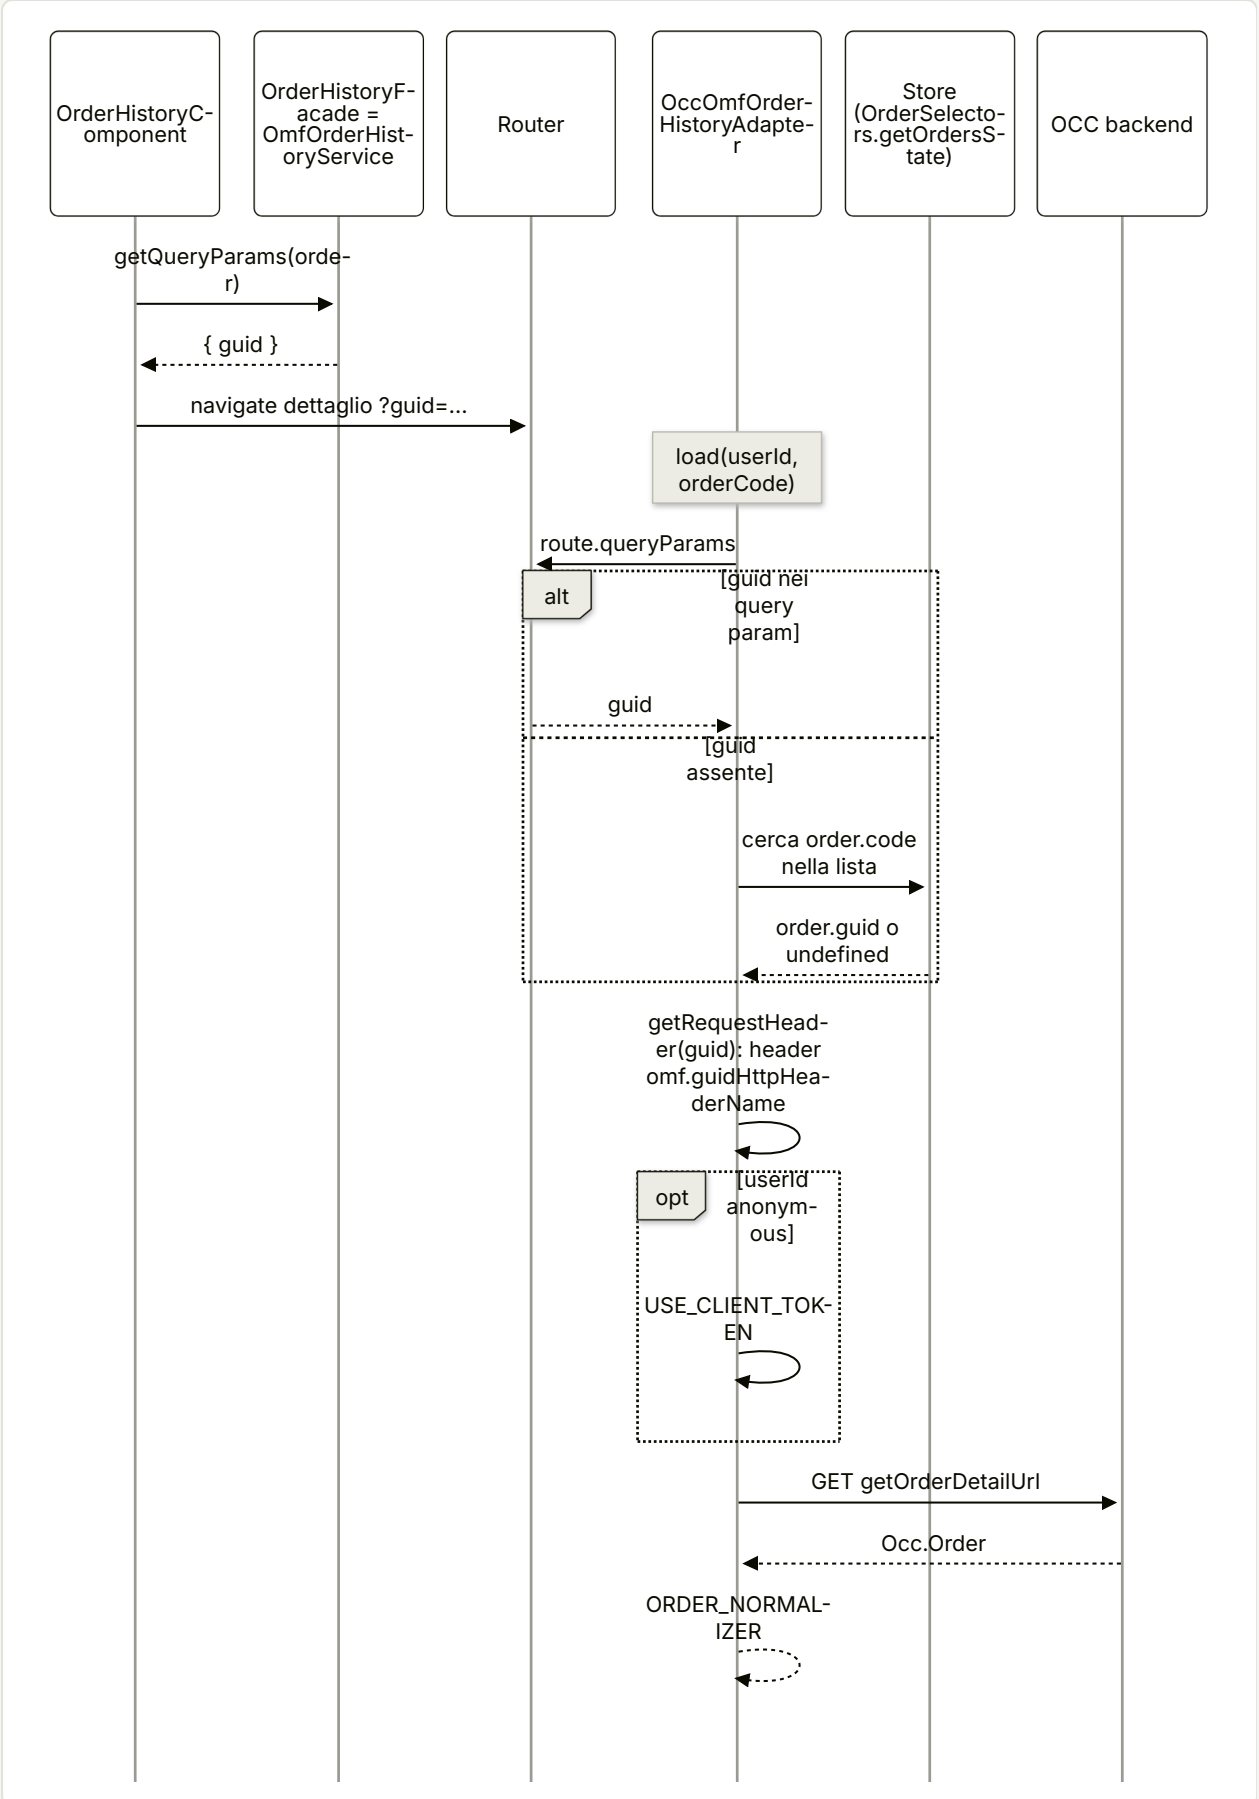

TAVOLA 36.3 **4.3 S/4 Service: step "service details" del checkout**

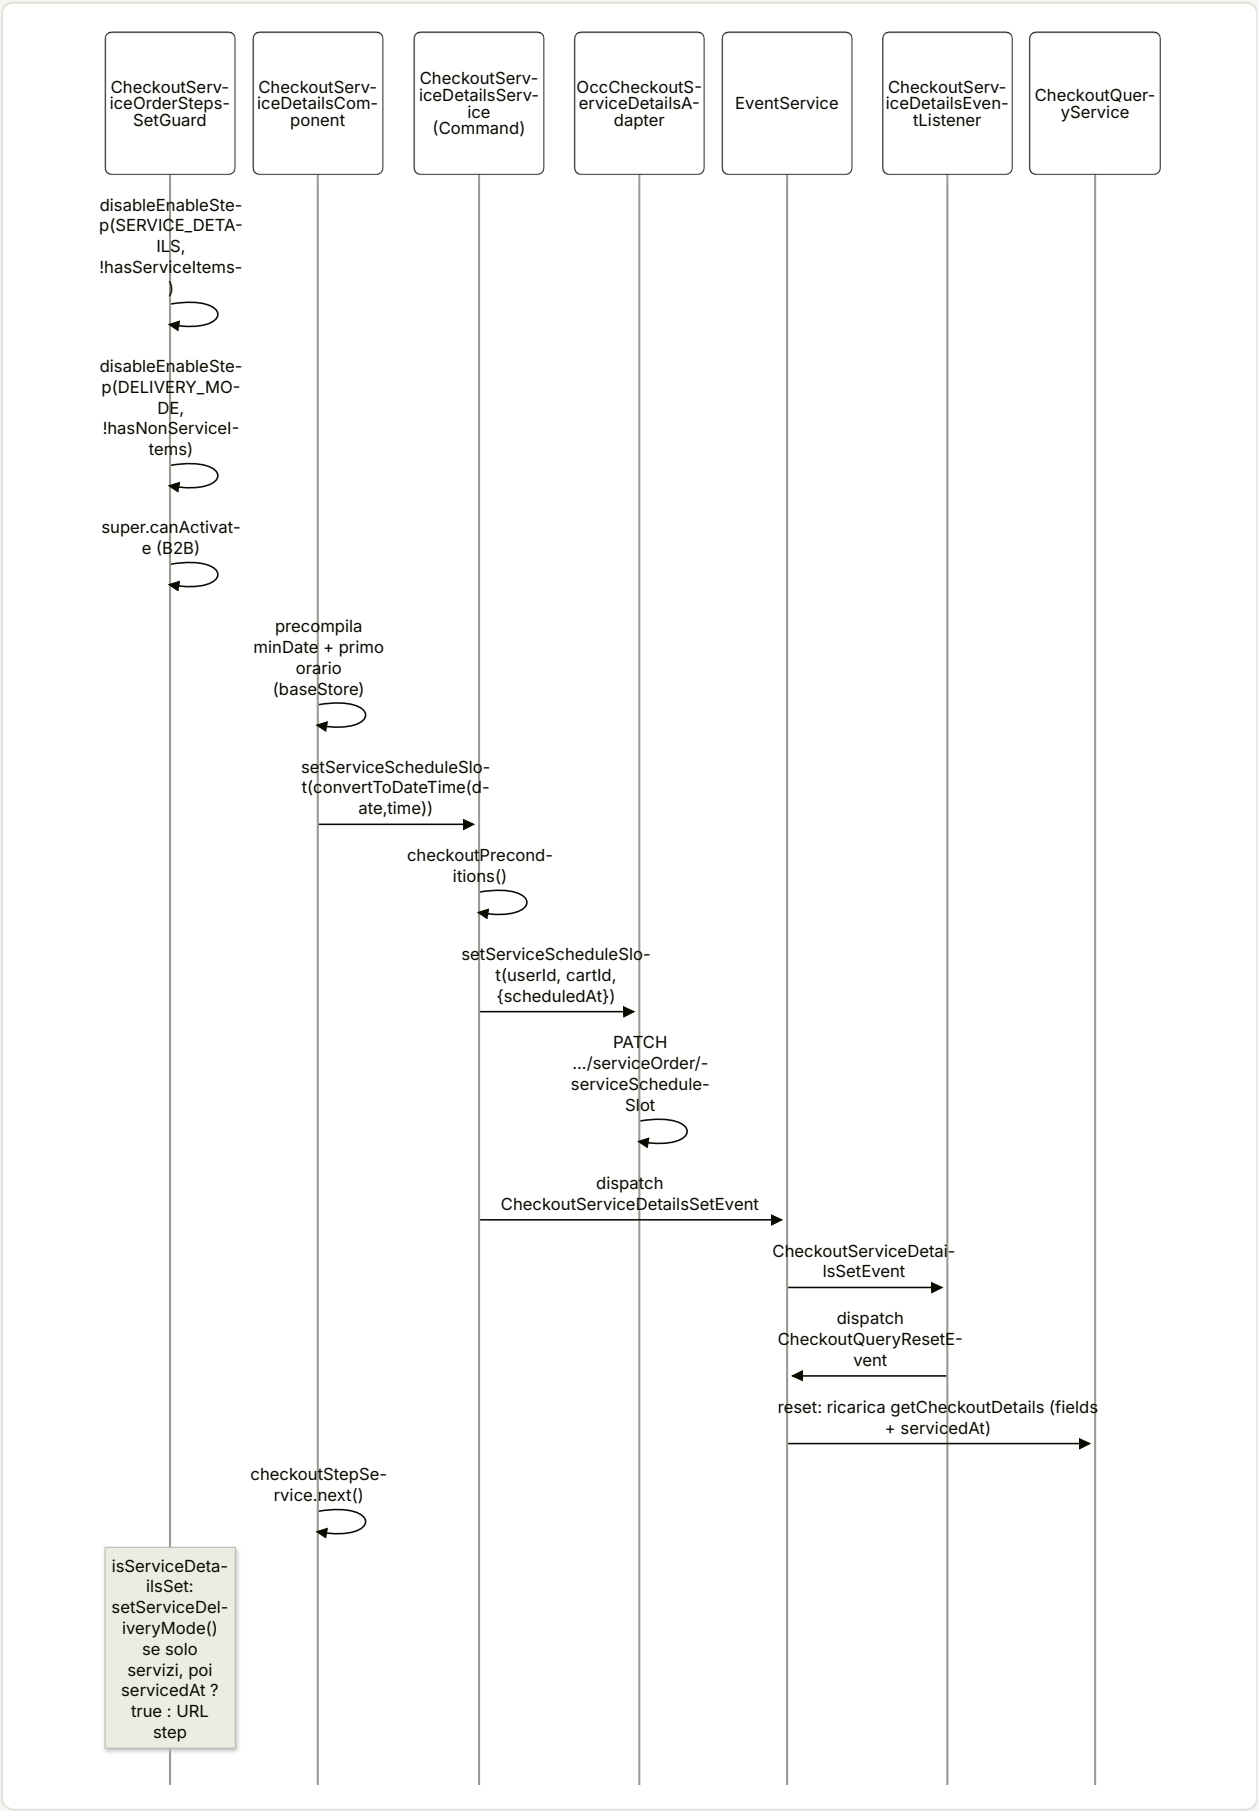

TAVOLA 36.4 **4.4 Punchout: ciclo di vita della sessione**

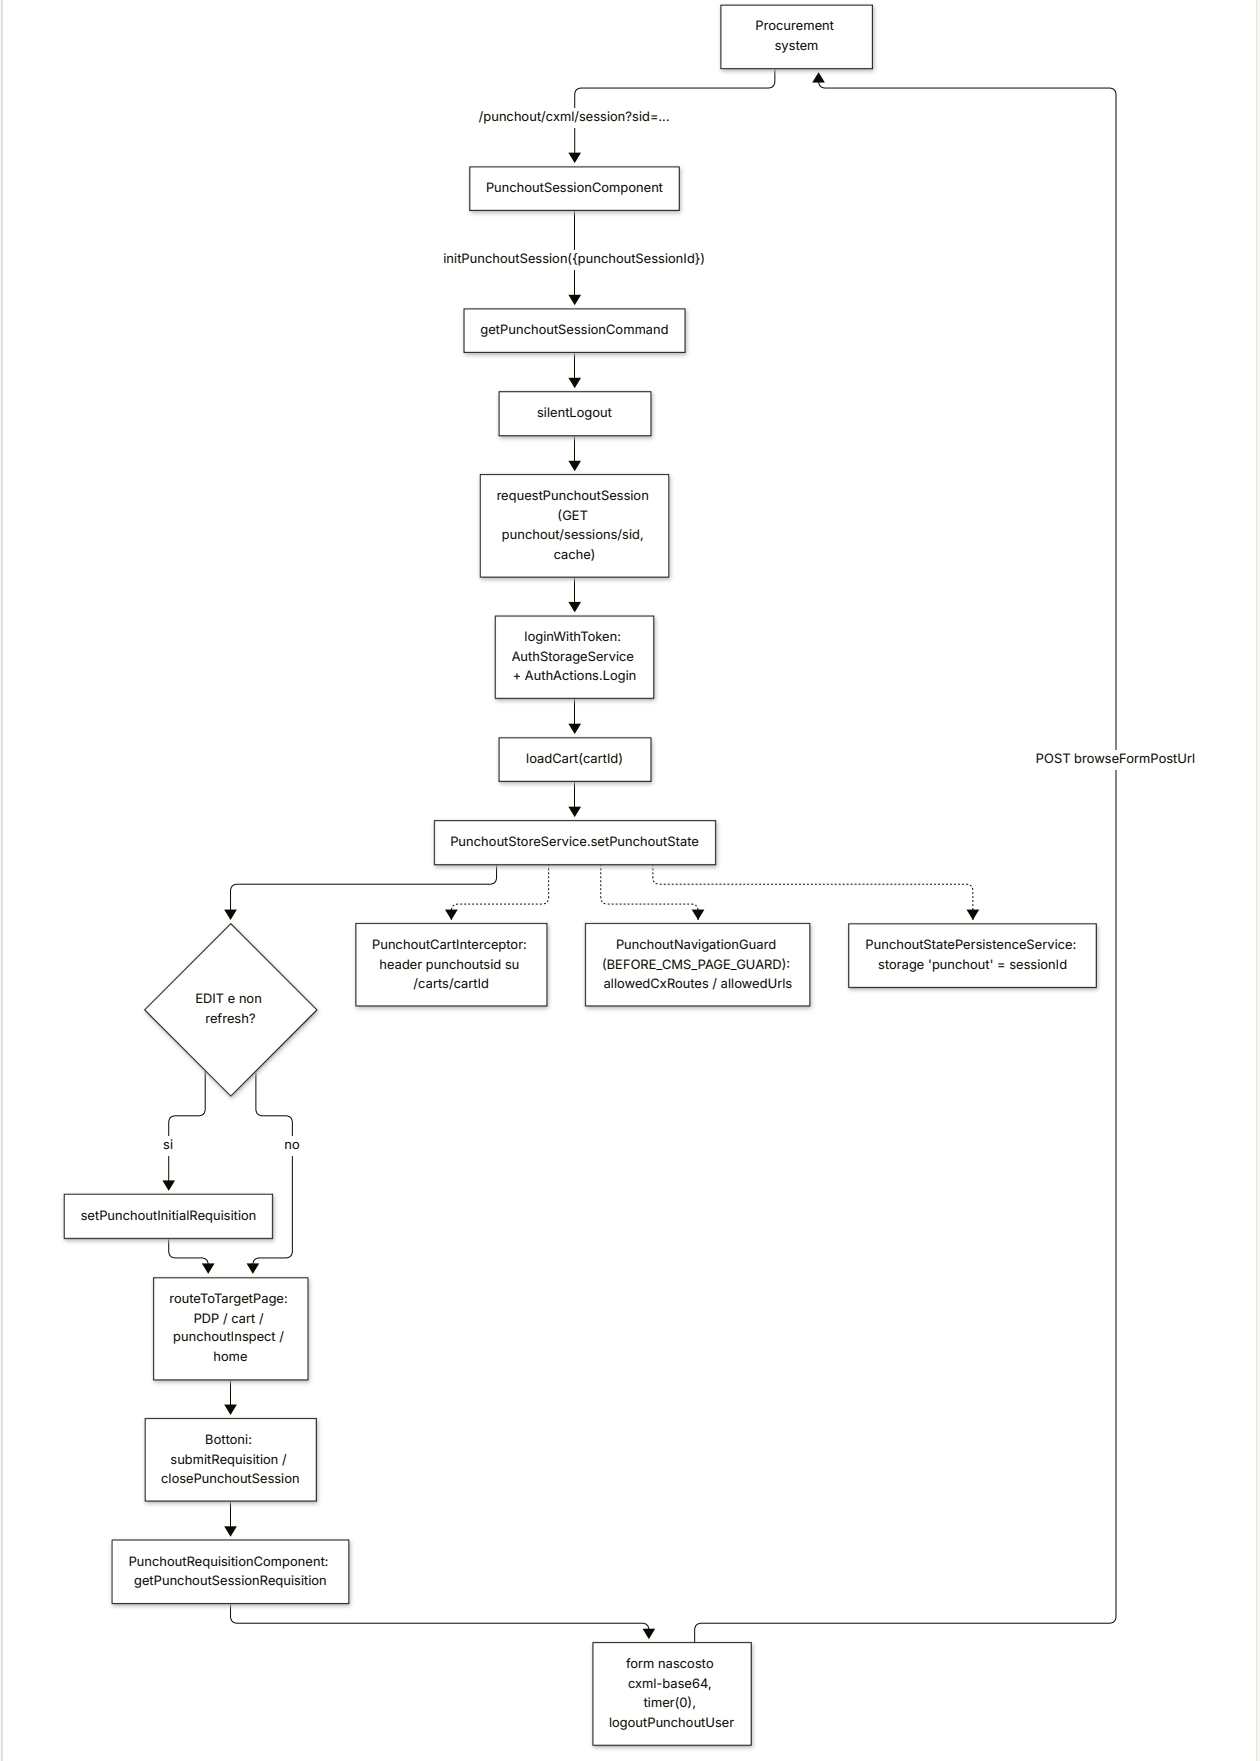

TAVOLA 36.5 **4.6 EPD: visual picking**

1. A cosa serve e perché esiste

Spartacus non usa il sistema i18n di Angular (`@angular/localize`, `$localize`, build per lingua). Tutti i testi dello storefront passano a runtime da **chiavi di traduzione** come `'common.back'` o `'orderDetails.orderNumber'`, risolte da un servizio astratto, `TranslationService`. L'implementazione di default è un adattatore su **i18next**. Questa scelta ha tre conseguenze, che ritornano in tutto il capitolo:

1. **Un solo bundle per tutte le lingue.** La lingua attiva è quella del site context (`LanguageService.getActive()`, core-libs/core/src/site-context/facade/language.service.ts:L49-L54), e il cambio lingua avviene senza ricaricare la pagina: `I18nextInitializer` si sottoscrive alla lingua attiva e chiama `i18next.changeLanguage(lang)` (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L100-L106).
2. **Le traduzioni sono dati di configurazione.** Si forniscono con `provideConfig({ i18n: { resources, chunks, ... } })` e si fondono con il deep merge della configurazione globale (vedi 11 — Configurazione). `I18nConfig` è un alias del `Config` globale (core-libs/core/src/i18n/config/i18n-config.ts:L14-L18), esteso tramite module augmentation (core-libs/core/src/i18n/config/i18n-config.ts:L94-L96).
3. **Le traduzioni sono divise in *chunk*.** Un chunk è un namespace i18next che raggruppa più "namespace logici" (la prima parte della chiave, prima del punto). La mappa `i18n.chunks` dice quali namespace stanno in quale chunk (core-libs/core/src/i18n/config/i18n-config.ts:L85-L90). Un chunk si può caricare in modo eager (`i18n.resources`) oppure lazy tramite un *backend* (`i18n.backend.loadPath` per HTTP, `i18n.backend.loader` per un `import()` dinamico) (core-libs/core/src/i18n/config/i18n-config.ts:L30-L78).

Accanto alle traduzioni testuali ci sono due pipe di formattazione legate alla lingua attiva: `cxDate` (`CxDatePipe`, estende il `DatePipe` di Angular) e `cxNumeric` (`CxNumericPipe`, estende `DecimalPipe`). Entrambe passano ad Angular come locale la lingua del site context (core-libs/core/src/i18n/date.pipe.ts:L25-L27, core-libs/core/src/i18n/numeric.pipe.ts:L22-L24).

Le traduzioni "di prodotto" stanno nel pacchetto `@spartacus/assets` (`core-libs/assets/`) per il core, e nel secondary entry point `assets` di ogni feature lib (es. feature-libs/order/assets/public_api.ts:L7-L7). Il pacchetto assets ha anche alcuni script di generazione (JSON per il lazy loading, `.properties` per i traduttori), di cui vedremo che due sono rimasti indietro rispetto al codice.

Infine c'è un aspetto meno visibile ma fondamentale: in SSR ogni richiesta deve avere **la propria istanza di i18next**, altrimenti richieste concorrenti in lingue diverse si pesterebbero i piedi. Per questo l'istanza non è l'import globale di `i18next` ma un `InjectionToken` con factory `i18next.createInstance()` (core-libs/core/src/i18n/i18next/i18next-instance.ts:L10-L22).

Capitoli collegati: il site context e `LanguageService` sono in 13 — Site context e theme; `CONFIG_INITIALIZER` e `ConfigInitializerService` in 10 — Bootstrap e inizializzazione e 11 — Configurazione; il precaricamento dei chunk dal CMS in 16 — Rendering CMS; il `LoggerService` in 41 — Errori e global message.

2. Mappa dei file

PATH	RUOLO
core-libs/core/src/i18n/config/i18n-config.ts	classe astratta `I18nConfig` (`useExisting: Config`) e augmentation di `Config`
core-libs/core/src/i18n/config/default-i18n-config.ts	`defaultI18nConfig`: `fallbackLang: undefined`, `debug: false` (non pubblico)

scripts/i18n/validate-translations-json-files.ts	validatore dei JSON eseguito da build:libs

3. Come funziona passo per passo

3.1 Registrazione dei provider

BaseCoreModule importa I18nModule.forRoot() (core-libs/core/src/base-core.module.ts:L33-L33), quindi ogni app Spartacus ha i provider i18n senza doverli dichiarare. forRoot() registra quattro cose (core-libs/core/src/i18n/i18n.module.ts:L41-L56):

- la config di default defaultI18nConfig, con fallbackLang: undefined e debug: false (core-libs/core/src/i18n/config/default-i18n-config.ts:L9-L14);
- l'alias TranslationService → I18nextTranslationService con useExisting (core-libs/core/src/i18n/i18n.module.ts:L46-L46);
- i18nextProviders, cioè un APP_INITIALIZER più i provider dei backend (core-libs/core/src/i18n/i18next/i18next-providers.ts:L13-L28);
- un CONFIG_INITIALIZER multi la cui factory è initI18nConfig (core-libs/core/src/i18n/i18n.module.ts:L48-L53).

I18nModule senza forRoot() importa ed esporta solo le tre pipe standalone TranslatePipe, CxDatePipe, CxNumericPipe (core-libs/core/src/i18n/i18n.module.ts:L36-L39): è quello che i moduli feature importano per usare cxTranslate nei template.

3.2 Il fallback dinamico: `I18nConfigInitializer`

`initI18nConfig` decide se serve calcolare la lingua di fallback a runtime: se `config.i18n.fallbackLang` è diverso da `undefined` (anche `false`) restituisce `null`, altrimenti restituisce l'initializer (core-libs/core/src/i18n/i18n.module.ts:L23-L34). `ConfigInitializerService.initialize` salta semplicemente gli initializer `null` (core-libs/core/src/config/config-initializer/config-initializer.service.ts:L140-L143).

Se l'initializer è attivo, dichiara lo scope `i18n.fallbackLang` (core-libs/core/src/i18n/config/i18n-config-initializer.ts:L14-L17) e il suo `resolveConfig` aspetta che lo scope `context.language` sia stabile, poi usa il primo elemento dell'array come fallback (core-libs/core/src/i18n/config/i18n-config-initializer.ts:L24-L33). Lo scope `context` è prodotto da `SiteContextConfigInitializer` (core-libs/core/src/site-context/config/config-loader/site-context-config-initializer.ts:L26-L26). `getStable(...scopes)` emette subito se il config è già stabile, altrimenti aspetta che nessuno scope in corso si sovrapponga a quelli richiesti (core-libs/core/src/config/config-initializer/config-initializer.service.ts:L58-L70). Il risultato viene unito con deep merge sia nel root config sia nel config globale, poi lo scope viene chiuso (core-libs/core/src/config/config-initializer/config-initializer.service.ts:L158-L166).

In pratica: se non configuri `fallbackLang`, la lingua di fallback diventa la lingua di default del sito (la prima di `context.language`), che può arrivare anche dal backend tramite il caricamento dinamico del site context.

3.3 Inizializzazione di i18next (`APP_INITIALIZER`)

L'`APP_INITIALIZER` di `i18nextProviders` aspetta `getStable('i18n')` (cioè anche il fallback dinamico appena descritto) e poi chiama `I18nextInitializer.initialize()` (core-libs/core/src/i18n/i18next/i18next-providers.ts:L14-L25).

`initialize()` costruisce le opzioni con `getI18nextConfig()`, registra il plugin logger e chiama `init(config, callback)` (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L36-L44). Le opzioni base sono (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L49-L61):

- `ns: []`: nessun namespace precaricato (il default di i18next sarebbe `['translation']`, deps:i18next-25.7.4/package/dist/esm/i18next.js:L1619-L1622);
- `fallbackLng` e `debug` dalla config;
- `interpolation.escapeValue: false` e `interpolation.skipOnVariables: false`, entrambi `true` per default in i18next (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1665-L1676);
- `showSupportNotice: false`, con un `@ts-ignore` perché l'opzione non esiste nei tipi della versione installata (in i18next 25.7.4 la stringa `showSupportNotice` non compare nel sorgente ESM).

Se esiste `config.i18n.backend`, alle opzioni si aggiunge quanto restituito da `I18nextBackendService.initialize()` (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L63-L68), vedi §3.6.

Nel **callback** di `init`, e non come opzione `resources` di i18next, Spartacus aggiunge le risorse statiche e avvia la sincronizzazione della lingua (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L38-L43). Il commento spiega perché: passare `resources` a i18next disattiverebbe il caricamento dei chunk dal backend. Infatti in i18next `loadResources` usa il backend solo se `!this.options.resources || this.options.partialBundledLanguages` (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1853-L1857).

`addTranslationResources` itera su lingua e chunk di `config.i18n.resources` e chiama `addResourceBundle(lang, chunk, data, true, true)`, cioè con `deep` e `overwrite` (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L79-L92). Con `deep` i18next fa un `deepExtend` sul bundle esistente, dopo aver copiato i dati con `JSON.parse(JSON.stringify(...))` (deps:i18next-25.7.4/package/dist/esm/i18next.js:L369-L385).

`synchronizeLanguage` si sottoscrive una sola volta (grazie a `??`) a `LanguageService.getActive()` e chiama `changeLanguage(lang)` a ogni emissione; la subscription si chiude in `ngOnDestroy` (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L100-L110). `getActive()` filtra i valori nulli, quindi non emette finché lo store non ha una lingua attiva (core-libs/core/src/site-context/facade/language.service.ts:L49-L54).

Quando si risolve la Promise dell'`APP_INITIALIZER`? In i18next 25.7.4 il default è `initAsync: true` (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1619-L1622) e, poiché Spartacus non passa `resources`, il caricamento viene rimandato con `setTimeout(load, 0)` (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1846-L1850). Il deferred restituito da `init` si risolve in `finish`, dopo `changeLanguage(this.options.lng, finish)`: lì `isInitialized` diventa `true` e viene chiamato il callback (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1834-L1844). Spartacus non passa `lng`, quindi la lingua "vera" arriva solo con la prima emissione di `getActive()` dentro `synchronizeLanguage`. **DA VERIFICARE**: il comportamento interno di `changeLanguage(undefined)` (rilevamento lingua, uso di `fallbackLng`) non è stato letto riga per riga.

`changeLanguage` emette l'evento `languageChanged` solo dopo `loadResources`, e solo se nel frattempo non è stata richiesta un'altra lingua (`isLanguageChangingTo === lng`) (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1955-L1962).

3.4 Istanza e logger

`I18NEXT_INSTANCE` è un `InjectionToken` `providedIn: 'root'` con factory `i18next.createInstance()` (core-libs/core/src/i18n/i18next/i18next-instance.ts:L19-L22). In i18next `createInstance` costruisce un nuovo oggetto i18n (deps:i18next-25.7.4/package/dist/esm/i18next.js:L2122-L2126). Poiché in SSR ogni richiesta ha il proprio platform/root injector, ognuna riceve la propria istanza (vedi 07 — SSR, hydration e TransferState). Tutte le classi che toccano i18next la iniettano con `@Inject(I18NEXT_INSTANCE)` (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L24-L29, core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L23-L28).

`I18NEXT_LOGGER_PLUGIN` è un altro token root: la factory restituisce un modulo i18next `type: 'logger'` che inoltra `log`/`warn`/`error` al `LoggerService` (core-libs/core/src/i18n/i18next/i18next-plugins/i18next-logger-plugin.ts:L17-L40). Il logger interno di i18next scarta `log` e `warn` quando `debug` è false; `error` passa sempre (deps:i18next-25.7.4/package/dist/esm/i18next.js:L219-L231). Quindi `i18n.debug: true` serve a vedere nei log Spartacus gli eventi di caricamento.

3.5 Dalla chiave al chunk: `TranslationChunkService`

Nel costruttore, `TranslationChunkService` inverte `config.i18n.chunks` in una mappa namespace → chunk. Se un namespace compare in più chunk vince il primo, e i doppioni finiscono in `duplicates` (core-libs/core/src/i18n/translation-chunk.service.ts:L20-L33); in dev mode viene emesso un `warn` che indica quale chunk è stato usato (core-libs/core/src/i18n/translation-chunk.service.ts:L34-L36, core-libs/core/src/i18n/translation-chunk.service.ts:L51-L65).

`getChunkNameForKey(key)` prende il segmento prima del primo `.` e lo cerca nella mappa; se non lo trova usa il namespace stesso come nome del chunk (core-libs/core/src/i18n/translation-chunk.service.ts:L39-L49). Con la config di `@spartacus/assets`, per esempio, `'searchBox.placeholder'` → namespace `searchBox` → chunk `common`, perché `searchBox` è tra i namespace del chunk `common` (core-libs/assets/src/translations/translations.ts:L7-L27).

3.6 Scelta del backend

`i18nextBackendProviders` registra in multi provider, nell'ordine, `I18nextHttpBackendInitializer` e `I18nextResourcesToBackendInitializer`, entrambi con `useExisting` (core-libs/core/src/i18n/i18next/

i18next-backend/i18next-backend.providers.ts:L12-L23). `I18nextBackendService.initialize()` sceglie il vincitore con `resolveApplicable` e ne restituisce `initialize()`, oppure `{}` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-backend.service.ts:L20-L38).

- `I18nextHttpBackendInitializer.hasMatch()` è true se c'è `i18n.backend.loadPath` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L38-L40). `initialize()` registra `i18next-http-backend` e restituisce `{ backend: getBackendConfig() }` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L47-L50). La config usa come `request` la funzione del token `I18NEXT_HTTP_BACKEND_CLIENT` e imposta `reloadInterval: false` per non lasciare un `setInterval` che impedirebbe all'SSR di terminare (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L55-L71). In SSR un `loadPath` relativo diventa assoluto premettendo `windowRef.location.origin` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L79-L91).
- `I18NEXT_HTTP_BACKEND_CLIENT` restituisce una funzione `(options, url, payload, callback)` che usa l'`HttpClient` di Angular con `responseType: 'text'`; in caso di errore passa `data: null` e lo status (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend-client.ts:L16-L44). Il commento della factory lo motiva così: "It uses Angular HttpClient under the hood, so it works in SSR" (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend-client.ts:L23-L26). Per come `HttpClient` passa la richiesta alla catena di interceptor vedi 06 — HttpClient e interceptor.
- `I18nextResourcesToBackendInitializer.hasMatch()` è true se c'è `i18n.backend.loader` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-resources-to-backend.initializer.ts:L23-L25); `initialize()` registra `I18nextResourcesToBackend(loader)` e restituisce `{ backend: {} }` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-resources-to-backend.initializer.ts:L27-L37). `DA VERIFICARE`: il modo in cui il plugin `i18next-resources-to-backend` chiama `loader(lng, ns)` non è verificabile, il pacchetto non è in `/tmp/deps`.

Le dipendenze dichiarate da `@spartacus/core` sono `i18next ^25.7.4`, `i18next-http-backend ^3.0.6` e `i18next-resources-to-backend ^1.2.2` (core-libs/core/package.json:L26-L28).

3.7 Tradurre una chiave: `I18nextTranslationService.translate`

1. Per ogni chiave (stringa o array) calcola il chunk e la chiave con namespace `chunk:key`, e le salva in un array e in una `Map` chiave → chunk (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L42-L53, core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L121-L123). Il separatore `:` coincide con il default `nsSeparator` di i18next (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1631-L1632).
2. Restituisce un Observable "freddo": a ogni subscribe, se `i18next.isInitialized` è false non fa nulla (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L55-L59).
3. Chiama `loadNamespaces(chunks, cb)`; nel callback, se `exists(namespacedKeys)` emette `t(namespacedKeys, options)`, altrimenti segnala la chiave mancante ed emette il valore di fallback (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L61-L79). Passare un array di chiavi a `t` attiva la catena di fallback di i18next: vince la prima chiave risolvibile, come dice il JSDoc di `TranslationService` (core-libs/core/src/i18n/translation.service.ts:L11-L21).
4. Se, al ritorno da `loadNamespaces`, il callback non è ancora stato chiamato e `whitespaceUntilLoaded` è true, emette subito uno spazio non separabile (carattere 160) (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L81-L84).
5. Si registra su `languageChanged` per ritradurre e si deregistra all'unsubscribe; l'Observable non completa mai (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L87-L89).

Il punto 3 regge sulla sincronia del callback: i commenti in testa al metodo chiedono di emettere **in modo sincrono** quando il chunk è già caricato, perché un'emissione differita innescherebbe change detection aggiuntive che, insieme a `switchMap`, possono creare loop infiniti (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L35-L40). In i18next, `loadNamespaces` aggiunge i namespace mancanti a `options.ns` e chiama `loadResources` (deps:i18next-25.7.4/package/dist/esm/i18next.js:L2075-L2089). Il callback è sincrono in due casi: senza backend registrato (il connettore emette un warn e chiama subito il callback, deps:i18next-25.7.4/package/dist/esm/i18next.js:L1548-L1552) e quando non c'è nulla da caricare né in sospeso (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1555-L1559). È questa la "cache under the hood" citata nel commento.

Il valore di fallback è `[chunk:key, ...]` in dev mode e uno spazio non separabile in produzione (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L100-L106); il warn sulle chiavi mancanti compare solo in dev mode ed elenca i chunk che si è tentato di caricare (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L108-L119).

`loadChunks(chunkNames)` delega direttamente a `i18next.loadNamespaces(chunkNames)` (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L93-L95).

3.8 La pipe `cxTranslate`

`TranslatePipe` si chiama `cxTranslate` ed è `pure: false` (core-libs/core/src/i18n/translate.pipe.ts:L25-L29): Angular la chiama a ogni change detection, e la pipe deve quindi decidere da sola quando risottoscriversi.

- Input falsy → `''`, con un `error` in dev mode (core-libs/core/src/i18n/translate.pipe.ts:L46-L53).
- Un `Translatable` con `raw` restituisce il testo così com'è; con `params` i parametri si uniscono alle options, e a parità di nome prevalgono i `params`; la chiave è `input.key` oppure l'input stesso (core-libs/core/src/i18n/translate.pipe.ts:L55-L63). `Translatable` ha `key?: string | string[]`, `params?`, `raw?`, e `isTranslatable` controlla che sia un oggetto non null con `key` o `raw` (core-libs/core/src/i18n/translatable.ts:L7-L23).
- La pipe si risottoscrive solo se cambia la chiave (confronto per riferimento) o se le options non sono shallow-equal; chiama `service.translate(key, options, true)`, quindi sempre con `whitespaceUntilLoaded`, e a ogni valore salva il risultato e chiama `cd.markForCheck()` (core-libs/core/src/i18n/translate.pipe.ts:L69-L89).
- `ngOnDestroy` chiude la subscription (core-libs/core/src/i18n/translate.pipe.ts:L91-L95).

Siccome la subscribe avviene dentro `transform` e il valore sincrono viene salvato prima del `return this.translatedValue` (core-libs/core/src/i18n/translate.pipe.ts:L65-L66), con un chunk già caricato il testo è disponibile già al primo passaggio di change detection.

3.9 Precaricamento dei chunk per i componenti CMS

Un mapping di componente CMS può dichiarare `i18nKeys?: string[]` (core-libs/core/src/cms/config/cms-config.ts:L76-L76). Quando le guard CMS di una pagina restituiscono `true`, `CmsPageGuardService` chiama `cmsI18n.loadForComponents(componentTypes)` (core-libs/storefront/cms-structure/guards/cms-page-guard.service.ts:L81-L85). `CmsComponentsService.getI18nKeys` raccoglie le chiavi dei soli componenti che devono essere renderizzati (core-libs/storefront/cms-structure/services/cms-components.service.ts:L266-L276), e `CmsI18nService` le converte in un `Set` di chunk e chiama `translation.loadChunks` (core-libs/storefront/cms-structure/services/cms-i18n.service.ts:L21-L28). Così i chunk lazy partono durante la navigazione, prima che i componenti vengano creati. A questo SHA, però, nessun mapping di componente del repo imposta `i18nKeys`: il meccanismo esiste ma è usato solo dalle app che lo configurano (grep su `*.ts`).

3.10 `cxDate` e `cxNumeric`

`CxDatePipe` (`cxDate`) estende `DatePipe` e chiama `super('')`, cioè con un `LOCALE_ID` vuoto (core-libs/core/src/i18n/date.pipe.ts:L12-L19). `transform` passa a `super.transform` come quarto argomento la lingua attiva (core-libs/core/src/i18n/date.pipe.ts:L25-L27); nel `DatePipe` di Angular prevale il locale passato, `locale || this.locale` (angular:packages/common/src/pipes/date_pipe.ts:L263-L275).

`getLang()` legge la lingua attiva in modo sincrono (subscribe seguita subito da unsubscribe, `''` se lo store non ha ancora emesso) e la valida con `getLocaleId(lang)`. Se Angular non ha i locale data per quella lingua, `getLocaleId` lancia, la pipe emette un warn (solo in dev mode) e ripiega su `'en'` (core-libs/core/src/i18n/date.pipe.ts:L29-L55). In Angular `findLocaleData` normalizza il codice (minuscolo, _ → -), prova il locale padre, ricade su `localeEn` se il padre è `en` e altrimenti lancia `MISSING_LOCALE_DATA` (angular:packages/core/src/i18n/locale_data_api.ts:L49-L72, angular:packages/core/src/i18n/locale_data_api.ts:L181-L183).

`CxNumericPipe` (`cxNumeric`) fa la stessa cosa sopra `DecimalPipe` (core-libs/core/src/i18n/numeric.pipe.ts:L12-L53), che in Angular usa `locale ||= this._locale` (angular:packages/common/src/pipes/number_pipe.ts:L109-L120). Una differenza: in `CxNumericPipe` i metodi di supporto sono `protected` (quindi estendibili), in `CxDatePipe` sono `private`.

Nessuna delle due dichiara `pure`, quindi sono pipe pure: il default di `@Pipe` è `{pure: true, ...p}` (angular:packages/core/src/metadata/directives.ts:L752-L752).

L'app demo registra i locale `de`, `ja`, `zh` con `registerLocaleData` (projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L29-L31); `en` è già incluso in Angular.

Date picker. Nelle librerie a questo SHA non esiste alcun componente DateTimePicker. Il selettore `cx-date-time-picker` sopravvive solo in un helper E2E Cypress (`fillDateTimePicker`), un residuo che non trova corrispondenza nel codice delle librerie (projects/storefrontapp-e2e-cypress/cypress/helpers/b2b/my-company/features/utils/form.ts:L85-L90). Il componente data dello storefront è `DatePickerComponent` (`cx-date-picker`), che importa `TranslatePipe` e `CxDatePipe` (core-libs/storefront/shared/components/form/date-picker/date-picker.component.ts:L27-L58). Il suo template usa un `<input type="date">` con placeholder e pattern presi da `DatePickerService`, e passa a `cx-form-errors` i limiti `min`/`max` formattati con `cxDate` e la label tradotta con `cxTranslate` (core-libs/storefront/shared/components/form/date-picker/date-picker.component.html:L1-L25). Il placeholder è fisso, `yyyy-mm-dd`, e non dipende dalla lingua attiva (core-libs/storefront/shared/components/form/date-picker/date-picker.service.ts:L24-L37). Il componente è trattato in 45 — Componenti storefront.

3.11 Da dove arrivano le traduzioni: `@spartacus/assets` e le feature lib

`@spartacus/assets` esporta `translationChunksConfig` e le traduzioni (core-libs/assets/src/public_api.ts:L11-L12). `translationChunksConfig` definisce 12 chunk core: `common` (18 namespace), `deliveryMode`, `myAccountV2Consent`, `myAccountV2NotificationPreference`, `myAccount`, `payment`, `pdf`, `product`, `pwa`, `siteThemeSwitcher`, `user`, `video` (core-libs/assets/src/translations/translations.ts:L7-L66). Lo stesso file riesporta 17 lingue con alias `translationsXx`: cs, de, en, es, es_CO, fr, hi, hu, id, it, ja, ko, pl, pt, ru, zh, zh_TW (core-libs/assets/src/translations/translations.ts:L68-L84). Ogni `index.ts` di lingua importa 12 JSON, uno per chunk, e li espone come oggetto `{ chunk: json }` (core-libs/assets/src/translations/en/index.ts:L7-L32).

L'app demo carica in modo eager en, ja, de e zh, passa `chunks: translationChunksConfig` e fissa `fallbackLang: 'en'` (projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L55-L67). Ogni modulo feature dell'app aggiunge le proprie risorse e i propri chunk con un altro `provideConfig(<I18nConfig>{ i18n: ... })`, che si fonde con deep merge (projects/storefrontapp/src/app/spartacus/features/order/order-feature.module.ts:L38-L48). Le traduzioni della feature sono fornite

eager, nel modulo root della feature, anche se il codice della feature è lazy (`featureModules` + `import()`, projects/storefrontapp/src/app/spartacus/features/order/order-feature.module.ts:L26-L33).

Ogni feature lib ha un secondary entry point `assets` (feature-libs/order/assets/public_api.ts:L7-L7) con una chunk config tipizzata `TranslationChunksConfig` di `@spartacus/core` e le 17 lingue riesportate con prefisso, es. `orderTranslationsEn` (feature-libs/order/assets/translations/translations.ts:L7-L42). Tra `feature-libs/` e `integration-libs/` ci sono 44 file `assets/translations/translations.ts`.

3.12 Generazione e validazione

- Lo script `build` di assets esegue `nx build assets` e poi `generate:translations:ts-2-json`; ci sono anche `properties-2-ts` (seguito da prettier) e `ts-2-properties` (core-libs/assets/package.json:L6-L11).
- `generate-translations-ts-2-json.ts` svuota e riscrive `dist/assets/i18n-assets/<lang>/<chunk>.json`, ma solo per `en`; se `dist/assets/` non esiste stampa un messaggio ed esce (core-libs/assets/generate-translations-ts-2-json.ts:L10-L43). Sono i file pensati per `loadPath: 'assets/i18n-assets/{{lng}}/{{ns}}.json'`, l'esempio del JSDoc (core-libs/core/src/i18n/config/i18n-config.ts:L37-L40). DA VERIFICARE: come un'app copi `dist/assets/i18n-assets` tra i propri asset; non è stata letta nessuna config `assets` di build che lo faccia.
- `build:libs` del repo esegue prima `scripts/i18n/validate-translations-json-files.ts` (package.json:L35-L35). Il validatore impone un limite di 50 KB per file e rifiuta valori, e chiavi delle sole foglie (stringhe), che contengono `<script`, `onerror`, `onload`, `onclick`, `javascript:`, `__proto__`, `constructor`, `eval` (scripts/i18n/validate-translations-json-files.ts:L9-L19). Le chiavi che puntano a oggetti annidati vengono attraversate senza controllo (scripts/i18n/validate-translations-json-files.ts:L39-L64). Ogni foglia deve essere una stringa e non deve avere la forma di un JSON (oggetto o array) (scripts/i18n/validate-translations-json-files.ts:L20-L73). Scansiona solo `feature-libs`, `integration-libs` e `projects` (scripts/i18n/validate-translations-json-files.ts:L97-L105).

---

4. Diagrammi

4.1 Bootstrap: dalla config all'istanza i18next pronta

■ **TAVOLA 37.1** diagramma a tutta pagina, in fondo al capitolo

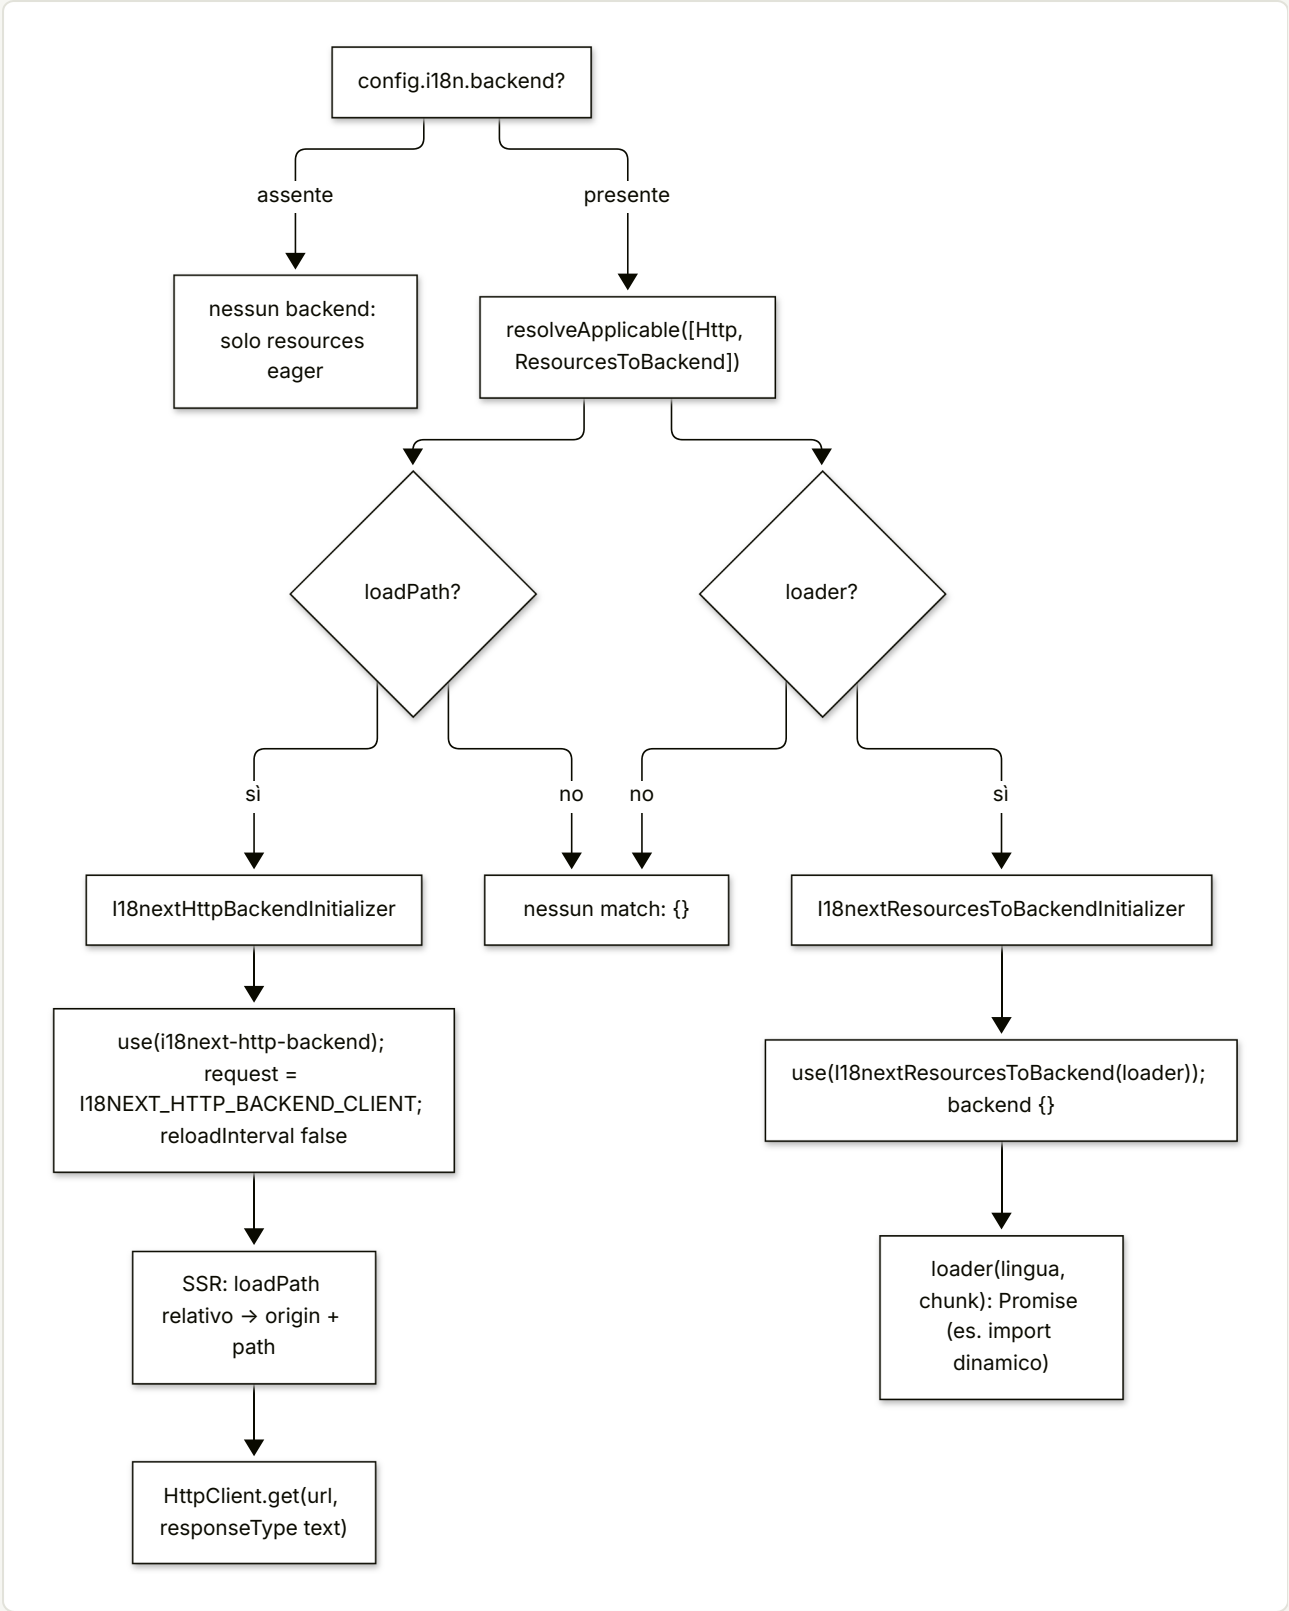
Riferimenti: core-libs/core/src/i18n/i18n.module.ts:L23-L56, core-libs/core/src/i18n/config/i18n-config-initializer.ts:L24-L33, core-libs/core/src/config/config-initializer/config-initializer.service.ts:L140-L166, core-libs/core/src/i18n/i18next/i18next-providers.ts:L14-L25, core-libs/core/src/i18n/i18next/i18next-initializer.ts:L36-L106, deps:i18next-25.7.4/package/dist/esm/i18next.js:L1834-L1850, deps:i18next-25.7.4/package/dist/esm/i18next.js:L1955-L1962.

4.2 `{{ 'key' | cxTranslate }}`: dal template al testo

■ **TAVOLA 37.2** diagramma a tutta pagina, in fondo al capitolo

Riferimenti: core-libs/core/src/i18n/translate.pipe.ts:L42-L89, core-libs/core/src/i18n/translation-chunk.service.ts:L39-L49, core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L42-L119.

4.3 Scelta del backend e lazy loading di un chunk



Se `loadPath` e `loader` sono entrambi presenti, entrambi corrispondono con pari priorità e vince il provider registrato per ultimo, cioè resources-to-backend (§9). Riferimenti: `core-libs/core/src/i18n/i18next/i18next-backend/i18next-backend.providers.ts:L12-L23`, `core-libs/core/src/util/applicable.ts:L63-L86`, `core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L38-L91`, `core-libs/`

core/src/i18n/i18next/i18next-backend/i18next-http-backend-client.ts:L27-L42, core-libs/core/src/i18n/i18next/i18next-backend/i18next-resources-to-backend.initializer.ts:L23-L37. Il passaggio finale del ramo `loader` dipende dal plugin esterno (DA VERIFICARE, §3.6).

---

5. Estratti di codice reale

Il fallback dinamico viene attivato solo se `fallbackLang` non è configurato — core-libs/core/src/i18n/i18n.module.ts:L23-L56

```ts
export function initI18nConfig(
  configInitializer: I18nConfigInitializer,
  config: I18nConfig
): ConfigInitializer | null {
  /**
   * If `fallbackLang` was already configured statically
   */
  if (config?.i18n?.fallbackLang !== undefined) {
    return null;
  }
  return configInitializer;
}

@NgModule({
  imports: [TranslatePipe, CxDatePipe, CxNumericPipe],
  exports: [TranslatePipe, CxDatePipe, CxNumericPipe],
})
export class I18nModule {
  static forRoot(): ModuleWithProviders<I18nModule> {
    return {
      ngModule: I18nModule,
      providers: [
        provideDefaultConfig(defaultI18nConfig),
        { provide: TranslationService, useExisting: I18nextTranslationService },
        ...i18nextProviders,
        {
          provide: CONFIG_INITIALIZER,
          useFactory: initI18nConfig,
          deps: [I18nConfigInitializer, I18nConfig],
          multi: true,
        },
      ],
    };
  }
}
```

L'`APP_INITIALIZER` aspetta lo scope `i18n` — core-libs/core/src/i18n/i18next/i18next-providers.ts:L13-L28

```ts
export const i18nextProviders: Provider[] = [
  {
    provide: APP_INITIALIZER,
    useFactory: () => {
      const configInitializerService = inject(ConfigInitializerService);
      const i18nextInitializer = inject(I18nextInitializer);
      return () =>
        lastValueFrom(configInitializerService.getStable('i18n')).then(() =>
          i18nextInitializer.initialize()
        );
    },
    multi: true,
  },

  ...i18nextBackendProviders,
];
```

Init di i18next: risorse statiche aggiunte nel callback — core-libs/core/src/i18n/i18next/i18next-initializer.ts:L36-L71

```ts
  initialize(): Promise<any> {
    const i18nextConfig = this.getI18nextConfig();
    return this.i18next.use(this.loggerPlugin).init(i18nextConfig, () => {
      // Don't use i18next's 'resources' config key for adding static translations,
      // because it will disable loading chunks from backend. We add resources here, in the init's
callback.
      this.addTranslationResources();
      this.synchronizeLanguage();
    });
  }

  /**
   * Returns the configuration for initializing an i18next instance.
   */
  protected getI18nextConfig(): InitOptions {
    let i18nextConfig: InitOptions = {
      ns: [], // don't preload any namespaces
      fallbackLng: this.config.i18n?.fallbackLang,
      debug: this.config.i18n?.debug,
      interpolation: {
        escapeValue: false,
        skipOnVariables: false,
      },

      // @ts-ignore -- In CXSPA-12377 we'll remove this @ts-ignore, after we upgrade to the latest
i18next version
      showSupportNotice: false,
    };
```

```
  if (this.config.i18n?.backend) {
    i18nextConfig = {
      ...i18nextConfig,
      ...this.i18nextBackendService.initialize(),
    };
  }

  return i18nextConfig;
}
```

Il cuore di `translate`: emissione sincrona, spazio non separabile in attesa, ritraduzione al cambio lingua — core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L55-L90

```ts
  return new Observable<string>((subscriber) => {
    const translate = () => {
      if (!this.i18next.isInitialized) {
        return;
      }

      // make sure chunks are loaded
      let namespacesLoaded = false;

      // loadNamespaces has cache under the hood, so it won't load the same chunk twice
      // when namespaces are already loaded, the callback will be called synchronously:
      this.i18next.loadNamespaces(
        Array.from(chunkNamesByKeys.values()),
        () => {
          namespacesLoaded = true;
          if (this.i18next.exists(namespacedKeys, options)) {
            subscriber.next(
              this.i18next.t(namespacedKeys, options) as string
            );
          } else {
            this.reportMissingKey(chunkNamesByKeys);
            subscriber.next(this.getFallbackValue(namespacedKeys));
          }
        }
      );

      // if namespaces are not loaded yet, we can emit a non-breaking space
      if (!namespacesLoaded && whitespaceUntilLoaded) {
        subscriber.next(this.NON_BREAKING_SPACE);
      }
    };

    translate();
```

```
    this.i18next.on('languageChanged', translate);
    return () => this.i18next.off('languageChanged', translate);
  });
```

Chiave → chunk, con ripiego sul namespace — core-libs/core/src/i18n/translation-chunk.service.ts:L39-L49

```ts
protected readonly KEY_SEPARATOR = '.';

getChunkNameForKey(key: string): string {
  const mainKey = (key || '').split(this.KEY_SEPARATOR)[0];
  const chunk = this.chunks && this.chunks[mainKey];

  if (!chunk) {
    return mainKey; // fallback to main key as a chunk
  }
  return chunk;
}
```

La pipe impura che si risottoscrive solo quando serve — core-libs/core/src/i18n/translate.pipe.ts:L69-L89

```ts
private translate(key: any, options: object) {
  if (
    key !== this.lastKey ||
    !ObjectComparisonUtils.shallowEqualObjects(options, this.lastOptions)
  ) {
    this.lastKey = key;
    this.lastOptions = options;

    if (this.sub) {
      this.sub.unsubscribe();
    }
    this.sub = this.service
      .translate(key, options, true)
      .subscribe((val) => this.markForCheck(val));
  }
}

private markForCheck(value: string) {
  this.translatedValue = value;
  this.cd.markForCheck();
}
```

HTTP backend: niente `setInterval` e URL assoluti in SSR — core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L55-L91

```ts
  protected getBackendConfig(): HttpBackendOptions {
    if (!this.config.i18n?.backend?.loadPath) {
      throw new Error('Missing config `i18n.backend.loadPath`.');
    }

    const loadPath = this.getLoadPath(this.config.i18n.backend.loadPath);

    const backend: HttpBackendOptions = {
      loadPath,
      request: this.i18nextHttpClient,

      // Disable the periodical reloading. Otherwise SSR would not finish due to the pending task `setInterval()`
      // ...
      reloadInterval: false,
    };
    return backend;
  }
  // ...
  protected getLoadPath(path: string): string {
    if (!this.windowRef.isBrowser() && !path.match(/^http(s)?:\/\//)) {
      if (path.startsWith('/')) {
        path = path.slice('/'.length);
      }
      if (path.startsWith('./')) {
        path = path.slice('./'.length);
      }
      const serverRequestOrigin = this.windowRef.location.origin;
      return `${serverRequestOrigin}/${path}`;
    }
    return path;
  }
```

Il client HTTP usato da i18next è l'`HttpClient` di Angular — core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend-client.ts:L27-L42

```ts
    return (
      _options: HttpBackendOptions,
      url: string,
      _payload: string | object,
      callback: RequestCallback
    ) => {
      httpClient.get(url, { responseType: 'text' }).subscribe({
        next: (data) => callback(null, { status: 200, data }),
        error: (error) =>
          callback(error, {
            // a workaround for https://github.com/i18next/i18next-http-backend/issues/82
            data: null as any,
```

```
          status: error.status,
        }),
    });
  };
```

`cxDate`: **lingua attiva come locale, ripiego su** `en` — `core-libs/core/src/i18n/date.pipe.ts:L25-L47`

```ts
transform(value: any, format?: string, timezone?: string): string | null {
  return super.transform(value, format, timezone, this.getLang());
}

private getLang() {
  const lang = this.getActiveLang();
  try {
    getLocaleId(lang);
    return lang;
  } catch {
    this.reportMissingLocaleData(lang);
    return 'en';
  }
}

private getActiveLang(): string {
  let result = '';
  this.language
    .getActive()
    .subscribe((lang) => (result = lang))
    .unsubscribe();
  return result;
}
```

Configurazione dell'app demo — `projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L55-L67`

```ts
  provideConfig({
    // we bring in static translations to be up and running soon right away
    i18n: {
      resources: {
        en: translationsEn,
        ja: translationsJa,
        de: translationsDe,
        zh: translationsZh,
      },
      chunks: translationChunksConfig,
      fallbackLang: 'en',
    },
  }),
```

6. Configurazione

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
i18n.fallbackLang	string | false	undefined (core-libs/core/src/i18n/config/default-i18n-config.ts:L9-L14); se resta undefined diventa context.language[0]	core-libs/core/src/i18n/config/i18n-config.ts:L20-L23	core-libs/core/src/i18n/i18n.module.ts:L30-L32, core-libs/core/src/i18n/config/i18n-config-initializer.ts:L24-L33, core-libs/core/src/i18n/i18next/i18next-initializer.ts:L52-L52
i18n.backend.loadPath	string con {{lng}} e {{ns}}	assente	core-libs/core/src/i18n/config/i18n-config.ts:L31-L51	core-libs/core/src/i18n/i18next/i18next-initializer.ts:L63-L63, core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L38-L40, core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L55-L60
i18n.backend.loader	(language, chunkName) => Promise<TranslationResourceKey>	assente	core-libs/core/src/i18n/config/i18n-config.ts:L53-L71	core-libs/core/src/i18n/i18next/i18next-backend/i18next-resources-to-backend.initializer.ts:L23-L34
i18n.resources	TranslationResources (lingua → chunk → oggetto)	assente (?? {})	core-libs/core/src/i18n/config/i18n-config.ts:L74-L78, tipo in core-libs/core/src/i18n/translation-resources.ts:L7-L18	core-libs/core/src/i18n/i18next/i18next-initializer.ts:L79-L92
i18n.debug	boolean	false (core-libs/core/src/i18n/config/default-i18n-config.ts:L12-L12)	core-libs/core/src/i18n/config/i18n-config.ts:L80-L83	core-libs/core/src/i18n/i18next/i18next-initializer.ts:L53-L53 (opzione debug di i18next, che sblocca log/warn del logger)
i18n.chunks	{ [chunk: string]: string[] }	assente (|| {})	core-libs/core/src/i18n/config/i18n-config.ts:L85-L90	core-libs/core/src/i18n/translation-chunk.service.ts:L21-L21
context.language (esterna, site context)	string[]	—	site context (13)	core-libs/core/src/i18n/config/i18n-config-initializer.ts:L25-L29
CmsComponentMapping.i18nKeys (esterna, CMS)	string[]	assente	core-libs/core/src/cms/config/cms-config.ts:L76-L76	core-libs/storefront/cms-structure/services/cms-components.service.ts:L266-L276

Opzioni i18next imposte da Spartacus e non configurabili via I18nConfig (si cambiano solo estendendo I18nextInitializer.getI18nextConfig): ns: [], interpolation.escapeValue: false, interpolation.skipOnVariables: false, showSupportNotice: false (core-libs/core/src/i18n/i18next/i18next-

initializer.ts:L50-L61); per il backend HTTP `reloadInterval: false` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L68-L68).

Esempio di config lazy, citato letteralmente dai JSDoc: `loadPath: 'assets/i18n-assets/{{lng}}/{{ns}}.json'` (core-libs/core/src/i18n/config/i18n-config.ts:L37-L40) e `loader: (language, chunkName) => import(`../../assets/i18n-assets/${language}/${chunkName}.json`)` (core-libs/core/src/i18n/config/i18n-config.ts:L63-L66). Il JSDoc di `loadPath` lo sconsiglia per gli asset locali e raccomanda `loader`, "more performant (especially in SSR)" (core-libs/core/src/i18n/config/i18n-config.ts:L42-L48).

---

7. Commenti e note notevoli dal sorgente

- *"Each SSR request gets its own instance of i18next. ... The reference to the static global instance of `i18next` ... should not be used anywhere else, because otherwise it would be shared in between all SSR requests and can cause concurrency issues."* — core-libs/core/src/i18n/i18next/i18next-instance.ts:L10-L18. È la regola d'oro per chi scrive estensioni: mai `import i18next from 'i18next'` per usare l'istanza globale, sempre `inject(I18NEXT_INSTANCE)`.
- *"Don't use i18next's 'resources' config key for adding static translations, because it will disable loading chunks from backend."* — core-libs/core/src/i18n/i18next/i18next-initializer.ts:L39-L40.
- *"@ts-ignore -- In CXSPA-12377 we'll remove this @ts-ignore, after we upgrade to the latest i18next version"* — core-libs/core/src/i18n/i18next/i18next-initializer.ts:L59-L60. In i18next 25.7.4 l'opzione `showSupportNotice` non esiste nel sorgente ESM, quindi oggi viene semplicemente ignorata. DA VERIFICARE: a quale versione di i18next si riferisca CXSPA-12377 non si può verificare qui.
- *"Moreover, we SHOULD emit a value (or a fallback value) synchronously (not in a promise/setTimeout). Otherwise, we the will trigger additional deferred change detection ... which together with `switchMap` operator may lead to an infinite loop."* — core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L38-L40.
- *"Required param added in 3.0.x as a critical bug fix, not subject to the breaking changes policy"* — core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L26-L27. È il parametro `I18NEXT_INSTANCE`. Con ogni probabilità il bug è la condivisione dell'istanza globale tra richieste SSR descritta nel JSDoc del token (core-libs/core/src/i18n/i18next/i18next-instance.ts:L10-L18); è un'inferenza, il commento non lo dice.
- *"Disable the periodical reloading. Otherwise SSR would not finish due to the pending task `setInterval()`"* — core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L66-L68.
- *"It's needed, because Angular Universal doesn't support relative URLs in HttpClient."* — core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L73-L78, con i link alle issue angular#19224 e universal#858.
- *"a workaround for https://github.com/i18next/i18next-http-backend/issues/82"* — core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend-client.ts:L37-L37.
- *"By default it configures and uses the `I18nextHttpBackendService`."* — core-libs/core/src/i18n/i18next/i18next-backend/i18next-backend.service.ts:L15-L15. Il nome è sbagliato: la classe reale si chiama `I18nextHttpBackendInitializer`.
- *"type CxDatePipe, not DatePipe, due to conflict with Angular's DatePipe - problem occurs for the backward compatibility compiler of Ivy"* — core-libs/core/src/i18n/date.pipe.ts:L12-L12.
- *"TODO: Replace `any` to match strict types from angular in 4.0"* — core-libs/core/src/i18n/date.pipe.ts:L21-L22: un TODO rimasto da molte major.

- *"the first language in the array is the default one"* — core-libs/core/src/i18n/config/i18n-config-initializer.ts:L28-L28.
- *"fallback to main key as a chunk"* — core-libs/core/src/i18n/translation-chunk.service.ts:L46-L46.
- *"Only returns the date if we have a valid format. We do this to avoid loads of console errors coming from the datePipe while the user is typing"* — core-libs/storefront/shared/components/form/date-picker/date-picker.component.ts:L60-L68.

8. Extension point

EXTENSION POINT	COME SI USA	RIFERIMENTO	PUBBLICO?
`provideConfig({ i18n: { resources, chunks } })`	aggiungere o sovrascrivere traduzioni (deep merge, `addResourceBundle` con overwrite)	core-libs/core/src/i18n/i18next/i18next-initializer.ts:L79-L92	sì (`I18nConfig` in core-libs/core/src/i18n/index.ts:L7-L7)
`i18n.backend.loadPath` / `loader`	lazy loading via HTTP o `import()`	core-libs/core/src/i18n/config/i18n-config.ts:L30-L72	sì
`TranslationService`	sostituire l'intero motore (es. un altro framework i18n) con `{ provide: TranslationService, useClass: ... }`	core-libs/core/src/i18n/translation.service.ts:L9-L35; binding core-libs/core/src/i18n/i18n.module.ts:L46-L46	sì
`I18nextTranslationService`	estendere, es. `protected getFallbackValue` per cambiare il testo delle chiavi mancanti	core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L100-L106	sì
`TranslationChunkService`	cambiare la regola chiave → chunk (`getChunkNameForKey`)	core-libs/core/src/i18n/translation-chunk.service.ts:L41-L49	sì
`I18nextInitializer`	cambiare le opzioni di i18next (`protected getI18nextConfig`) o la sincronizzazione della lingua	core-libs/core/src/i18n/i18next/i18next-initializer.ts:L49-L106	sì
`I18nConfigInitializer`	cambiare la regola del fallback dinamico (`protected resolveConfig`)	core-libs/core/src/i18n/config/i18n-config-initializer.ts:L24-L33	sì
`I18nextBackendInitializer` (multi)	aggiungere un altro plugin backend di i18next con `hasMatch` (dichiarato nella classe) e `getPriority` (opzionale, ereditato dall'interfaccia `Applicable`)	core-libs/core/src/i18n/i18next/i18next-backend/i18next-backend.initializer.ts:L15-L26, core-libs/core/src/util/applicable.ts:L44-L44; selezione core-libs/core/src/util/applicable.ts:L63-L86	sì
`I18NEXT_HTTP_BACKEND_CLIENT`	sostituire la funzione `request` (header, cache, retry)	core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend-client.ts:L16-L44	sì

EXTENSION POINT	COME SI USA	RIFERIMENTO	PUBBLICO?
`I18nextHttpBackendInitializer`	estendere `protected getBackendConfig`/`getLoadPath` (es. altre opzioni del plugin)	`core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L55-L91`	sì
`I18NEXT_INSTANCE`	accedere all'istanza per richiesta (mai all'import globale)	`core-libs/core/src/i18n/i18next/i18next-instance.ts:L19-L22`	sì
`CmsComponentMapping.i18nKeys`	precaricare i chunk dei componenti CMS di una pagina	`core-libs/core/src/cms/config/cms-config.ts:L76-L76`	sì (cms)
`CxNumericPipe`	estendere (metodi `protected`)	`core-libs/core/src/i18n/numeric.pipe.ts:L26-L52`	sì
`I18nTestingModule` e mock	test di componenti con chiavi "parlanti"	`core-libs/core/src/i18n/testing/i18n-testing.module.ts:L13-L20`	sì

Non pubblici, quindi da non usare: `I18NEXT_LOGGER_PLUGIN` e `i18nextProviders` (non esportati da `core-libs/core/src/i18n/i18next/index.ts:L7-L10`), `initI18nConfig` (di `i18n.module` si esporta solo `I18nModule`, `core-libs/core/src/i18n/index.ts:L7-L18`), `defaultI18nConfig`, `mockTranslate` (`core-libs/core/src/i18n/testing/index.ts:L7-L10`).

Esempio: un backend personalizzato. Lo schema che segue usa solo i simboli pubblici visti sopra. È uno schema illustrativo, non codice del repo:

```ts
// Schema illustrativo (non presente nel repo)
@Injectable({ providedIn: 'root' })
export class MyBackendInitializer implements I18nextBackendInitializer {
  protected i18next = inject(I18NEXT_INSTANCE);
  protected config = inject(I18nConfig);
  hasMatch() { return !!this.config.i18n?.backend; }
  getPriority() { return Priority.HIGH; } // batte i due backend di default
  initialize(): InitOptions {
    this.i18next.use(/* plugin backend i18next */);
    return { backend: { /* opzioni del plugin */ } };
  }
}
// provider: { provide: I18nextBackendInitializer, useExisting: MyBackendInitializer, multi: true }
```

Ricette in Parte III:

- traduzioni, override delle chiavi, chunk per una feature custom: 53 — Ricette: feature lib, carrello/checkout, stili, traduzioni;
- override di servizi via DI e config: 50 — Ricette: configurazione, DI, interceptor, eventi;
- cosa è API pubblica e cosa no: 54 — API pubblica vs interna, upgrade.

9. Trappole, casi limite, comportamenti controintuitivi

1. `loadPath` **e** `loader` **insieme: vince** `loader`**.** Entrambi i backend corrispondono e nessuno dei due ha `getPriority`. `resolveApplicable` fa vincere, a parità di priorità, il provider registrato per ultimo, che è `I18nextResourcesToBackendInitializer`; `loadPath` viene ignorato senza avvisi (core-libs/core/src/i18n/i18next/i18next-backend/i18next-backend.providers.ts:L12-L23, core-libs/core/src/util/applicable.ts:L72-L86).
2. `i18n.backend: {}` **senza** `loadPath` **né** `loader`**.** Nessun initializer corrisponde e `I18nextBackendService` restituisce `{}`: niente backend e niente errore (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L63-L68, core-libs/core/src/i18n/i18next/i18next-backend/i18next-backend.service.ts:L33-L38).
3. **Le traduzioni eager non disattivano il lazy loading.** Proprio perché vengono aggiunte nel callback di init e non come opzione `resources` di i18next, risorse eager e chunk lazy convivono (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L38-L43, deps:i18next-25.7.4/package/dist/esm/i18next.js:L1853-L1857).
4. `fallbackLang: false`**.** Impostato staticamente disattiva il fallback dinamico (il test è `!== undefined`) e arriva a i18next come `fallbackLng: false`, quindi nessuna lingua di ripiego (core-libs/core/src/i18n/i18n.module.ts:L30-L32, core-libs/core/src/i18n/i18next/i18next-initializer.ts:L52-L52).
5. **Namespace dimenticato in** `chunks`**.** Il chunk diventa il namespace stesso. Con un backend HTTP si vedrà una richiesta a `.../<namespace>.json`, probabilmente in 404, invece del chunk previsto (core-libs/core/src/i18n/translation-chunk.service.ts:L41-L49). Al contrario, le risorse eager sono indicizzate per *chunk*: se in `resources` metti `{ en: { order: {...} } }` ma la chiave `orderDetails.x` è mappata al chunk `order`, la chiave risolta è `order:orderDetails.x`, che cerca `orderDetails.x` dentro il bundle `order`.
6. **Namespace duplicati tra chunk.** Vince il primo in ordine di `Object.keys`, e l'avviso compare solo in dev mode (core-libs/core/src/i18n/translation-chunk.service.ts:L22-L36).
7. **Chiavi mancanti silenziose in produzione.** In produzione la chiave mancante diventa uno spazio non separabile, senza log; solo in dev mode si vede `[chunk:key]` con un warn (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L100-L119).
8. **Prima dell'init non arriva nulla.** Se ci si sottoscrive a `translate()` prima che i18next sia inizializzato, l'Observable non emette e si "risveglia" solo al primo `languageChanged`; `TranslatePipe` restituisce `translatedValue` non ancora assegnato (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L57-L59, core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L87-L89, core-libs/core/src/i18n/translate.pipe.ts:L65-L66). Dato che la Promise dell'`APP_INITIALIZER` si risolve solo a init completato (§3.3), il caso riguarda soprattutto codice che si sottoscrive durante l'inizializzazione dell'app.
9. `translate()` **non completa mai.** Chi lo usa nel codice TypeScript deve gestire l'unsubscribe, oppure usare `take(1)` o `firstValueFrom` quando basta un valore. La pipe lo fa in `ngOnDestroy` (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L87-L89, core-libs/core/src/i18n/translate.pipe.ts:L91-L95). Attenzione: con `whitespaceUntilLoaded = true` e un chunk non ancora caricato, il primo valore è lo spazio non separabile (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L81-L84).
10. **Array letterali nella pipe.** `{{ ['a.b', 'c.d'] | cxTranslate }}`: la chiave array è confrontata per riferimento, quindi se il template produce un array nuovo a ogni ciclo la pipe si risottoscrive a ogni change detection (core-libs/core/src/i18n/translate.pipe.ts:L70-L72). DA VERIFICARE: se il compilatore Angular memoizzi gli array letterali costanti nei template (pure function) non è stato verificato qui; il rischio concreto riguarda gli array costruiti nel componente con un getter.
11. `escapeValue: false`**.** i18next non esegue l'escaping dei valori interpolati (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L54-L57). Con il binding di testo `{{ }}` l'escaping lo fa Angular; con

`[innerHTML]="'x' | cxTranslate: { name }"` un parametro controllato dall'utente finisce nell'HTML, sanificato solo dal sanitizer di Angular.

12. `cxDate` **e** `cxNumeric` **non reagiscono al cambio lingua.** Sono pipe pure: se cambi lingua e la data non cambia, il testo resta formattato nella lingua precedente finché l'input non cambia (core-libs/core/src/i18n/date.pipe.ts:L13-L13, core-libs/core/src/i18n/numeric.pipe.ts:L12-L12, angular:packages/core/src/metadata/directives.ts:L752-L752).
13. **Lingua non ancora nello store.** `getActiveLang()` restituisce `''`; in Angular `getLocaleData('')` non trova nulla, il padre `''` neanche, e poiché `'' !== 'en'` `findLocaleData` lancia. La pipe ripiega quindi su `'en'` e in dev mode emette un warn con locale `''` (core-libs/core/src/i18n/date.pipe.ts:L40-L47, angular:packages/core/src/i18n/locale_data_api.ts:L105-L123, angular:packages/core/src/i18n/locale_data_api.ts:L49-L72).
14. **Locale non registrati.** Senza `registerLocaleData` della lingua, `cxDate` e `cxNumeric` usano `'en'`. L'app demo registra solo de, ja, zh (core-libs/core/src/i18n/date.pipe.ts:L29-L38, projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L29-L31). I codici con underscore (`es_CO`, `zh_TW`) vengono normalizzati da Angular in `es-co` / `zh-tw`, e si prova anche il padre (angular:packages/core/src/i18n/locale_data_api.ts:L181-L183).
15. **Il placeholder del date picker non è localizzato.** È sempre `yyyy-mm-dd` (core-libs/storefront/shared/components/form/date-picker/date-picker.service.ts:L24-L37).
16. `I18nTestingModule` **non ha** `cxNumeric`**.** I test di componenti che usano `cxNumeric` devono dichiararlo a parte (core-libs/core/src/i18n/testing/i18n-testing.module.ts:L13-L20). Inoltre `MockTranslationService` completa dopo il primo valore, a differenza dell'implementazione reale (core-libs/core/src/i18n/testing/mock-translation.service.ts:L14-L28).
17. **Il warn "No backend was added...".** Senza backend, ogni `loadNamespaces` passa dal connettore, che registra `'No backend was added via i18next.use. Will not load resources.'`; si vede solo con `debug: true`, perché `warn` del logger i18next è riservato al debug (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1548-L1552, deps:i18next-25.7.4/package/dist/esm/i18next.js:L219-L231).
18. **HTTP backend in SSR e origine.** Un `loadPath` relativo viene reso assoluto con `windowRef.location.origin`: se l'origine vista dal server è sbagliata (proxy, host interno) le richieste vanno all'host sbagliato (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L79-L91). DA VERIFICARE: come venga popolato `location.origin` lato server è materia di 39 — SSR ottimizzato.
19. **Cambi di lingua rapidi.** `changeLanguage` notifica `languageChanged` solo per l'ultima lingua richiesta (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1955-L1962).
20. **Traduzioni delle feature lazy caricate eager.** Nell'app demo le risorse di una feature lazy sono fornite nel modulo root della feature, quindi finiscono nel bundle iniziale anche se il codice della feature è lazy (projects/storefrontapp/src/app/spartacus/features/order/order-feature.module.ts:L26-L48). Per evitarlo serve un backend lazy.
21. **Script di assets rotti.** `generate-translations-ts-2-properties.ts` e `generate-translations-properties-2-ts.ts` importano `{ translations }` da `./src/translations/translations` (core-libs/assets/generate-translations-ts-2-properties.ts:L8-L8, core-libs/assets/generate-translations-properties-2-ts.ts:L8-L8), ma quel file esporta solo `translationChunksConfig` e `translationsXx` (core-libs/assets/src/translations/translations.ts:L7-L84): così non compilano. `properties-2-ts`, inoltre, presuppone file di chunk `.ts` della forma `export const x = {...}` (core-libs/assets/generate-translations-properties-2-ts.ts:L56-L71), mentre le cartelle lingua contengono JSON importati da `index.ts` (core-libs/assets/src/translations/en/index.ts:L7-L18). Anche il README di assets cita `import { translations } from '@spartacus/assets';` (core-libs/assets/README.md:L1-L5), un export che non esiste. La cartella `lang/properties` contiene solo `dummy.txt`.
22. **Piccoli bug negli script.** In `ts-2-properties`, `_prefix + '=' + jsonObj[key] || ''` applica `|| ''` all'intera stringa concatenata, quindi il fallback non ha mai effetto (core-libs/assets/generate-translations-ts-

2-properties.ts:L28-L28). In `properties-2-ts`, `property.split('=')[1]` tronca i valori che contengono `=` (core-libs/assets/generate-translations-properties-2-ts.ts:L14-L15).

23. **JSON lazy solo per** `en`**.** `ts-2-json` produce gli asset solo per l'inglese (core-libs/assets/generate-translations-ts-2-json.ts:L32-L40): chi vuole il lazy loading HTTP per altre lingue deve generarli da sé.
24. **Il validatore non guarda** `core-libs`**.** Le traduzioni core in `core-libs/assets/src/translations/**` non vengono validate da `build:libs` (scripts/i18n/validate-translations-json-files.ts:L97-L105).
25. **Tipi duplicati.** `TranslationChunksConfig` è definita sia in core sia in assets (core-libs/core/src/i18n/translation-resources.ts:L16-L18, core-libs/assets/src/translations/translation-chunks-config.ts:L7-L9), e `translationChunksConfig` del core non è tipizzato, mentre quelli delle feature lib sì (core-libs/assets/src/translations/translations.ts:L7-L7, feature-libs/order/assets/translations/translations.ts:L7-L9).

---

10. Come fare debug

- **Vedere cosa fa i18next.** Imposta `provideConfig({ i18n: { debug: true } })`: l'opzione arriva a i18next (core-libs/core/src/i18n/i18next/i18next-initializer.ts:L53-L53) e sblocca `log`/`warn` del logger, che passano dal plugin a `LoggerService` (core-libs/core/src/i18n/i18next/i18next-plugins/i18next-logger-plugin.ts:L17-L40). Vedrai `initialized`, `languageChanged` (deps:i18next-25.7.4/package/dist/esm/i18next.js:L1834-L1840, deps:i18next-25.7.4/package/dist/esm/i18next.js:L1955-L1963) e i warn del connettore. Il JSDoc avverte: "Don't use in production!" (core-libs/core/src/i18n/config/i18n-config.ts:L80-L83).
- **Chiavi mancanti.** In dev mode compaiono come `[chunk:key]` nella UI, con un warn `Translation keys missing [...] Attempted to load 'key' from chunk 'chunk'` (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L108-L119). Se il chunk indicato non è quello atteso, controlla `i18n.chunks` e cerca nei log l'avviso sui duplicati (core-libs/core/src/i18n/translation-chunk.service.ts:L51-L65).
- **Ispezionare l'istanza.** Da un componente o servizio di debug, `inject(I18NEXT_INSTANCE)` restituisce l'istanza per root injector (core-libs/core/src/i18n/i18next/i18next-instance.ts:L19-L22); proprietà come `isInitialized` sono quelle che il servizio di traduzione controlla (core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L57-L57).
- **Testo vuoto o "spazio" persistente.** Se resta uno spazio non separabile: in produzione può essere una chiave mancante (§9.7); in qualunque modalità può essere un chunk che non arriva (backend che fallisce: con l'HTTP backend l'errore passa da `HttpClient`, core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend-client.ts:L33-L41, ed è quindi visibile nel tab Network).
- **Backend HTTP in SSR.** Controlla che l'URL calcolato sia assoluto e con l'origine giusta (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L79-L91); se il rendering SSR non termina, verifica di non aver sovrascritto `reloadInterval` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L66-L68).
- **Date in inglese inattese.** Cerca in dev mode il warn `cxDate pipe: No locale data registered for '<lang>'` (core-libs/core/src/i18n/date.pipe.ts:L49-L55) e aggiungi `registerLocaleData` per quella lingua.
- **Backend sbagliato.** Se hai sia `loadPath` sia `loader`, ricorda §9.1. Per capire quale vince, metti un breakpoint in `I18nextBackendService.initialize` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-backend.service.ts:L33-L38).
- **Nei test** usa `I18nTestingModule`: le chiavi diventano stringhe leggibili come `key name:value` (core-libs/core/src/i18n/testing/mock-translate.ts:L7-L18), comode da cercare nel DOM. Vedi 44 — Test e

tooling.

---

11. Domande di autoverifica

1. **Perché `I18NEXT_INSTANCE` usa `createInstance()` invece dell'import di default di i18next?** Perché in SSR ogni richiesta ha il proprio root injector e quindi la propria istanza; l'istanza globale sarebbe condivisa tra richieste concorrenti. — core-libs/core/src/i18n/i18next/i18next-instance.ts:L10-L22
2. **Se non configuro `i18n.fallbackLang`, quale lingua di fallback userà i18next?** La prima lingua di `context.language`, calcolata da `I18nConfigInitializer` dopo che lo scope `context.language` è stabile. — core-libs/core/src/i18n/i18n.module.ts:L23-L34, core-libs/core/src/i18n/config/i18n-config-initializer.ts:L24-L33
3. **Perché Spartacus non passa le traduzioni statiche nell'opzione `resources` di `init`?** Perché con `resources` i18next non userebbe più il backend per i chunk lazy; Spartacus le aggiunge con `addResourceBundle` nel callback di init. — core-libs/core/src/i18n/i18next/i18next-initializer.ts:L38-L43, deps:i18next-25.7.4/package/dist/esm/i18next.js:L1853-L1857
4. **Come viene risolta la chiave `searchBox.placeholder` con la config di `@spartacus/assets`?** Il namespace è `searchBox`, mappato al chunk `common`; la chiave passata a i18next è `common:searchBox.placeholder`. — core-libs/core/src/i18n/translation-chunk.service.ts:L41-L49, core-libs/assets/src/translations/translations.ts:L7-L27, core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L121-L123
5. **Perché `translate()` deve emettere in modo sincrono quando il chunk è già caricato, e come ci riesce?** Un'emissione differita innescherebbe change detection aggiuntive che, con `switchMap`, possono causare loop infiniti. Ci riesce perché `loadNamespaces` chiama il callback in modo sincrono quando non c'è nulla da caricare. — core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L35-L40, deps:i18next-25.7.4/package/dist/esm/i18next.js:L1555-L1559
6. **Cosa mostra `cxTranslate` per una chiave mancante, in dev e in produzione?** In dev `[chunk:key]` più un warn; in produzione uno spazio non separabile, senza log. — core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L100-L119
7. **Configuro sia `backend.loadPath` sia `backend.loader`: quale backend viene usato?** `I18nextResourcesToBackendInitializer` (il `loader`): entrambi corrispondono con pari priorità e vince il provider registrato per ultimo. — core-libs/core/src/i18n/i18next/i18next-backend/i18next-backend.providers.ts:L12-L23, core-libs/core/src/util/applicable.ts:L72-L86
8. **Perché il backend HTTP imposta `reloadInterval: false`?** Per non lasciare un `setInterval` pendente, che impedirebbe all'SSR di terminare. — core-libs/core/src/i18n/i18next/i18next-backend/i18next-http-backend.initializer.ts:L66-L68
9. **Cambio lingua da `en` a `de`: perché i testi cambiano ma le date formattate con `cxDate` possono restare in inglese?** `cxTranslate` è impura e il servizio ritraduce a ogni `languageChanged`; `cxDate` è pura e si ricalcola solo se cambia l'input. Inoltre senza `registerLocaleData` per `de` ripiega comunque su `en`. — core-libs/core/src/i18n/translate.pipe.ts:L25-L29, core-libs/core/src/i18n/i18next/i18next-translation.service.ts:L87-L89, angular:packages/core/src/metadata/directives.ts:L752-L752, core-libs/core/src/i18n/date.pipe.ts:L29-L38
10. **Come si fa a far partire il download dei chunk di una pagina CMS prima che i componenti vengano creati?** Dichiarando `i18nKeys` nel mapping del componente CMS: quando le guard della pagina passano, `CmsPageGuardService` chiama `CmsI18nService.loadForComponents`, che chiama `TranslationService.loadChunks`. — core-libs/core/src/cms/config/cms-config.ts:L76-L76, core-libs/storefront/cms-

structure/guards/cms-page-guard.service.ts:L81-L85, core-libs/storefront/cms-structure/services/cms-i18n.service.ts:L21-L28

TAVOLA 37.1 **4.1 Bootstrap: dalla config all'istanza i18next pronta**

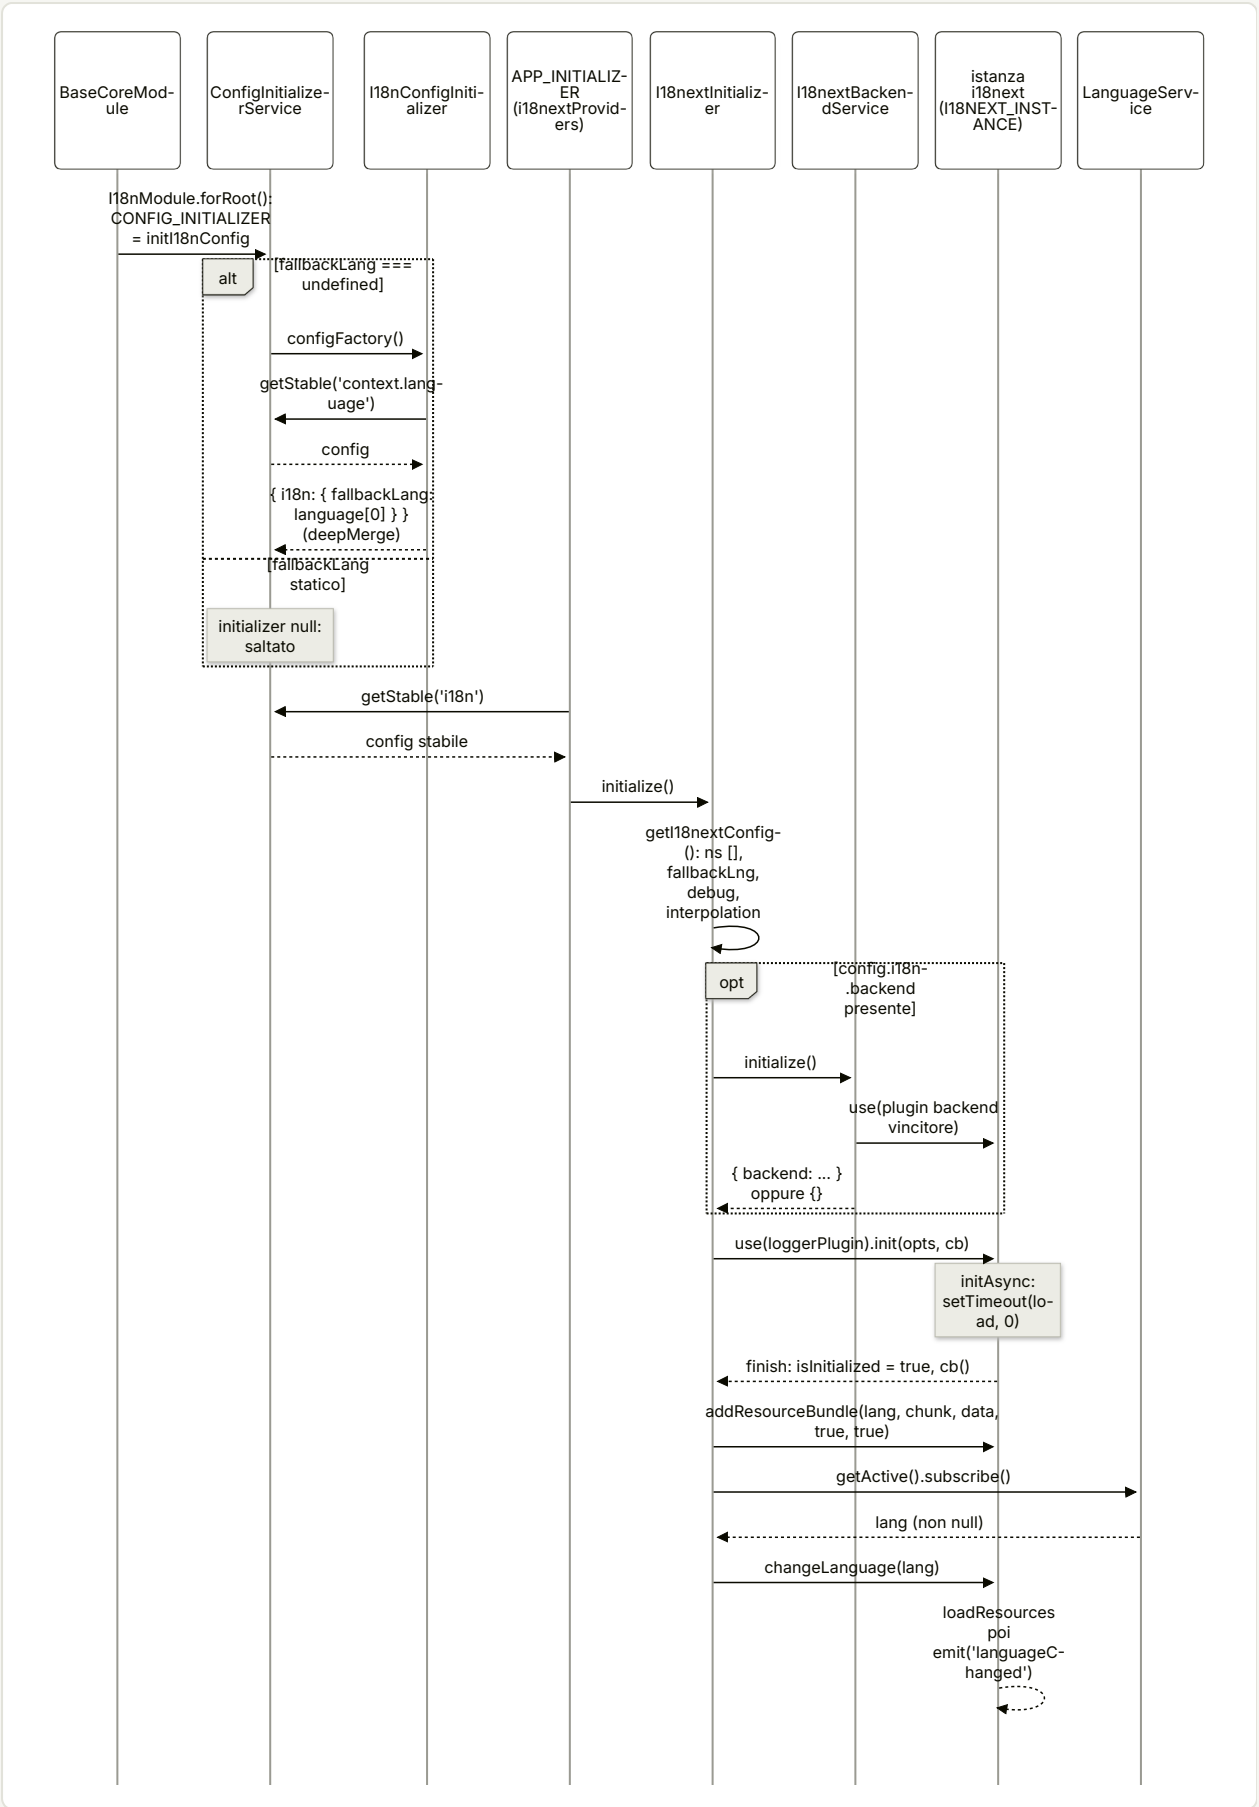


TAVOLA 37.2 **4.2 {{ 'key' | cxTranslate }}: dal template al testo**

1. A cosa serve e perché esiste

Spartacus separa nettamente la logica (librerie Angular in `@spartacus/core`, `@spartacus/storefront` e nelle feature lib) dall'aspetto grafico, che vive quasi per intero in un pacchetto a sé: `@spartacus/styles`, sorgente in `core-libs/styles/`. Il pacchetto non contiene TypeScript né CSS precompilato: è una libreria **Sass** distribuita come sorgente. Il `package.json` dichiara come entry Sass `./_index.scss` (campo `"sass"`) — `core-libs/styles/package.json:L2-L3`, `core-libs/styles/package.json:L31-L31` — il progetto Nx `storefrontstyles` ha solo un target di test e nessun target di build — `core-libs/styles/project.json:L2-L14` — e in fase di release i file vengono copiati tali e quali (`cp -r core-libs/styles/* ../.`) — `ci-scripts/release-packer.sh:L42-L43`. La compilazione avviene quindi **nell'applicazione consumer**, dentro la pipeline di build Angular, che vede tutte le variabili Sass e può modificarle prima che il CSS venga emesso.

Questa scelta abilita il modello di personalizzazione di Spartacus, che lavora su tre livelli:

1. **Compile time (Sass)**: variabili `!default` del tema (colori, tipografia, flag di componente come `$useTabsOnPDP`), liste di selettori da emettere (`$<area>-components-allowlist`, `$skipComponentStyles`, `$page-template-allowlist`) e placeholder `%cx-*` ridefinibili — `core-libs/styles/scss/theme/santorini/_variables.scss:L1-L9`, `core-libs/styles/scss/_components.scss:L1-L53`.
2. **Runtime (CSS custom property)**: `root.scss` traduce la mappa Sass `$theme-colors` in proprietà `--cx-color-*` su `:root`, che i componenti leggono con `var(...)`; basta ridefinirle su una classe per ottenere un tema diverso senza ricompilare — `core-libs/styles/scss/root.scss:L1-L6`.
3. **Runtime (classi sul DOM gestite da TypeScript)**: `ThemeService` mette sul root component la classe del *site theme* attivo (per esempio `cx-theme-high-contrast-dark`) — `core-libs/storefront/layout/theme/theme.service.ts:L52-L61` —, `FeatureStylesService` aggiunge classi `cxFeat_<flag>` per gli stili condizionati da feature toggle — `core-libs/core/src/features-config/services/feature-styles.service.ts:L89-L95` — e `DirectionService` imposta l'attributo `dir` su `<html>` in base alla lingua — `core-libs/storefront/layout/direction/direction.service.ts:L89-L95`.

Sotto tutto c'è una copia **vendorizzata di Bootstrap 4.6.2** (`core-libs/styles/vendor/bootstrap/`) — `core-libs/styles/vendor/bootstrap/scss/bootstrap.scss:L1-L7` — di cui Spartacus riusa funzioni, mixin, variabili e una selezione di parziali (reboot, grid, utilities, buttons, forms, modal…), personalizzandoli nei blocchi `cxbase`.

Il capitolo copre: struttura e ordine di import del pacchetto Sass, il meccanismo placeholder/allowlist, temi compilati (santorini, santorini-updated, sparta, lambda) e temi runtime (classi CMS e high-contrast), feature flag e versioning in SCSS, integrazione nell'app e nelle feature lib, e i servizi TypeScript che collegano il DOM al CSS (`ThemeService`, `FeatureStylesService`, `DirectionService`). Il lato "dati" del site theme (store NgRx, persistenza, precedenza CMS) è trattato in 13 — Site context e site theme; i breakpoint TypeScript in 18 — Layout, breakpoint, launch dialog e accessibilità; i feature toggle in generale in 42 — Feature toggle e deprecazioni.

2. Mappa dei file

PATH	RUOLO
`core-libs/styles/package.json`	Pacchetto `@spartacus/styles`, entry Sass `./_index.scss`, peer dependency Font Awesome / Open Sans / ng-select
`core-libs/styles/_index.scss`	Entry di default: `app` → `root` → `page-template` → `components`
`core-libs/styles/theme-santorini.scss`, `core-libs/styles/theme-sparta.scss`, `core-libs/styles/theme-lambda.scss`	Entry alternativi: variabili di un tema + `./index`
`core-libs/styles/scss/_core.scss`	Solo strumenti (features, versioning, functions, mixins, theme): da importare in ogni bundle
`core-libs/styles/scss/_theme.scss`	Seleziona il tema compilato (santorini)
`core-libs/styles/scss/app.scss`	Stili globali: font, Font Awesome, ng-select, blocchi cxbase, layout, misc, site theme
`core-libs/styles/scss/root.scss`	Custom property su `:root` e override a11y via classi `cxFeat_*`
`core-libs/styles/scss/_components.scss`	Allowlist, `$skipComponentStyles`, cicli `@extend %<selettore>` e `%<selettore>__body`
`core-libs/styles/scss/_page-template.scss`	Allowlist/blocklist dei page template e regole `cx-page-layout.<Template>`
`core-libs/styles/scss/_features.scss`	`getFeatureCssClass`, mixin `forFeature`
`core-libs/styles/scss/_versioning.scss`	Mixin `forVersion` (deprecato) e funzioni di versione
`core-libs/styles/scss/_site-theme.scss`	Import dei temi high-contrast
`core-libs/styles/scss/cxbase/_variables.scss`	Variabili aggiuntive rispetto a Bootstrap ("NOT a theme")
`core-libs/styles/scss/cxbase/_mixins.scss`	Mixin Bootstrap + mixin Spartacus (`type`, `weight`, `visible-focus`, …)
`core-libs/styles/scss/cxbase/functions/merge.scss`, `core-libs/styles/scss/cxbase/functions/spacer.scss`	Funzioni `mergeAll` e `spacer`
`core-libs/styles/scss/cxbase/blocks/buttons.scss` (e gli altri `blocks/*`)	Personalizzazione globale di `.btn`, form, modal, alert, …
`core-libs/styles/scss/components/index.scss`	Importa le nove aree di componenti (placeholder `%cx-*` + allowlist)
`core-libs/styles/scss/layout/_index.scss`	page-fold, ghost, screen-reader, placeholder dei page template
`core-libs/styles/scss/theme/santorini/_variables.scss`	Tema di default (+ classe `.santorini-updated`)
`core-libs/styles/scss/theme/santorini-updated/_variables.scss`	Tema aggiornato, non attivo di default
`core-libs/styles/scss/theme/sparta/_variables.scss`, `core-libs/styles/scss/theme/lambda/_variables.scss`	Temi alternativi (Lambda è un tema di test)
`core-libs/styles/scss/theme/high-contrast/high-contrast.scss` + `dark/`, `light/`, `mixins/`	Temi runtime ad alto contrasto e mixin `cx-highContrastTheme*`
`core-libs/styles/vendor/bootstrap/scss/`	Bootstrap 4.6.2 vendorizzato

PATH	RUOLO
core-libs/styles/test/scss.spec.js	Runner Jest + sass-true per i test *.spec.scss
core-libs/storefront/layout/theme/theme.service.ts, core-libs/storefront/layout/theme/theme.module.ts	Classe del site theme sul root component (APP_BOOTSTRAP_LISTENER)
core-libs/storefront/layout/direction/direction.service.ts, core-libs/storefront/layout/direction/direction.module.ts	Attributo dir su <html> (APP_INITIALIZER)
core-libs/storefront/layout/direction/config/direction.model.ts, core-libs/storefront/layout/direction/config/default-direction.config.ts	DirectionMode, Direction, default detect/rtlLanguages
core-libs/core/src/features-config/services/feature-styles.service.ts, core-libs/core/src/features-config/utils/use-feature-styles.ts	Classi cxFeat_<flag> sul root element
core-libs/storefront/layout/main/storefront.component.ts	Registra gli stili feature-flag globali; caso speciale su <html>
projects/storefrontapp/src/styles.scss, projects/storefrontapp/src/styles-config.scss, projects/storefrontapp/src/cms-themes.scss	Integrazione nell'app demo
core-libs/schematics/src/add-spartacus/index.ts	Schematic che genera styles-config.scss e gli import nel foglio principale

3. Come funziona passo per passo

3.1 Packaging e test

@spartacus/styles dichiara come dipendenza runtime soltanto hamburgers e come peer dependency @fontsource/open-sans, @fortawesome/fontawesome-free 7.1.0 e @ng-select/ng-select — core-libs/styles/package.json:L16-L24. Il pacchetto si porta dietro i sorgenti scss/ (189 file tracciati) e vendor/ (91 file) — core-libs/styles/scss/, core-libs/styles/vendor/. I test sono scritti in Sass con sass-true: un unico spec Jest cerca tutti i test/**/*.spec.scss e li esegue con sassTrue.runSass — core-libs/styles/test/scss.spec.js:L1-L15.

DA VERIFICARE: il modo in cui la build Angular risolve @import '@spartacus/styles' attraverso il campo "sass" del package.json non è verificabile qui (i sorgenti di Angular CLI non sono in /tmp/angular, che contiene solo il framework).

3.2 Entry point e ordine di import

L'entry di default core-libs/styles/_index.scss è composto da quattro import, in quest'ordine: scss/app, scss/root, scss/page-template, scss/components — core-libs/styles/_index.scss:L1-L4. Ciascuno ha un compito preciso:

- app.scss carica font, il CSS di Font Awesome, il tema di default di ng-select, cxbase/index, i blocchi cx-base (buttons, forms, modal, alert, message, tooltip, tables, card, accordion, tabs, carousel, link, dropdown), i layout cxbase, paragraph, animations, misc/* e per ultimo site-theme — core-libs/styles/scss/app.scss:L1-L39.
- root.scss emette le custom property su :root (vedi §3.5) — core-libs/styles/scss/root.scss:L1-L45.

- `_page-template.scss` emette le regole `cx-page-layout.<Template>` (vedi §3.7) — core-libs/styles/scss/_page-template.scss:L21-L27.
- `_components.scss` emette le regole per ogni elemento `cx-*` (vedi §3.6) — core-libs/styles/scss/_components.scss:L37-L53.

Esistono tre entry alternativi che antepongono le variabili di un tema: `theme-sparta.scss` (font + variabili Sparta, poi `./index`) — core-libs/styles/theme-sparta.scss:L1-L4 —, `theme-santorini.scss` (font Santorini **prima** delle variabili, poi `./index`) — core-libs/styles/theme-santorini.scss:L1-L4 — e `theme-lambda.scss` (solo variabili, nessun font) — core-libs/styles/theme-lambda.scss:L1-L3. Nessun file del repo li referenzia (vedi §9).

3.3 Il "core" Sass: strumenti senza output

`scss/_core.scss` importa features, versioning, functions, mixins e theme — core-libs/styles/scss/_core.scss:L1-L5. È ciò che ogni bundle (app o feature lib) importa per primo, perché porta variabili, funzioni e mixin senza emettere (in teoria) regole CSS:

- `_functions.scss` → `cxbase/functions`, che carica le functions del Bootstrap vendorizzato più `spacer` e `merge` — core-libs/styles/scss/_functions.scss:L1-L1, core-libs/styles/scss/cxbase/_functions.scss:L1-L3.
- `_mixins.scss` → `cxbase/mixins` + mixin high-contrast — core-libs/styles/scss/_mixins.scss:L1-L2. `cxbase/_mixins.scss` importa a sua volta `../theme`, "because of some lower level bootstrap variables", poi i mixin di Bootstrap e quelli Spartacus (reset, weight, type, button-reset, placeholder, transformations, visible-focus) — core-libs/styles/scss/cxbase/_mixins.scss:L1-L15.
- `_theme.scss` punta al tema compilato. Di default è attivo `theme/santorini/variables`; `santorini-updated` è commentato ("to uncomment on next major or with impex"), sparta e lambda pure — core-libs/styles/scss/_theme.scss:L5-L12.

In realtà il file di variabili santorini emette anche CSS (la classe `.santorini-updated`, §3.4), quindi "senza output" va preso con cautela (vedi §9).

3.4 Tema, cxbase e Bootstrap: chi vince sulle variabili

La catena delle variabili è la parte più delicata. L'ordine reale, a partire da `_theme.scss`, è:

1. **Variabili del tema** (`santorini/_variables.scss`). Il file dichiara il contratto: si possono ridefinire variabili Bootstrap, cxbase e di componente, ma non aggiungerne di nuove — core-libs/styles/scss/theme/santorini/_variables.scss:L1-L9. I colori base usano `!default` (`$primary: #1f7bc0`, `$text: #14293a`, `$visual-focus: #6d9df7`, …) — core-libs/styles/scss/theme/santorini/_variables.scss:L31-L50; `$disabled` e `$disabled-accent` sono separati per superfici chiare e riempimenti, per consentire il 7:1 nei temi high-contrast — core-libs/styles/scss/theme/santorini/_variables.scss:L53-L58. Le mappe `$theme-colors` (24 chiavi) e `$type` (scala tipografica 1–8 come coppie dimensione/peso) sono invece assegnate **senza** `!default` — core-libs/styles/scss/theme/santorini/_variables.scss:L60-L85, core-libs/styles/scss/theme/santorini/_variables.scss:L102-L112.
2. **cxbase** (`@import '../../cxbase/variables'`, "bring in variable defaults") — core-libs/styles/scss/theme/santorini/_variables.scss:L114-L115. `cxbase/_variables.scss` si autodefinisce "NOT a theme": carica le variabili Bootstrap e aggiunge solo ciò che Bootstrap non ha — core-libs/styles/scss/cxbase/_variables.scss:L1-L13. Fonde in `$theme-colors` le chiavi `background`, `text`, `inverse`, `transparent` (mettendo le chiavi del tema per seconde, quindi vincenti) e dichiara con `!default` `$font-weight-semi: 600`, `$btn-text-transform`, `$direction: ltr`, `$header-height: 67px` — core-libs/styles/scss/cxbase/_variables.scss:L15-L50. Con santorini il default di `$font-weight-semi` è ignorato: il tema, prima di im-

portare cxbase, assegna senza `!default` `$font-weight-light/normal/semi/bold` come stringhe (`'light'`, `'normal'`, `'semi'`, `'bold'`), quindi il valore effettivo è la stringa `'semi'` — core-libs/styles/scss/theme/santorini/_variables.scss:L97-L100, core-libs/styles/scss/cxbase/_variables.scss:L30-L30.

3. **Bootstrap** inizializza `$theme-colors: () !default` e poi la fonde con i propri colori, quindi le chiavi del tema già definite prevalgono — core-libs/styles/vendor/bootstrap/scss/_variables.scss:L85-L86.
4. **Override globali del tema**, scritti dopo l'import di cxbase: `$grid-gutter-width: 30px`, `$input-height: 48px`, `$body-color: $text`, `$body-bg: $inverse`, … — core-libs/styles/scss/theme/santorini/_variables.scss:L114-L145. Il tema poi rimuove da `$colors` i colori nominali di Bootstrap (indigo, purple, …, white) — core-libs/styles/scss/theme/santorini/_variables.scss:L147-L163.
5. **Flag di componente**: il tema imposta `$spinWhileLoading`, `$spinWhileWaiting`, `$zoomThumbOnHover`, `$overlayWhileLoading`, `$useTabsOnPDP`, `$useAccordionOnly` a `true !default` — core-libs/styles/scss/theme/santorini/_variables.scss:L169-L174 — mentre i file dei componenti dichiarano gli stessi flag con default `false` — core-libs/styles/scss/components/product/details/_product-images.scss:L1-L4, core-libs/styles/scss/components/content/tab-paragraph-container/_tab-paragraph-container.scss:L1-L2. Poiché il tema viene valutato per primo, l'assegnazione `false !default` del componente non ha effetto. `$useTabsOnPDP` decide a compile time se `%cx-tab-paragraph-container` estende `%pdpTabs` o `%pdpFlat` — core-libs/styles/scss/components/content/tab-paragraph-container/_tab-paragraph-container.scss:L221-L227 — e `$useAccordionOnly` se includere il mixin `accordion()` — core-libs/styles/scss/components/content/tab-paragraph-container/_tab-paragraph-container.scss:L140-L142.
6. **Classe** `.santorini-updated`: in coda al file di variabili santorini c'è un blocco CSS vero e proprio con tutte le custom property del tema aggiornato ("for impex file, remove on next major") — core-libs/styles/scss/theme/santorini/_variables.scss:L176-L215.

Gli altri temi seguono lo stesso schema con palette diverse: `santorini-updated` usa `$primary: #055f9f`, `$visual-focus: #1f3a93` e una scala tipografica ridotta (h1 = 2rem, h2 = 1.5rem) — core-libs/styles/scss/theme/santorini-updated/_variables.scss:L31-L50, core-libs/styles/scss/theme/santorini-updated/_variables.scss:L80-L86; Sparta usa `$primary: #fe5757` e `$text: #212738`, e la sua `$theme-colors` non contiene `disabled`/`disabled-accent` — core-libs/styles/scss/theme/sparta/_variables.scss:L27-L73; Lambda è un "test theme" in Comic Sans MS che assegna a `$theme-colors` solo `brand`/`accent`, chiavi che poi cxbase e Bootstrap integrano con le proprie (`background`, `text`, …, `primary`, `secondary`, …) — core-libs/styles/scss/cxbase/_variables.scss:L20-L28, core-libs/styles/vendor/bootstrap/scss/_variables.scss:L85-L86 —; usa inoltre `$cx-hamburger-type: arrow-r` — core-libs/styles/scss/theme/lambda/_variables.scss:L1-L3, core-libs/styles/scss/theme/lambda/_variables.scss:L16-L16, core-libs/styles/scss/theme/lambda/_variables.scss:L32-L52.

Font. `_fonts.scss` punta ai font Sparta, che importano i CSS di `@fontsource/open-sans` (pesi 300/400/600/700, font self-hosted) — core-libs/styles/scss/_fonts.scss:L1-L2, core-libs/styles/scss/theme/sparta/_fonts.scss:L1-L4. I font Santorini invece fanno `@import url('#{$font-url}')` verso Google Fonts — core-libs/styles/scss/theme/santorini/_fonts.scss:L1-L1, core-libs/styles/scss/theme/santorini/_variables.scss:L26-L28. Poiché `app.scss` importa `fonts` (cioè Sparta) — core-libs/styles/scss/app.scss:L2-L2 —, l'entry di default usa i font self-hosted pur compilando le variabili santorini.

3.5 Custom property su `:root`

`root.scss` è il ponte fra Sass e runtime. Per ogni voce di `$theme-colors` emette `--cx-color-<nome>` — core-libs/styles/scss/root.scss:L1-L6 — e aggiunge costanti: `--cx-page-width-max: 1140px`, i pesi `--cx-font-weight-*`, `--cx-text-transform`, `--cx-direction`, durate di transizione/animazione, border radius e `--cx-border-style` — core-libs/styles/scss/root.scss:L7-L25. `--fa-width: auto` ripristina la larghezza automatica delle icone dopo il breaking change di Font Awesome 7 — core-libs/styles/scss/root.scss:L27-L30.

Tre blocchi sono condizionati da feature flag:

- `forFeature('a11yPreventWindowsHighContrastOverride', 'currentSelector')` annidato in `:root` applica `forced-color-adjust: none` sotto `forced-colors: active` — core-libs/styles/scss/root.scss:L36-L44. Essendo `currentSelector`, il selettore risultante è `:root.cxFeat_…`, cioè la classe deve stare su `<html>` — core-libs/styles/scss/_features.scss:L57-L61.
- `.cxFeat_a11yFocusIndicatorContrast:not(.cx-theme-high-contrast-dark):not(.cx-theme-high-contrast-light)` porta `--cx-color-visual-focus` a `#1f3a93 !important` — core-libs/styles/scss/root.scss:L47-L64.
- `.cxFeat_a11yPrimaryColorContrast:not(...)` porta `--cx-color-primary` a `#055f9f !important` — core-libs/styles/scss/root.scss:L66-L70.

Altre custom property globali nascono altrove: `--cx-spatial-*` (base 0.5rem) — core-libs/styles/scss/cxbase/_spatial.scss:L1-L8 —, `--btf-delay`/`--btf-min-height`/`--btf-margin-top` per le slot sotto la piega — core-libs/styles/scss/layout/_page-fold.scss:L3-L43 —, `--cx-spinner-size` con il keyframe `spin` e il placeholder `%spinner` — core-libs/styles/scss/cxbase/_animations.scss:L1-L25 —, `--cx-color-ghost*` per lo skeleton `.ghost` — core-libs/styles/scss/layout/_ghost.scss:L1-L24.

3.6 Componenti: placeholder `%cx-*`, allowlist e `@extend`

Gli stili di un componente non sono scritti sul suo selettore, ma su un **placeholder** Sass con lo stesso nome preceduto da `%`: per esempio `%cx-site-theme-switcher` o `%cx-storefront` — core-libs/styles/scss/components/misc/site-theme-switcher/_site-theme-switcher.scss:L3-L8, core-libs/styles/scss/components/layout/_storefront.scss:L3-L10. Un placeholder non produce CSS finché qualcuno non lo estende.

`components/index.scss` importa nove aree: content, product, misc, myaccount, layout, pwa, cds, digital-payments, cpq-quote — core-libs/styles/scss/components/index.scss:L1-L9. Ogni area, oltre ai placeholder, definisce una **allowlist** `!default` di selettori:

- `$content-components-allowlist` (cx-banner, cx-link, cx-media, cx-carousel, …, cx-tab) — core-libs/styles/scss/components/content/_index.scss:L10-L14;
- `$misc-components-allowlist` (cx-table, cx-icon, cx-spinner, …, cx-site-theme-switcher, cx-read-more) — core-libs/styles/scss/components/misc/_index.scss:L13-L16;
- `$layout-components-allowlist`, che include anche l'elemento HTML `header` (placeholder `%header`) — core-libs/styles/scss/components/layout/_index.scss:L6-L7, core-libs/styles/scss/components/layout/header/_header.scss:L3-L5;
- `$product-components-allowlist`, costruita con `mergeAll` a partire da `$product-list-allowlist` — core-libs/styles/scss/components/product/index.scss:L7-L24, core-libs/styles/scss/components/product/list/_index.scss:L11-L14;
- `$myaccount-components-allowlist` (14 selettori) — core-libs/styles/scss/components/myaccount/_index.scss:L16-L22;
- le aree minori pwa, cds, digital-payments, cpq-quote — core-libs/styles/scss/components/pwa/add-to-home-screen-banner/_index.scss:L3-L3, core-libs/styles/scss/components/cds/index.scss:L3-L3, core-libs/styles/scss/components/digital-payments/index.scss:L3-L3, core-libs/styles/scss/components/cpq-quote/index.scss:L3-L3.

`_components.scss` mette tutto insieme:

1. importa `components/index` (placeholder e allowlist reali) — core-libs/styles/scss/_components.scss:L1-L2;
2. **dopo**, ridichiara `$skipComponentStyles` e tutte le 11 allowlist come `() !default`: sono fallback per le liste non definite da nessuna area del core: `$epd-visualization-components-allowlist` è definita dall'integra-

tion lib epd-visualization, mentre `$user-components-allowlist` non è definita da nessun file del repo (è un residuo e resta vuota se non la imposta il consumer) — core-libs/styles/scss/_components.scss:L4-L19, core-libs/styles/scss/_components.scss:L11-L11, integration-libs/epd-visualization/_index.scss:L5-L9;

3. unisce le 11 liste in `$selectors` con `mergeAll`, che concatena con `join` — core-libs/styles/scss/_components.scss:L21-L35, core-libs/styles/scss/cxbase/functions/merge.scss:L1-L7;
4. per ogni selettore emette `<selettore> { @extend %<selettore> !optional; }` a meno che il selettore sia in `$skipComponentStyles` — core-libs/styles/scss/_components.scss:L37-L44;
5. per lo stesso elenco fa estendere a `body` i placeholder `%<selettore>__body` — core-libs/styles/scss/_components.scss:L46-L53.

Il secondo ciclo è il canale per gli stili che un componente deve applicare **fuori da sé**, a livello di pagina. Nel core styles l'unico placeholder `__body` è `%cx-searchbox__body`, che reagisce alla classe `searchbox-is-active` messa sul body dal componente di ricerca — core-libs/styles/scss/components/product/search/_searchbox.scss:L3-L21, core-libs/storefront/cms-components/navigation/search-box/search-box.component.ts:L73-L73. La classe viene aggiunta da `setSearchBoxActive()` tramite `toggleBodyClass`, che opera su `this.winRef.document.body.classList` — core-libs/storefront/cms-components/navigation/search-box/search-box.component.ts:L470-L471, core-libs/storefront/cms-components/navigation/search-box/search-box-component.service.ts:L185-L196.

Il `!optional` rende innocuo un selettore senza placeholder corrispondente. Alcuni componenti offrono anche una classe che estende direttamente il placeholder (es. `.cx-icon { @extend %cx-icon; }`), usabile fuori dall'elemento `cx-icon` — core-libs/styles/scss/components/misc/_icons.scss:L9-L13.

Le feature lib replicano lo schema nel proprio bundle: epd-visualization importa `@spartacus/styles/scss/core`, definisce `$epd-visualization-components-allowlist` e ripete i due cicli — integration-libs/epd-visualization/_index.scss:L1-L29.

3.7 Page template

`_page-template.scss` funziona come `_components.scss`, ma per i layout di pagina: definisce `$page-template-blocklist: () !default` e `$page-template-allowlist` con 14 template — core-libs/styles/scss/_page-template.scss:L7-L19 — e per ogni template non blocklistato emette `cx-page-layout.<Template> { @extend %<Template> !optional; }` — core-libs/styles/scss/_page-template.scss:L21-L27. La classe `<Template>` su `cx-page-layout` è quella del template CMS della pagina (vedi 16 — CMS (storefront): rendering dinamico delle pagine).

I placeholder stanno in `layout/page-templates/`: `layout/_index.scss` importa page-fold, ghost, screen-reader e 13 file di template, e definisce `%CheckoutLoginPageTemplate` come estensione di `%LoginPageTemplate` — core-libs/styles/scss/layout/_index.scss:L1-L21. Le slot di base sono flex container in cui `--cx-flex-basis` (default 100%) regola la larghezza dei figli; `%LandingPage2Template` la porta al 50% per `Section2A`/`Section2B` — core-libs/styles/scss/layout/page-templates/_common-template.scss:L12-L20, core-libs/styles/scss/layout/page-templates/_landing-page-2.scss:L35-L38. `%ProductDetailsPageTemplate` usa un grid a due colonne da `lg` per la slot `Summary` — core-libs/styles/scss/layout/page-templates/_product-detail.scss:L1-L26. Le feature lib aggiungono allowlist dedicate, per esempio checkout con `$page-template-allowlist-multistep-checkout` — feature-libs/checkout/base/styles/layout/_index.scss:L5-L12.

3.8 Mixin e funzioni di base

- `spacer($key: 3)` restituisce `map-get($spacers, $key)` — core-libs/styles/scss/cxbase/functions/spacer.scss:L1-L3.
- `type($size, $weight)` legge la coppia dimensione/peso da `$type` ed emette `font-size: var(--cx-font-size, …)` e `line-height: var(--cx-line-height, …)`, delegando il peso a `weight` — core-libs/styles/scss/cxbase/mixins/_type.scss:L3-L29. `weight` traduce `light`/`semi`/`normal`/`bold` nelle custom property `--cx-font-weight-*` ed emette tale e quale un valore non stringa — core-libs/styles/scss/cxbase/mixins/_weight.scss:L1-L15. Il risultato è che ogni testo tipizzato con `type()` è sovrascrivibile a runtime con `--cx-font-size`/`--cx-line-height`.
- `visible-focus` disegna un outline `var(--cx-color-visual-focus)` di larghezza `var(--cx-visual-focus-width, 2px)` con offset 2px (−2px sotto `md`, salvo eccezioni) — core-libs/styles/scss/cxbase/mixins/_visible-focus.scss:L1-L24; `button` e `.btn` lo applicano su `:focus` — core-libs/styles/scss/cxbase/blocks/buttons.scss:L356-L361; quando l'utente usa il mouse, `%cx-storefront .mouse-focus` azzera `--cx-visual-focus-width` — core-libs/styles/scss/components/layout/_storefront.scss:L32-L44.
- Altri mixin: `button-reset`, `placeholder`, `reset($display)`, `cx-lighten`/`cx-darken` (filtro brightness) — core-libs/styles/scss/cxbase/mixins/_button-reset.scss:L1-L15, core-libs/styles/scss/cxbase/mixins/_placeholder.scss:L1-L14, core-libs/styles/scss/cxbase/mixins/_reset.scss:L1-L3, core-libs/styles/scss/cxbase/mixins/_transformations.scss:L1-L9.
- `.btn` usa `--cx-buttons-border-radius`, `--cx-text-transform`, `min-height: 48px` e `type('4')` — core-libs/styles/scss/cxbase/blocks/buttons.scss:L23-L32.
- L'hamburger usa la lib npm `hamburgers`: `$cx-hamburger-type` (default `squeeze`) seleziona il tipo e `.cx-hamburger` estende `.hamburger` e `.hamburger--<tipo>` — core-libs/styles/scss/misc/_hamburger.scss:L1-L20.

3.9 Feature flag in SCSS: `forFeature` + `FeatureStylesService`

Le modifiche stilistiche potenzialmente "breaking" sono protette da feature toggle. Il lato Sass è in `_features.scss`: `$CSS_FEATURE_FLAG_PREFIX: 'cxFeat_'` ("The same as the one used in the TS service FeatureStylesService") e `getFeatureCssClass` che lo antepone al nome — core-libs/styles/scss/_features.scss:L3-L14. Il mixin `forFeature($feature, $classTarget: 'ancestorSelector')` valida i parametri con `@error` e genera, con `@at-root`, `.cxFeat_<flag> &` (classe su un antenato) oppure, solo con `'currentSelector'`, `&.cxFeat_<flag>` (classe sull'elemento stesso, riservato al root element) — core-libs/styles/scss/_features.scss:L38-L61. Un test Sass verifica la prima forma — core-libs/styles/test/features.spec.scss:L1-L30. Nel core ci sono 39 `@include forFeature` in 19 file — core-libs/styles/scss/ (grep).

Il lato TypeScript deve mettere la classe sul DOM. `FeatureStylesService` usa lo stesso prefisso — core-libs/core/src/features-config/services/feature-styles.service.ts:L31-L36 — e un contatore per flag:

1. `useFeatureStyles(feature)` va chiamato nel costruttore del componente: richiede un injection context, chiama `registerUsage` e registra `unregisterUsage` su `DestroyRef.onDestroy` — core-libs/core/src/features-config/utils/use-feature-styles.ts:L32-L40.
2. `registerUsage` aggiunge la classe al primo utilizzo se il flag è attivo — core-libs/core/src/features-config/services/feature-styles.service.ts:L89-L95; `addClass` non fa nulla se il root element non è ancora noto — core-libs/core/src/features-config/services/feature-styles.service.ts:L130-L136.
3. Al bootstrap, `FeaturesConfigModule.forRoot` registra un `APP_BOOTSTRAP_LISTENER` che chiama `init(compRef)` — core-libs/core/src/features-config/features-config.module.ts:L41-L49; `init` memorizza l'elemento nativo del root component e aggiunge le classi già registrate (tipicamente dal costruttore del root component, che gira prima del listener) — core-libs/core/src/features-config/services/feature-styles.service.ts:L65-L77.

4. `unregisterUsage` rimuove la classe quando il contatore passa da 1 a 0 — core-libs/core/src/features-config/services/feature-styles.service.ts:L103-L115.

Angular invoca i listener `APP_BOOTSTRAP_LISTENER` con il `ComponentRef` del componente bootstrappato dopo `attachView` e un primo `tick()` — angular:packages/core/src/application/application_ref.ts:L775-L795. Nell'app demo il root component è `app-root` — projects/storefrontapp/src/app/app.component.ts:L15-L15, projects/storefrontapp/src/main.ts:L17-L17 —, quindi le classi `cxFeat_*` finiscono su `<app-root>`.

`StorefrontComponent` registra nel costruttore i flag stilistici globali (`a11yPreventWindowsHighContrastOverride`, `alignNavigationMenuWithHeader`, `cdsBottomHeaderSlotAdjustPosition`, `a11yFocusIndicatorContrast`, `a11yDisabledButtonContrast`, `a11yPrimaryColorContrast`) — core-libs/storefront/layout/main/storefront.component.ts:L117-L124 — e, per l'unico blocco su `:root`, aggiunge a mano `cxFeat_a11yPreventWindowsHighContrastOverride` su `document.documentElement` — core-libs/storefront/layout/main/storefront.component.ts:L141-L147. Un esempio d'uso a livello di componente è il bottone primario disabilitato, che con `a11yDisabledButtonContrast` usa `--cx-color-disabled-accent` — core-libs/styles/scss/cxbase/blocks/buttons.scss:L73-L84.

3.10 Versioning SCSS (`forVersion`, deprecato)

Prima dei feature flag nominati, Spartacus usava un versioning degli stili. `_versioning.scss` si apre con un avviso: `forVersion($level)` è deprecato e superato da `forFeature` — core-libs/styles/scss/_versioning.scss:L1-L3. La versione corrente è `$_fullVersion: (major: 221121, minor: 22, patch: 0)` con `$_majorVersion: 2211` — core-libs/styles/scss/_versioning.scss:L29-L37; il consumer può impostare `$styleVersion` (default `$_majorVersion`) e `$useLatestStyles` (default `false`) — core-libs/styles/scss/_versioning.scss:L39-L46. `forVersion($from, $to: 0)` (`@deprecated since 2211.20`) emette il contenuto solo se `$from` non supera la versione corrente e la versione è "stabile e valida" o è un breaking change richiesto — core-libs/styles/scss/_versioning.scss:L63-L77; i breaking change sono richiesti se `$useLatestStyles` è vero o `$styleVersion` supera `$_majorVersion` — core-libs/styles/scss/_versioning.scss:L228-L231. Nel core, `@include forVersion` compare solo nel commento d'esempio; il meccanismo resta coperto dai test — core-libs/styles/scss/_versioning.scss:L18-L18, core-libs/styles/test/versioning-test-util.scss:L1-L10.

3.11 Integrazione nell'applicazione

Il foglio principale dell'app demo importa, con commenti "ORDER IMPORTANT": `styles-config`, `@spartacus/styles/scss/core`, 15 parziali del Bootstrap vendorizzato, `@spartacus/styles` e infine `cms-themes` — projects/storefrontapp/src/styles.scss:L1-L29. L'ordine conta:

- `styles-config` viene prima di tutto perché contiene le variabili del consumer, che devono precedere le assegnazioni `!default` della libreria; nell'app demo imposta `$useLatestStyles: true` — projects/storefrontapp/src/styles-config.scss:L1-L2.
- `scss/core` prima di Bootstrap, perché i parziali Bootstrap leggono le variabili già personalizzate dal tema.
- `cms-themes` per ultimo: il commento di `styles.scss` dice che serve a far vincere le custom property `--cx-color-*` delle classi `.santorini`, `.lambda`, `.sparta` sui default di `:root`, ma rispetto a `:root` vincerebbero comunque, perché la classe è messa sul root component (un discendente di `<html>`) — core-libs/storefront/layout/theme/theme.service.ts:L52-L58. L'ordine conta contro le altre regole che dichiarano le stesse proprietà sullo **stesso** root component con pari specificità, come gli override `.cxFeat_*` di `root.scss`, che per questo usano `!important` — core-libs/styles/scss/root.scss:L55-L57, projects/storefrontapp/src/styles.scss:L27-L29, projects/storefrontapp/src/cms-themes.scss:L1-L60. L'app demo abilita `applyBaseSiteThemeFromCms`, quindi la classe arriva dal campo `theme` del base site — projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L378-L385.

Ogni feature lib ha un bundle CSS separato in `project.json` (es. `lib-asm.scss` → bundle `asm`) e l'app silenzia la deprecazione Sass di `@import` — projects/storefrontapp/project.json:L43-L54, projects/storefrontapp/project.json:L137-L141. Quasi tutti i bundle (21 su 24) ripartono da `styles-config` e dall'entry della lib — projects/storefrontapp/src/styles/lib-cart.scss:L1-L2 —; `lib-customer-ticketing`, `lib-s4om` e `lib-subscription-billing` importano solo l'entry della lib, quindi lì non arriva neppure `styles-config` — projects/storefrontapp/src/styles/lib-customer-ticketing.scss:L1-L1. L'entry della lib, che a sua volta reimporta `@spartacus/styles/scss/core` più eventuali blocchi cxbase — feature-libs/cart/_index.scss:L1-L3. Ogni bundle è quindi una compilazione Sass indipendente: le variabili impostate nel foglio principale non arrivano nei bundle delle lib, a meno di stare in `styles-config`.

Nelle app nuove, lo schematic `add-spartacus` crea `styles-config.scss` con `$styleVersion: <featureLevel>` (default: major.minor della versione corrente) — core-libs/schematics/src/add-spartacus/index.ts:L70-L86, core-libs/schematics/src/shared/utils/package-utils.ts:L147-L149 — e inserisce nel foglio principale la stessa sequenza (config, core, Bootstrap, `@spartacus/styles/index`); con `--theme` aggiunge `@import '@spartacus/styles/scss/theme/${options.theme}'` — core-libs/schematics/src/add-spartacus/index.ts:L146-L173. L'opzione `theme` è una stringa libera ("E.g: santorini") — core-libs/schematics/src/add-spartacus/schema.json:L386-L389. Per gli schematics in generale vedi 43 — Schematics e migrazioni di Spartacus.

3.12 Site theme lato CSS: temi high-contrast

`app.scss` include per ultimo `_site-theme.scss`, che carica le variabili dei due temi ad alto contrasto e `high-contrast.scss` — core-libs/styles/scss/_site-theme.scss:L1-L3. `.cx-theme-high-contrast-dark` ridefinisce le custom property (`--cx-color-text: #ffffff`, `--cx-color-background: #000000`, `--cx-color-primary: #6bd3ff`, …) — core-libs/styles/scss/theme/high-contrast/dark/_variables.scss:L1-L27 —, `.cx-theme-high-contrast-light` usa testo nero su bianco con `--cx-color-primary: #004ccb` — core-libs/styles/scss/theme/high-contrast/light/_variables.scss:L1-L26 — e `high-contrast.scss` applica `color` e `background-color` a entrambe le classi — core-libs/styles/scss/theme/high-contrast/high-contrast.scss:L1-L5.

Dove le sole custom property non bastano, i componenti usano `cx-highContrastTheme($feature: null)`: senza flag genera `.cx-theme-high-contrast-dark &, .cx-theme-high-contrast-light &` annidato; con un flag usa `@at-root` per la forma combinata `.cx-theme-high-contrast-dark.cxFeat_<flag> &`; esistono varianti `-dark` e `-light` — core-libs/styles/scss/theme/high-contrast/mixins/_mixins.scss:L1-L40. Compare 67 volte nel core — `core-libs/styles/scss/` (grep). `%cx-storefront` disattiva i forced colors di Windows quando porta una delle classi high-contrast — core-libs/styles/scss/components/layout/_storefront.scss:L52-L59.

3.13 Site theme lato TypeScript: `ThemeService`

La catena che porta la classe sul DOM:

1. `BaseCoreModule` importa `SiteThemeModule.forRoot()`, che fornisce `SiteThemeService`, la config di default e un `APP_INITIALIZER` che chiama `SiteThemeInitializer.initialize()` — core-libs/core/src/base-core.module.ts:L43-L43, core-libs/core/src/site-theme/site-theme.module.ts:L18-L29, core-libs/core/src/site-theme/providers/site-theme-initializer-providers.ts:L10-L23.
2. `initialize` attende la config `context` stabile, ripristina il valore persistito e imposta il default se non inizializzato; con `applyBaseSiteThemeFromCms` segue anche `BaseSite.theme` — core-libs/core/src/site-theme/services/site-theme-initializer.ts:L36-L50 — con precedenza: `config.context.theme` statico, poi tema opzionale scelto dall'utente, poi tema CMS — core-libs/core/src/site-theme/services/site-theme-initializer.ts:L93-L127. Il default arriva da `getDefaultClassName` — core-libs/core/src/site-theme/facade/site-theme.service.ts:L46-L63 — e i temi opzionali di default sono i due high-contrast — core-libs/core/src/site-theme/config/default-site-theme-config.ts:L9-L22.

3. `setActive` fa dispatch di `SetActiveSiteTheme` solo se la classe cambia ed è valida — core-libs/core/src/site-theme/facade/site-theme.service.ts:L109-L119; `getActive()` legge `getActiveSiteTheme` dallo store filtrando i null — core-libs/core/src/site-theme/facade/site-theme.service.ts:L99-L104.
4. `LayoutModule` (importato da `BaseStorefrontModule`) importa `ThemeModule` — core-libs/storefront/layout/layout.module.ts:L15-L25, core-libs/storefront/base-storefront.module.ts:L40-L47 —, che registra `initTheme` come `APP_BOOTSTRAP_LISTENER` — core-libs/storefront/layout/theme/theme.module.ts:L10-L25.
5. `ThemeService.init` crea un `Renderer2`, memorizza il root component e sottoscrive `getActive()` — core-libs/storefront/layout/theme/theme.service.ts:L35-L46; `setTheme` rimuove la classe precedente e aggiunge la nuova se non vuota — core-libs/storefront/layout/theme/theme.service.ts:L52-L61.
6. L'utente può cambiare tema da `SiteThemeSwitcherComponent`, che scrive la scelta con `setActive` e registra `useFeatureStyles('a11ySiteContextCaretClick')` — core-libs/storefront/cms-components/misc/site-theme-switcher/site-theme-switcher.component.ts:L44-L60, core-libs/storefront/cms-components/misc/site-theme-switcher/site-theme-switcher.component.service.ts:L14-L25.

Il risultato è che il root component porta contemporaneamente la classe del tema (es. `santorini` o `cx-theme-high-contrast-dark`) e le classi `cxFeat_*`. È per questo che `root.scss` deve usare `!important` per battere `.santorini`, caricata dopo con la stessa specificità, e le guardie `:not(.cx-theme-high-contrast-*)` per non toccare i temi high-contrast — core-libs/styles/scss/root.scss:L47-L64.

3.14 Direzione (RTL)

`DirectionMode` ha solo `LTR = 'ltr'` e `RTL = 'rtl'`; il valore HTML5 `auto` non è supportato perché "too fragile" — core-libs/storefront/layout/direction/config/direction.model.ts:L7-L23. La config `direction` (`default`, `detect`, `rtlLanguages`, `ltrLanguages`, tutte opzionali) — core-libs/storefront/layout/direction/config/direction.model.ts:L29-L56 — è esposta da `DirectionConfig`, classe astratta `useExisting: Config` con module augmentation — core-libs/storefront/layout/direction/config/direction.config.ts:L25-L35. Il default è `detect: true`, `default: LTR`, `rtlLanguages: ['he', 'ar']` — core-libs/storefront/layout/direction/config/default-direction.config.ts:L10-L19.

Flusso:

1. `LayoutModule` importa `DirectionModule` — core-libs/storefront/layout/layout.module.ts:L15-L25 —, che registra un `APP_INITIALIZER` (`initHtmlDirAttribute`) che restituisce la Promise di `DirectionService.initialize()` — core-libs/storefront/layout/direction/direction.module.ts:L12-L35. `APP_INITIALIZER` è deprecato in Angular dalla v19 a favore di `provideAppInitializer` — angular:packages/core/src/application/application_init.ts:L36-L42.
2. `initialize()` converte con `lastValueFrom` la config stabile `direction`: se `detect` chiama `detect()`, altrimenti imposta `config.default` su `document.documentElement` — core-libs/storefront/layout/direction/direction.service.ts:L46-L62.
3. `detect()` (protetto da `startsDetecting`) sottoscrive `LanguageService.getActive()` e a ogni lingua imposta `dir` — core-libs/storefront/layout/direction/direction.service.ts:L68-L83.
4. `getDirection` controlla `rtlLanguages`, poi `ltrLanguages`, poi `default` — core-libs/storefront/layout/direction/direction.service.ts:L104-L112; `setDirection` imposta l'attributo o lo rimuove se `undefined` — core-libs/storefront/layout/direction/direction.service.ts:L89-L95.
5. `ngOnDestroy` disiscrive "to avoid memory leaks in SSR" — core-libs/storefront/layout/direction/direction.service.ts:L114-L117.

Il CSS reagisce soprattutto con proprietà logiche (216 righe con `*-inline-start`/`*-inline-end` e nessuna proprietà fisica `margin|padding-left|right`: le sole occorrenze sono il nome della custom property `--cx-margin-right`) — `core-libs/styles/scss/` (grep), core-libs/styles/scss/components/content/video/_video.

scss:L19-L19, core-libs/styles/scss/cxbase/blocks/alert.scss:L26-L26, core-libs/styles/scss/cxbase/blocks/message.scss:L61-L61 — e, dove serve, con selettori `[dir='rtl']`: icone con `flip-at-rtl`/`flip-at-ltr`, separatore del breadcrumb, verso delle stelle di rating — core-libs/styles/scss/components/misc/_icons.scss:L1-L7, core-libs/styles/scss/components/content/navigation/_breadcrumb.scss:L1-L3, core-libs/styles/scss/components/product/_star-rating.scss:L35-L38. `IconComponent` espone le due classi come `@HostBinding` "for the style layer" — core-libs/storefront/cms-components/misc/icon/icon.component.ts:L69-L77. La lingua attiva è descritta in 13 — Site context e site theme e in 37 — Internazionalizzazione (i18n).

3.15 Breakpoint: Sass vs TypeScript

I breakpoint Sass di Bootstrap sono valori **minimi**: xs 0, sm 576px, md 768px, lg 992px, xl 1200px — core-libs/styles/vendor/bootstrap/scss/_variables.scss:L207-L213. Il `defaultLayoutConfig` TypeScript usa numeri xs 576, sm 768, md 992, lg 1200, xl `{min: 1200}`, e `BreakpointService` tratta i numeri come larghezza **massima** — core-libs/storefront/layout/config/default-layout.config.ts:L9-L19, core-libs/storefront/layout/breakpoint/breakpoint.service.ts:L161-L176. Le due scale coincidono come confini ma sono sfalsate di un nome (vedi §9 e 18 — Layout, breakpoint, launch dialog e accessibilità).

---

5. Estratti di codice reale

5.1 Emissione dei componenti

core-libs/styles/scss/_components.scss:L1-L19 (estratto)

```scss
@import './functions';
@import './components/index';

// the $skipComponentStyles is used as a list of component styles that can be ignore
// during the sass compilation. Whenever the list contains a component selector, the
// selector is not used.
$skipComponentStyles: () !default;

$layout-components-allowlist: () !default;
$product-components-allowlist: () !default;
// ...
$cpq-quote-allowlist: () !default;
```

core-libs/styles/scss/_components.scss:L37-L53

```scss
@each $selector in $selectors {
  #{$selector} {
    // skip selectors if they're added to the $skipComponentStyles list
    @if (index($skipComponentStyles, $selector) ==null) {
      @extend %#{$selector} !optional;
    }
  }
}

// add body specific selectors
body {
  @each $selector in $selectors {
    @if (index($skipComponentStyles, $selector) ==null) {
      @extend %#{$selector}__body !optional;
```

```
    }
  }
}
```

5.2 Page template

core-libs/styles/scss/_page-template.scss:L7-L27

```scss
// The $page-template-blocklist can be used to prevent template CSS
// being generated.
$page-template-blocklist: () !default;

// allowlisted page template selectors are processed
// unless (some) that are blocklisted using `$page-template-blocklist`
$page-template-allowlist:
  LandingPage2Template, ContentPage1Template, CategoryPageTemplate,
  ProductListPageTemplate, ProductGridPageTemplate,
  SearchResultsListPageTemplate, ProductDetailsPageTemplate, LoginPageTemplate,
  MultiStepCheckoutSummaryPageTemplate, ErrorPageTemplate,
  CheckoutLoginPageTemplate, AccountPageTemplate, OrderConfirmationPageTemplate,
  MyAccountViewPageTemplate !default;

@each $selector in $page-template-allowlist {
  cx-page-layout.#{$selector} {
    @if (index($page-template-blocklist, $selector) == null) {
      @extend %#{$selector} !optional;
    }
  }
}
```

5.3 `:root` e gli override a11y

core-libs/styles/scss/root.scss:L1-L16 (estratto)

```scss
@import 'theme';

:root {
  @each $color, $value in $theme-colors {
    --cx-color-#{$color}: #{$value};
  }
  --cx-page-width-max: 1140px;

  --cx-font-weight-light: 300;
  // ...
  --cx-direction: #{$direction};
```

core-libs/styles/scss/root.scss:L55-L70

```scss
// `!important` is required because CMS theme classes (e.g. `.santorini`) also
// set this property on the same element with equal specificity and are loaded
// afterwards, so they would otherwise win. The `:not()` guards exclude the
// high-contrast themes, which define their own compliant focus colors that
// must not be overridden.
.#{getFeatureCssClass('a11yFocusIndicatorContrast')}:not(
    .cx-theme-high-contrast-dark
  ):not(.cx-theme-high-contrast-light) {
  --cx-color-visual-focus: #1f3a93 !important;
}

.#{getFeatureCssClass('a11yPrimaryColorContrast')}:not(
    .cx-theme-high-contrast-dark
  ):not(.cx-theme-high-contrast-light) {
  --cx-color-primary: #055f9f !important;
}
```

5.4 Il mixin `forFeature`

core-libs/styles/scss/_features.scss:L41-L62

```scss
@mixin forFeature($feature, $classTarget: 'ancestorSelector') {
  // Validate params
  @if (type-of($feature) != 'string') {
    @error "forFeature: $feature param must be a string, but #{type-of($feature)} was provided.";
  }
  @if (not index(('ancestorSelector', 'currentSelector'), $classTarget)) {
    @error "forFeature: $classTarget must be either 'ancestorSelector' or 'currentSelector', but #
{$classTarget} was provided.";
  }
  // Validate params end

  $featureClass: getFeatureCssClass($feature);
  @if ($classTarget == 'ancestorSelector') {
    @at-root .#{$featureClass} & {
      @content;
    }
  }
  @if ($classTarget == 'currentSelector') {
    @at-root &.#{$featureClass} {
      @content;
    }
  }
}
```

5.5 Il contatore di `FeatureStylesService`

core-libs/core/src/features-config/services/feature-styles.service.ts:L89-L115

```ts
registerUsage(feature: FeatureToggleKey): void {
  const currentCounter = this.usagesCounter.get(feature) ?? 0;
  if (this.isEnabled(feature) && currentCounter === 0) {
    this.addClass(feature);
  }
  this.usagesCounter.set(feature, currentCounter + 1);
}

/**
 * Unregisters the usage of a feature flag.
 *
 * If the feature flag is enabled, this method removes the feature's CSS class
 * from the root element (unless there are other registered usages of the same feature yet).
 */
unregisterUsage(feature: FeatureToggleKey): void {
  const currentCounter = this.usagesCounter.get(feature) ?? 0;
  if (currentCounter === 0 && isDevMode()) {
    this.logger.warn(
      `Feature flag CSS: "${feature}" is already not used, so it cannot be unregistered.`
    );
  }

  if (this.isEnabled(feature) && currentCounter === 1) {
    this.removeClass(feature);
  }
  this.usagesCounter.set(feature, Math.max(currentCounter - 1, 0));
}
```

5.6 ThemeService

core-libs/storefront/layout/theme/theme.service.ts:L35-L61

```ts
init(rootComponent: ComponentRef<any>): void {
  this.renderer = this.rendererFactory.createRenderer(null, null);
  this.rootComponent = rootComponent;
  // Theme value is a string. It is put in the generic multi-value
  // property of the SiteContextConfig. So the array's first item
  // is the theme value.
  this.subscription.add(
    this.siteThemeService
      .getActive()
      .subscribe((activeTheme) => this.setTheme(activeTheme))
  );
}

ngOnDestroy(): void {
  this.subscription.unsubscribe();
}
```

```
  setTheme(theme: string | undefined): void {
    const element = this.rootComponent.location.nativeElement;
    if (this.existingTheme) {
      this.renderer.removeClass(element, this.existingTheme);
    }
    if (theme) {
      this.renderer.addClass(element, theme);
      this.existingTheme = theme;
    }
  }
```

5.7 DirectionService

core-libs/storefront/layout/direction/direction.service.ts:L46-L62

```ts
  initialize(): Promise<any> {
    return lastValueFrom(
      this.configInit.getStable('direction').pipe(
        tap((config: DirectionConfig) => {
          this.config = config?.direction;
          if (this.config?.detect) {
            this.detect();
          } else {
            this.setDirection(
              this.winRef.document.documentElement,
              this.config?.default
            );
          }
        })
      )
    );
  }
```

core-libs/storefront/layout/direction/direction.service.ts:L104-L112

```ts
  getDirection(language?: string): DirectionMode | undefined {
    if (language && this.config?.rtlLanguages?.includes(language)) {
      return DirectionMode.RTL;
    }
    if (language && this.config?.ltrLanguages?.includes(language)) {
      return DirectionMode.LTR;
    }
    return this.config?.default;
  }
```

5.8 Integrazione nell'app demo

projects/storefrontapp/src/styles.scss:L1-L29 (estratto)

```scss
@import 'styles-config';

// ORDER IMPORTANT: Spartacus core first
@import '@spartacus/styles/scss/core';

// ORDER IMPORTANT: Bootstrap next

@import '@spartacus/styles/vendor/bootstrap/scss/reboot';
// ...
@import '@spartacus/styles/vendor/bootstrap/scss/tooltip';

// ORDER IMPORTANT: Spartacus styles last
@import '@spartacus/styles';

// CMS-driven base-site theme rules (must come after Spartacus styles so
// the CSS custom properties override the defaults in `:root`).
@import 'cms-themes';
```

5.9 Il tema compilato e i suoi flag

core-libs/styles/scss/_theme.scss:L5-L12

```scss
//point to the theme variables
//@import 'theme/sparta/variables';
//@import "theme/lambda/variables";

//old theme to be commented out on next major or with impex
@import 'theme/santorini/variables';
// new theme below to uncomment on next major or with impex
// @import 'theme/santorini-updated/variables';
```

core-libs/styles/scss/components/content/tab-paragraph-container/_tab-paragraph-container.scss:L221-L227

```scss
%cx-tab-paragraph-container {
  @if $useTabsOnPDP == true {
    @extend %pdpTabs !optional;
  } @else {
    @extend %pdpFlat !optional;
  }
  @extend %cx-tab !optional;
```

5.10 Ridefinizione di un mixin in una feature lib

feature-libs/cart/_index.scss:L1-L11

```scss
@import '@spartacus/styles/scss/core';
@import '@spartacus/styles/scss/cxbase/blocks/modal';
@import '@spartacus/styles/scss/misc/table';

@mixin visible-focus {
  outline-style: solid;
  outline-color: var(--cx-color-visual-focus);
  outline-width: var(--cx-visual-focus-width, 2px);
  outline-offset: 4px;
  transition: none;
}
```

7. Commenti e note notevoli dal sorgente

- "🚨 CAUTION. The approach of using `forVersion($level)` in this file is deprecated and superseded by the recommendation of using named feature flags with mixin `forFeature($featureName)`." — `core-libs/styles/scss/_versioning.scss:L1-L3`; e `@deprecated since 2211.20, use forFeature($feature) mixin instead` — `core-libs/styles/scss/_versioning.scss:L63-L63`. Il versioning numerico è ancora nel pacchetto (e nei test) ma non va usato per nuovi stili.
- "IMPORTANT: Please mind to call `useFeatureStyles(feature)` from `@spartacus/core` in the constructor of your styled component. Otherwise the feature-flagged styles MIGHT NOT be activated EVEN if the flag is enabled" — `core-libs/styles/scss/_features.scss:L16-L31`. È il punto di contatto obbligatorio fra SCSS e TypeScript.
- "The second argument with value `'currentSelector'` should be passed ONLY in one edge case, when the feature-flagged styles are defined for the Angular root element, i.e. `app-root`." — `core-libs/styles/scss/_features.scss:L38-L40`.
- "TODO: Required to use feature flag with root styles. Remove this entire block once the a11yPreventWindowsHighContrastOverride feature flag is removed" — `core-libs/storefront/layout/main/storefront.component.ts:L141-L142`.
- Commento sul `!important` di `--cx-color-visual-focus`: spiega WCAG 1.4.11 (≥3:1) e la competizione con `.santorini` caricata dopo — `core-libs/styles/scss/root.scss:L47-L59`.
- "This is NOT a theme. This file should include ONLY new variables that Bootstrap does not provide." — `core-libs/styles/scss/cxbase/_variables.scss:L1-L13`.
- "You can: 1) Set new values for Bootstrap variables ... You cannot: 1) Add new variables" — `core-libs/styles/scss/theme/santorini/_variables.scss:L1-L9`.
- "old theme to be commented out on next major or with impex" / "new theme below to uncomment on next major or with impex" — `core-libs/styles/scss/_theme.scss:L9-L12`; e "santorini-updated variables for impex file, remove on next major" — `core-libs/styles/scss/theme/santorini/_variables.scss:L176-L176`. Il passaggio a santorini-updated è pianificato ma non ancora fatto.
- "TODO: Replace `$font-url` with swap url in 5.0 to use swap strategy by default." — `core-libs/styles/scss/theme/santorini/_variables.scss:L26-L26`: TODO storico mai chiuso.
- `// TODO (#11607) remove LoginPageTemplate from allowlist` — `core-libs/styles/scss/_page-template.scss:L5-L5`.
- "this change is not kicking-in, minor issue, it does work work when unwraping, unwrap in next major" — `core-libs/styles/scss/components/layout/_storefront.scss:L37-L37`, accanto alla regola `.mouse-focus`.
- "Font Awesome breaking change on v7: Fixed Width is now default for icons." — `core-libs/styles/scss/root.scss:L27-L29`.
- "The HTML5 "auto" value is not supported in Spartacus, as it's considered to be too fragile" — `core-libs/storefront/layout/direction/config/direction.model.ts:L11-L12`.
- "we don't export the factory to avoid a breaking change when we drop the initHtmlDirAttribute" — `core-libs/storefront/layout/direction/index.ts:L9-L9`.
- "Cleans up the subscription, to avoid memory leaks in SSR." — `core-libs/storefront/layout/direction/direction.service.ts:L115-L115`.
- "Note: The default Site Theme can be driven by the CMS, but additional possible selectable themes (like a11y high contrast themes) can be configured only in the separate Spartacus configuration `config.siteTheme.optionalThemes`." — `core-libs/core/src/site-context/config/config-loader/site-context-config-initializer.ts:L90-L93`.

8. Extension point

EXTENSION POINT	LIVELLO	COME SI USA	RIFERIMENTO
Variabili tema (`$primary`, `$theme-colors`, `$type`, `$font-url`, flag di componente)	Sass, compile time	Assegnarle in `styles-config.scss` (prima di `scss/core`) per le `!default`; per le mappe senza `!default` vedi §9	`core-libs/styles/scss/theme/santorini/_variables.scss:L28-L174`
`$skipComponentStyles`	Sass	Lista di selettori `cx-*` per cui non emettere lo stile di libreria (per riscriverlo da zero)	`core-libs/styles/scss/_components.scss:L4-L7`
`$<area>-components-allowlist`	Sass	Ridefinire la lista prima dell'import per restringere o ampliare i selettori emessi	`core-libs/styles/scss/components/content/_index.scss:L10-L14`, `core-libs/styles/scss/_components.scss:L9-L19`
`$page-template-allowlist` / `$page-template-blocklist`	Sass	Escludere o aggiungere page template; un template nuovo richiede anche il suo placeholder `%<Template>`	`core-libs/styles/scss/_page-template.scss:L7-L27`
Placeholder `%cx-*`, `%cx-*__body`, `%<Template>`	Sass	Aggiungere regole al placeholder dopo l'import di `scss/core`, oppure creare il placeholder di un componente custom e aggiungerne il selettore alla allowlist	`core-libs/styles/scss/_components.scss:L37-L53`
Custom property `--cx-*`	CSS runtime	Ridefinirle su `:root` o su una classe tema (pattern di `cms-themes.scss`)	`core-libs/styles/scss/root.scss:L3-L45`, `projects/storefrontapp/src/cms-themes.scss:L1-L60`
Classi tema (`.santorini`, `.cx-theme-high-contrast-*`, temi custom)	CSS + config	Aggiungere un tema a `siteTheme.optionalThemes` e la classe CSS corrispondente; oppure `context.theme` / `BaseSite.theme`	`core-libs/core/src/site-theme/config/default-site-theme-config.ts:L9-L22`
Mixin `forFeature`, `cx-highContrastTheme*`, `visible-focus`, `type`, `weight`	Sass	Riusarli negli stili custom; ridefinirli dopo `scss/core` (come fa cart con `visible-focus`)	`core-libs/styles/scss/_features.scss:L41-L62`, `core-libs/styles/scss/theme/high-contrast/mixins/_mixins.scss:L1-L40`, `feature-libs/cart/_index.scss:L5-L11`
`useFeatureStyles`, `FeatureStylesService`	TS (`@spartacus/core`)	Chiamare `useFeatureStyles` nel costruttore dei componenti custom con stili `forFeature`	`core-libs/core/src/features-config/utils/use-feature-styles.ts:L32-L40`
`ThemeService` (`init`, `setTheme`), `ThemeModule`	TS (`@spartacus/storefront`)	Sostituire il servizio via DI per mettere la classe su un altro elemento	`core-libs/storefront/layout/theme/theme.service.ts:L18-L62`
`DirectionConfig`, `DirectionService` (`setDirection`, `getDirection`, `detect`)	TS (`@spartacus/storefront`)	`provideConfig({ direction: { … } })` o sostituzione del servizio (es. match su prefisso lingua)	`core-libs/storefront/layout/direction/config/direction.config.ts:L25-L35`, `core-libs/storefront/layout/direction/direction.service.ts:L28-L118`
`$styleVersion`, `$useLatestStyles`	Sass (deprecato)	Solo per stili legacy con `forVersion`	`core-libs/styles/scss/_versioning.scss:L39-L46`

Ricette pratiche (Parte III):

- Override SCSS, placeholder, allowlist/skip e temi custom: 53 — Ricette: feature lib lazy, carrello/checkout, stili, traduzioni.
- Configurazione `direction` e `siteTheme` con `provideConfig`, sostituzione di servizi come `ThemeService`/`DirectionService` via DI: 50 — Ricette: configurazione, DI, interceptor, eventi.
- Stili di un componente CMS custom e di nuovi page template/layout: 51 — Ricette: componenti CMS, outlet, route e layout.
- Cosa è API pubblica (custom property, variabili `!default`) e cosa è dettaglio interno (struttura dei file SCSS) in vista degli upgrade: 54 — API pubblica vs interna, upgrade, anti-pattern, checklist.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. **Le allowlist vanno ridefinite PRIMA dell'import.** In `_components.scss` le dichiarazioni `() !default` vengono dopo `@import './components/index'`, quindi sono solo fallback; e le allowlist delle aree sono `!default`. Per cambiarne una bisogna assegnarla prima di importare `@spartacus/styles` (es. in `styles-config`) — `core-libs/styles/scss/_components.scss:L1-L19`, `core-libs/styles/scss/components/content/_index.scss:L10-L14`.
2. `$skipComponentStyles` **non elimina tutto.** Filtra solo l'`@extend` sull'elemento: classi che estendono direttamente il placeholder (es. `.cx-icon`) restano emesse — `core-libs/styles/scss/_components.scss:L37-L44`, `core-libs/styles/scss/components/misc/_icons.scss:L9-L11`.
3. **Template senza CSS.** `%SearchResultsGridPageTemplate` esiste ma `SearchResultsGridPageTemplate` non è in `$page-template-allowlist`, quindi il suo CSS non viene generato di default, pur esistendo il template nel layout TS — `core-libs/styles/scss/layout/page-templates/_search-results-grid.scss:L1-L1`, `core-libs/styles/scss/_page-template.scss:L13-L19`, `core-libs/storefront/recipes/config/layout-config.ts:L88-L88`.
4. **Selettori in allowlist senza placeholder.** `cx-page-header` è in `$content-components-allowlist` ma esiste solo la classe `.cx-page-header`; `!optional` evita l'errore — `core-libs/styles/scss/components/content/_index.scss:L13-L13`, `core-libs/styles/scss/cxbase/layout/page.scss:L7-L11`. Analogamente `MultiStepCheckoutSummaryPageTemplate` è nell'allowlist core ma il placeholder sta nel bundle della lib checkout — `core-libs/styles/scss/_page-template.scss:L17-L17`, `feature-libs/checkout/base/styles/layout/_index.scss:L9-L12`.
5. **Bundle indipendenti.** Ogni bundle di feature lib è una compilazione separata che riparte da `scss/core` e, in 21 bundle su 24, da `styles-config` (non in `lib-customer-ticketing`, `lib-s4om`, `lib-subscription-billing`): una variabile impostata solo nel foglio principale non arriva nei bundle delle lib — `projects/storefrontapp/src/styles/lib-cart.scss:L1-L2`, `projects/storefrontapp/src/styles/lib-customer-ticketing.scss:L1-L1`, `feature-libs/cart/_index.scss:L1-L3`. Inoltre le lib possono ridefinire mixin core: cart ridefinisce `visible-focus` con `outline-offset: 4px`, quindi il focus nel bundle cart differisce da quello core — `feature-libs/cart/_index.scss:L5-L11`, `core-libs/styles/scss/cxbase/mixins/_visible-focus.scss:L1-L7`.
6. **Mappe senza** `!default`**.** `$theme-colors` e `$type` nei temi sono assegnate senza `!default`; poiché `_theme.scss` viene reimportato da molti file (circa 20 file sotto `scss/` importano `../../theme` o simili), un valore del consumer per queste mappe impostato in `styles-config` verrebbe sovrascritto dal reimport. DA VERIFICARE con una compilazione reale (con `@import` Sass non deduplica i file) — `core-libs/styles/scss/theme/santorini/_variables.scss:L60-L112`, `core-libs/styles/scss/cxbase/layout/app.scss:L1-L1`. Per lo stesso motivo la classe `.santorini-updated` potrebbe essere emessa più volte — `core-libs/styles/scss/theme/santorini/_variables.scss:L177-L215`.

7. **Entry** `theme-*.scss` **probabilmente inefficaci.** Caricano le variabili del tema e poi `./index`, che reimporta `_theme` → santorini: le `!default` del primo tema restano, ma le assegnazioni senza `!default` di santorini (`$theme-colors`, `$type`, …) le sovrascrivono; per Lambda la mappa `brand`/`accent` andrebbe persa e, anzi, il file di variabili importa `cxbase/mixins` → `../theme` → santorini **prima** dei propri colori, quindi le `!default` di Lambda (`$primary: #987654 !default`, …) non prevalgono neppure al primo import — core-libs/styles/scss/theme/lambda/_variables.scss:L12-L19, core-libs/styles/scss/cxbase/_mixins.scss:L5-L5, core-libs/styles/scss/_theme.scss:L10-L10 —; per Sparta mancherebbero comunque `disabled`/`disabled-accent` nella sua mappa. DA VERIFICARE con compilazione — core-libs/styles/theme-lambda.scss:L1-L3, core-libs/styles/scss/root.scss:L1-L1, core-libs/styles/scss/theme/sparta/_variables.scss:L50-L73. Nessun file del repo referenzia questi entry.
8. **Ordine font/variabili in** `theme-santorini.scss`**.** Il file dei font (che usa `$font-url`) è importato prima delle variabili che lo definiscono. DA VERIFICARE: senza compilazione non è confermato se Sass segnali variabile non definita quando il consumer non la imposta prima — core-libs/styles/theme-santorini.scss:L1-L2, core-libs/styles/scss/theme/santorini/_fonts.scss:L1-L1, core-libs/styles/scss/theme/santorini/_variables.scss:L28-L28.
9. `--theme` **dello schematic.** Con `--theme=<x>` lo schematic aggiunge `@import '@spartacus/styles/scss/theme/<x>'`, ma `scss/theme/santorini/` contiene solo `_fonts.scss` e `_variables.scss`, nessun `_index.scss`. DA VERIFICARE se l'import si risolve — core-libs/schematics/src/add-spartacus/index.ts:L170-L172.
10. `$styleVersion` **dello schematic.** Il default generato è nel formato `221121.22`, mentre `$_majorVersion` è `2211`: `compareVersion` lo considera maggiore, quindi `useBreakingChanges()` risulta vero. Effetto pratico nullo nel core, dove `forVersion` non è più usato. DA VERIFICARE con compilazione — core-libs/schematics/src/add-spartacus/index.ts:L74-L76, core-libs/styles/scss/_versioning.scss:L228-L231.
11. `forFeature` **senza** `useFeatureStyles` **non fa nulla.** Anche con il flag attivo, la classe `cxFeat_<flag>` compare solo se un componente vivo ha registrato l'uso; e per i selettori su `:root` serve la gestione manuale come in `StorefrontComponent` — core-libs/styles/scss/_features.scss:L18-L21, core-libs/storefront/layout/main/storefront.component.ts:L141-L147. `unregisterUsage` con contatore già a 0 in dev mode produce solo un warning — core-libs/core/src/features-config/services/feature-styles.service.ts:L103-L109.
12. **La classe tema sta su** `app-root`**, non su** `cx-storefront`**.** La regola `%cx-storefront { &.cx-theme-high-contrast-* { … } }` scatta solo se la classe è su `cx-storefront` stesso, mentre `ThemeService` la mette sul root component. DA VERIFICARE: non trovato altro `addClass` della classe tema in `core-libs/storefront`; potrebbe essere efficace solo nelle app che bootstrappano direttamente `cx-storefront` — core-libs/styles/scss/components/layout/_storefront.scss:L52-L59, core-libs/storefront/layout/theme/theme.service.ts:L52-L61.
13. **Dettagli di** `ThemeService`**.** `setTheme('')`/`undefined` rimuove la classe precedente ma non azzera `existingTheme` (alla chiamata successiva prova di nuovo a rimuoverla, innocuo); `setTheme` usa `rootComponent` senza guard, quindi va in errore se chiamato prima di `init`; il costruttore inietta `SiteContextConfig` senza usarlo e il commento in `init` descrive una vecchia logica — core-libs/storefront/layout/theme/theme.service.ts:L25-L61.
14. **Direzione: match esatto e rimozione di** `dir`**.** Il confronto è `includes(isocode)`: `ar_SA` non corrisponde ad `ar` — core-libs/storefront/layout/direction/direction.service.ts:L105-L108. Con lingua non mappata e senza `default`, `getDirection` restituisce `undefined` e l'attributo `dir` viene rimosso — core-libs/storefront/layout/direction/direction.service.ts:L89-L112. Una seconda chiamata a `initialize()` aggiorna `this.config` ma non riavvia la subscription (guardia `startsDetecting`) — core-libs/storefront/layout/direction/direction.service.ts:L46-L83.
15. **Direzione Sass statica.** `$direction` è `ltr` a compile time e indipendente da `DirectionService`; anche `--cx-direction` non è letta da nessuna regola — core-libs/styles/scss/cxbase/_variables.scss:L32-L32,

core-libs/styles/scss/root.scss:L16-L16. Altre variabili mai lette: `$featureMessagingItems` e le variabili header/footer di Lambda — core-libs/styles/scss/_features.scss:L1-L1, core-libs/styles/scss/theme/lambda/_variables.scss:L46-L49.

16. **Breakpoint sfalsati.** In TS `md: 992` è il massimo di md; in Bootstrap `media-breakpoint-up(md)` parte da 768px. Confondere le due semantiche sposta di uno step — core-libs/storefront/layout/config/default-layout.config.ts:L10-L18, core-libs/styles/vendor/bootstrap/scss/_variables.scss:L207-L213.
17. **SSR.** `ThemeService` e `FeatureStylesService` aggiungono classi via `Renderer2` sul root component; `DirectionService` usa `WindowRef.document`. DA VERIFICARE che classi e `dir` compaiano nell'HTML generato dal server prima dell'idratazione (non verificato sul codice di rendering) — core-libs/storefront/layout/theme/theme.service.ts:L35-L46, core-libs/core/src/features-config/services/feature-styles.service.ts:L130-L136, core-libs/storefront/layout/direction/direction.service.ts:L54-L57. Vedi 07 — SSR, hydration e TransferState e 39 — SSR ottimizzato.

---

10. Come fare debug

- **Il CSS di un componente non c'è.** Ispezionare il CSS compilato (DevTools → Sources sul bundle `styles`): cercare il selettore `cx-xyz`. Se manca, verificare che sia nell'allowlist della sua area e non in `$skipComponentStyles` — core-libs/styles/scss/_components.scss:L37-L44. Se il componente appartiene a una feature lib, cercarlo nel bundle della lib (es. `cart`), non in `styles` — projects/storefrontapp/project.json:L43-L54.
- **Un page template non ha layout.** Controllare la classe su `cx-page-layout` nel DOM e confrontarla con `$page-template-allowlist` — core-libs/styles/scss/_page-template.scss:L13-L19 (caso tipico: `SearchResultsGridPageTemplate`, §9 punto 3).
- **Colori sbagliati.** In DevTools selezionare `<app-root>` (o il root component) e guardare il pannello "Computed" per `--cx-color-primary`: si vede quale regola vince fra `:root` (`root.scss`), la classe tema (`.santorini`, `.cx-theme-high-contrast-*`) e gli override `cxFeat_*` con `!important` — core-libs/styles/scss/root.scss:L3-L70, projects/storefrontapp/src/cms-themes.scss:L1-L60.
- **Quale tema è attivo.** Leggere la classe sul root component; in parallelo controllare lo stato NgRx del site theme (Redux DevTools, selettore `getActiveSiteTheme`) — core-libs/core/src/site-theme/facade/site-theme.service.ts:L99-L104. Se la classe manca, verificare che `ThemeModule` sia caricato tramite `BaseStorefrontModule` → `LayoutModule` — core-libs/storefront/layout/layout.module.ts:L15-L25.
- **Stili `forFeature` che non si attivano.** Verificare (1) il flag nei feature toggle, (2) la presenza di `cxFeat_<flag>` sul root component, (3) che il componente chiami `useFeatureStyles('<flag>')` nel costruttore. Un breakpoint in `FeatureStylesService.registerUsage/addClass` mostra se `rootElement` è già impostato — core-libs/core/src/features-config/services/feature-styles.service.ts:L89-L136. In dev mode il warning "Feature flag CSS: ... is already not used" segnala unregister sbilanciati — core-libs/core/src/features-config/services/feature-styles.service.ts:L105-L109.
- **Direzione.** Ispezionare `document.documentElement.getAttribute('dir')`; se manca, controllare `direction.default` e il codice lingua esatto restituito da `LanguageService.getActive()` (match esatto) — core-libs/storefront/layout/direction/direction.service.ts:L104-L112.
- **Ordine e override di variabili Sass.** Inserire temporaneamente `@debug $theme-colors;` o `@debug $useTabsOnPDP;` subito dopo `@import '@spartacus/styles/scss/core'` nel foglio dell'app per vedere il valore effettivo durante la build (tecnica generica di Sass, non specifica di Spartacus). I test `sass-true` (`npm run test` in `core-libs/styles`) sono un buon modello per isolare il comportamento di un mixin — core-libs/styles/project.json:L2-L14, core-libs/styles/test/features.spec.scss:L1-L30.

11. Domande di autoverifica

1. **Perché** `@spartacus/styles` **non viene compilato in fase di build della libreria?** Perché è distribuito come sorgente Sass (nessun target di build, copia tale e quale in release): la compilazione avviene nell'app consumer, che può così impostare le variabili `!default` prima dell'import. — core-libs/styles/project.json:L2-L14, ci-scripts/release-packer.sh:L42-L43.
2. **Come fa un elemento** `cx-banner` **a ricevere i suoi stili?** Lo stile è nel placeholder `%cx-banner`; `cx-banner` è nella `$content-components-allowlist`, che confluisce in `$selectors`; il ciclo di `_components.scss` emette `cx-banner { @extend %cx-banner !optional; }`. — core-libs/styles/scss/components/content/_index.scss:L10-L14, core-libs/styles/scss/_components.scss:L21-L44.
3. **A cosa servono i placeholder** `%<selettore>__body`**?** A permettere a un componente di applicare regole a livello di `body`, che estende `%<selettore>__body` per ogni selettore in allowlist; nel core l'unico è `%cx-searchbox__body`, legato alla classe `searchbox-is-active`. — core-libs/styles/scss/_components.scss:L46-L53, core-libs/styles/scss/components/product/search/_searchbox.scss:L3-L21.
4. **Perché, pur dichiarando** `$useTabsOnPDP: false !default` **nel componente, i tab del PDP sono attivi di default?** Perché il tema santorini, valutato prima, assegna `$useTabsOnPDP: true !default`; la successiva assegnazione `!default` del componente non ha effetto. — core-libs/styles/scss/theme/santorini/_variables.scss:L169-L174, core-libs/styles/scss/components/content/tab-paragraph-container/_tab-paragraph-container.scss:L1-L2.
5. **Cosa succede se uso** `@include forFeature('myFlag')` **ma non chiamo** `useFeatureStyles('myFlag')`**?** La classe `cxFeat_myFlag` non viene aggiunta al root element (il contatore resta a 0), quindi gli stili non si attivano anche con il flag abilitato. — core-libs/styles/scss/_features.scss:L16-L31, core-libs/core/src/features-config/services/feature-styles.service.ts:L89-L95.
6. **Su quale elemento finisce la classe del site theme e chi la mette?** Sul root component bootstrappato (nell'app demo `app-root`), aggiunta da `ThemeService.setTheme`, avviato da `ThemeModule` come `APP_BOOTSTRAP_LISTENER`. — core-libs/storefront/layout/theme/theme.module.ts:L10-L25, core-libs/storefront/layout/theme/theme.service.ts:L52-L61, projects/storefrontapp/src/app/app.component.ts:L15-L15.
7. **Perché in** `root.scss` **gli override** `a11yFocusIndicatorContrast` **usano** `!important` **e** `:not(.cx-theme-high-contrast-*)`**?** `!important` serve a battere le classi tema CMS (es. `.santorini`) che stanno sullo stesso elemento con pari specificità e sono caricate dopo; le guardie `:not` evitano di toccare i temi high-contrast, che hanno colori di focus propri. — core-libs/styles/scss/root.scss:L47-L64.
8. **Con la config di default, che** `dir` **ottiene** `<html>` **per la lingua** `ar_SA`**?** `ltr`: `rtlLanguages` è `['he','ar']` e il confronto è esatto, quindi `ar_SA` non corrisponde e si ricade su `default: LTR`. — core-libs/storefront/layout/direction/config/default-direction.config.ts:L10-L19, core-libs/storefront/layout/direction/direction.service.ts:L104-L112.
9. **Perché le variabili Sass impostate solo in** `styles.scss` **non influenzano il bundle CSS di** `@spartacus/cart`**?** Perché ogni feature lib ha un bundle separato, compilato a partire dall'entry della lib che reimporta `scss/core` e, in 21 bundle su 24, da `styles-config`: è una compilazione indipendente. — projects/storefrontapp/project.json:L43-L54, projects/storefrontapp/src/styles/lib-cart.scss:L1-L2, feature-libs/cart/_index.scss:L1-L3.
10. **Il breakpoint** `md` **vale 992 in TypeScript e 768px in Bootstrap: è un bug?** No: in `BreakpointService` i numeri sono larghezze massime (md termina a 992), in Bootstrap sono minimi (md parte da 768px). I confini coincidono, la semantica è diversa. — core-libs/storefront/layout/breakpoint/breakpoint.service.ts:L161-L176, core-libs/styles/vendor/bootstrap/scss/_variables.scss:L207-L213.

---

1. A cosa serve e perché esiste

Il capitolo 07 spiega **come** Angular e Spartacus producono HTML sul server: `CommonEngine`, la catena `ngExpressEngine` → `CxCommonEngine`, i token di richiesta, TransferState e hydration. Qui ci occupiamo di **cosa succede attorno a quel render** quando il server riceve traffico reale:

- un render SSR di Spartacus può durare secondi (chiamate OCC, CMS, lazy loading) e Angular **non permette di abortirlo** (`core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L380-L388`);
- molte richieste contemporanee possono saturare CPU e memoria del processo Node;
- alcune pagine (checkout, my-account, ASM, SmartEdit) non hanno senso, o sono dannose, se renderizzate sul server;
- gli errori avvenuti dentro l'app Angular devono diventare **status HTTP corretti** (404/500) per Express e per le cache esterne;
- i log devono essere correlabili per richiesta e leggibili da strumenti di monitoring.

La risposta di Spartacus è un insieme di componenti dell'entry point `@spartacus/setup/ssr` (`core-libs/setup/ssr/public_api.ts:L7-L16`):

1. `OptimizedSsrEngine`: un wrapper attorno alla funzione view-engine Express che aggiunge timeout con **fallback CSR**, limite di **concorrenza**, **cache in memoria** dei render, **rendering strategy** per richiesta, condivisione di un render tra richieste identiche (`reuseCurrentRendering`) e protezione dai render "appesi" (`maxRenderTime`) (`core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L37-L57`, `core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L220-L237`).
2. `SsrOptimizationOptions` e i suoi default (`core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L18-L181`).
3. **Logger SSR**: `ExpressServerLogger`/`DefaultExpressServerLogger` (log JSON a riga singola in prod), `ExpressLoggerService` che collega il `LoggerService` dell'app al logger del server, contesto di richiesta con UUID e W3C `traceparent` (`core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L28-L133`, `core-libs/setup/ssr/optimized-engine/request-context.ts:L42-L51`).
4. **Error handling verso Express**: `PROPAGATE_ERROR_TO_SERVER`, `PropagatingToServerErrorHandler`, `defaultExpressErrorHandlers` (`core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32`).
5. **Express utils**: calcolo dell'origin (con `X-Forwarded-Host` fidato) e middleware di validazione dell'origin contro Host header injection e cache poisoning (`core-libs/setup/ssr/express-utils/express-request-origin.ts:L9-L26`, `core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L14-L67`).

Tutto questo è codice **solo-Node**: `optimized-ssr-engine.ts` importa `fs` ed `express` con `/* webpackIgnore: true */` (`core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L7-L9`). La gestione errori lato `@spartacus/core` (interceptor HTTP, `CxErrorHandler`, global message) è in 41 — Errori HTTP, error handling, logger e global message; qui ne vediamo solo l'aggancio al server.

projects/storefrontapp/src/server.ts	Server Express della demo: uso di riferimento di tutto quanto sopra

3. Come funziona passo per passo

3.1 Bootstrap: dal `server.ts` all'engine ottimizzato

1. La demo costruisce `ssrOptions` da variabili d'ambiente: `timeout` da `SSR_TIMEOUT` (default `defaultSsrOptimizationOptions.timeout`) e `cache` da `SSR_CACHE === 'true'` (projects/storefrontapp/src/server.ts:L22-L27).
2. `NgExpressEngineDecorator.get(engine, ssrOptions)` delega a `decorateExpressEngine` (projects/storefrontapp/src/server.ts:L29-L29, core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L43-L48). Il secondo argomento accetta `null`: con `undefined` scatta il valore di default del parametro (`defaultSsrOptimizationOptions`, quindi ottimizzazione attiva), con `null` l'ottimizzazione è di-

sattivata (core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L51-L57, core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L69-L72).

3. Quando Express registra il view engine (`server.engine('html', ngExpressEngine({ bootstrap }))`) la funzione decorata crea l'istanza di `ngExpressEngine` anteponendo `getServerRequestProviders()` ai provider di setup (core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L58-L66, projects/storefrontapp/src/server.ts:L51-L56). `ngExpressEngine` crea un unico `CxCommonEngine` (core-libs/setup/ssr/engine/ng-express-engine.ts:L82-L88), il cui costruttore legge **NG_ALLOWED_HOSTS** (deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L108-L112). I dettagli della catena sono nel cap. 07 §3.3.
4. Con opzioni truthy si istanzia `new OptimizedSsrEngine(engineInstance, optimizationOptions)` e si restituisce a Express il suo `engineInstance` (core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L69-L72), cioè `renderResponse` legato all'istanza (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L55-L57).
5. Il costruttore fonde **in modo shallow** i default con le opzioni utente, fondendo a parte `ssrFeatureToggles` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L63-L74); se dopo il merge manca `logger` lancia `'SsrOptimizationOptions.logger is not defined'`; poi crea la `RenderingCache` e logga le opzioni (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L76-L81).
6. `logOptions()` scrive "[spartacus] SSR optimization engine initialized" con le opzioni rese stampabili da `getLoggableSsrOptimizationOptions` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L84-L96), che sostituisce le istanze di classe con il nome del costruttore e le funzioni con il loro `toString()` (core-libs/setup/ssr/optimized-engine/get-loggable-ssr-optimization-options.ts:L16-L29). "Istanza di classe" significa `typeof value === 'object' && value.constructor !== Object` (core-libs/setup/ssr/optimized-engine/get-loggable-ssr-optimization-options.ts:L37-L39). Il tipo `DefaultSsrOptimizationOptions` rende obbligatorie tutte le chiavi proprio per poterle stampare tutte all'avvio (core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L201-L218).

Il resto della demo: `trust proxy = loopback` e middleware di validazione dell'origin **prima** dell'engine (projects/storefrontapp/src/server.ts:L39-L49), statici con `maxAge: '1y'` per i path con estensione, tutte le altre rotte renderizzate con `res.render(indexHtml, { req, providers: [APP_BASE_HREF] })` (projects/storefrontapp/src/server.ts:L61-L75), e infine `defaultExpressErrorHandlers(indexHtmlContent)` come ultimo middleware (projects/storefrontapp/src/server.ts:L77-L77). `indexHtml` è `index.server.html` nella cartella server di `dist` (projects/storefrontapp/src/server.ts:L34-L37): lo stesso file è il template del render **e** il documento del fallback CSR.

3.2 `renderResponse`: la pipeline di ogni richiesta

`renderResponse(filePath, options, callback)` produce uno di tre esiti: fallback CSR con `index.html`, render dell'engine Angular, risultato dalla cache in memoria (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L232-L239).

1. **Contesto di log.** `preprocessRequestForLogger(options.req, this.logger)` assegna alla richiesta UUID, timestamp e trace context; poi legge `request = options.req` e `response = options.req.res` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L245-L248). Dettagli in §3.8.
2. **Cache.** `returnCachedRender` calcola la chiave e, se `renderingCache.isReady(key)`, chiama `callback(cached.err, cached.html)`; con `cache` disabilitata cancella subito l'entry (consumo singolo). Se ha risposto, `renderResponse` logga "Render from cache" e termina (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L212-L230, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L250-L255).
3. **Si deve renderizzare?** Se `shouldRender(request)` è falso si risponde con `fallbackToCsr` e si termina (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L256-L259). Nessun render parte in

background: lo spec lo verifica per `ALWAYS_CSR` anche con `cache: true` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.spec.ts:L731-L749).

4. **Timeout o CSR immediato.**
   - Se `shouldTimeout(request)` è vero, si arma un `setTimeout` di `getTimeout(request)` ms che, a scadenza, azzera `requestTimeout`, invia il fallback CSR e logga "SSR rendering exceeded timeout ..." (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L261-L272).
   - Altrimenti si risponde **subito** con il CSR ma **senza** `return`: il render prosegue in background per riempire la cache (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L273-L279).
5. **Callback del render.** Si costruisce `renderCallback(err, html)` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L281-L300):
   - se `requestTimeout` è ancora attivo (il client attende): `clearTimeout`, `callback(err, html)` al client, log del risultato, poi `store` solo con `cache: true`, altrimenti `clear` della chiave;
   - se la richiesta ha già ricevuto il CSR: `store` **sempre**, "for future use".
6. **Delega.** `handleRender({ filePath, options, renderCallback, request })` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L302-L307), che a sua volta usa `startRender` (§3.5, §3.6).

Il fallback CSR imposta `Cache-Control: no-store` (così le cache esterne non riusano la pagina CSR) e invia il documento letto da `filePath` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L98-L110). `getDocument` legge il file con `fs.readFileSync` solo la prima volta e lo memorizza in `templateCache` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L310-L320).

3.3 Le decisioni: chiave, strategia, concorrenza, timeout

- **Chiave di rendering.** `getRenderingKey` usa `renderKeyResolver` se presente, altrimenti `getDefaultRenderKey` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L112-L116). `getDefaultRenderKey` è un alias di `getRequestUrl` (core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L196-L199), cioè `getRequestOrigin(req) + req.originalUrl` (core-libs/setup/ssr/express-utils/express-request-url.ts:L10-L12): **include host e query string**.
- **Strategia.** `getRenderingStrategy` usa `renderingStrategyResolver` se presente, altrimenti `RenderingStrategy.DEFAULT` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L118-L122). L'enum è numerico: `ALWAYS_CSR = -1`, `DEFAULT = 0`, `ALWAYS_SSR = 1` (core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L183-L187).
- `shouldRender`. Calcola `fallBack` (render già in corso per la chiave **e** `reuseCurrentRendering` disattivo) e `concurrencyLimitExceeded`, logga la causa (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L133-L151), e restituisce: render se nessun impedimento e strategia ≠ `ALWAYS_CSR`, **oppure sempre** se la strategia è `ALWAYS_SSR` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L153-L158).
- **Concorrenza.** `isConcurrencyLimitExceeded` restituisce `false` se con `reuseCurrentRendering` esiste già un render per la chiave (la richiesta non occupa un nuovo slot); altrimenti confronta `currentConcurrency >= concurrency`, e con `concurrency` falsy non c'è limite (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L166-L180).
- **Timeout.** `shouldTimeout` è vero se `timeout` è non zero **o** la strategia è `ALWAYS_SSR` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L187-L192); `getTimeout` restituisce `forcedSsrTimeout ?? 60000` per `ALWAYS_SSR`, altrimenti `timeout ?? 0` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L200-L204).

Con `timeout: 0` si ottiene quindi "CSR sempre, SSR per la prossima": lo spec verifica che la prima risposta sia il CSR, che il render resti in corso (`currentConcurrency: 1`) e che la seconda richiesta allo stesso URL riceva l'HTML (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.spec.ts:L292-L316).

3.4 Rendering strategy resolver di default

`defaultRenderingStrategyResolver(options)` è una factory che restituisce `(request) => RenderingStrategy` (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L62-L72):

1. se l'URL contiene una voce della lista fissa interna `defaultAlwaysCsrOptions.excludedUrls = ['cx-preview']` → `ALWAYS_CSR` (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L11-L13, core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L65-L67);
2. altrimenti, se `shouldFallbackToCsr` (parametri query o URL esclusi) → `ALWAYS_CSR`, altrimenti `DEFAULT` (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L41-L49, core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L69-L71).

Non restituisce mai `ALWAYS_SSR`. `hasExcludedParams` confronta i **nomi** delle proprietà di `request.query` con `excludedParams` (match esatto) (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L15-L30); `hasExcludedUrl` usa `request.url.search(url) > -1`, quindi ogni voce è una **espressione regolare** cercata come sottostringa (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L32-L39). I default escludono gli URL `checkout`, `my-account`, `punchout`, `opf` e il parametro `asm` (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver-options.ts:L12-L16).

3.5 `handleRender` e `reuseCurrentRendering`

- Senza `reuseCurrentRendering`, `handleRender` chiama direttamente `startRender` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L340-L348).
- Con `reuseCurrentRendering` (default `true`, core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L229-L229), il `renderCallback` della richiesta viene accodato in `renderCallbacks[renderingKey]` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L350-L354). Solo se non c'è già un render in corso si chiama `startRender` con un callback che, a fine render, **rilegge la Map** (non una copia locale, perché `maxRenderTime` può averla svuotata nel frattempo), invoca tutte le callback con lo stesso `(err, html)` e cancella la voce (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L356-L372).
- In questo ramo viene sempre loggato "Request is waiting for the SSR rendering to complete", anche per la richiesta che ha avviato il render (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L374-L377).

Ogni richiesta in attesa mantiene **il proprio** timer di timeout (§3.2 passo 4): il JSDoc fa l'esempio di timeout 3 s, render 4 s, seconda richiesta arrivata dopo 2 s che quindi riceve l'SSR (core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L110-L132). `renderCallbacks` è usata solo in questa modalità (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L43-L53).

3.6 `startRender` e `maxRenderTime`

1. Arma un timer `maxRenderTime` (default 300000 ms) che, a scadenza, libera la chiave in cache, azzera il timer, decrementa `currentConcurrency`, elimina le callback in attesa (con `reuseCurrentRendering`) e logga "... This might cause memory leaks!" (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L402-L417). Il JSDoc ammette che non esiste modo di abortire il render: superato il limite, il task è considerato "hanging" e il suo esito sarà ignorato (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L380-L388).
2. Logga "Rendering started", marca la chiave come `rendering` e incrementa `currentConcurrency` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L419-L421).
3. Antepone ai `providers` del render un provider `EXPRESS_SERVER_LOGGER` con il logger dell'engine (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L423-L432). È l'**unico** provider di quel token

nel codice non-spec del repo (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L426-L429).

4. Chiama `this.expressEngine(filePath, options, cb)`, cioè la funzione di `ngExpressEngine`. Al completamento: se il timer `maxRenderTime` è già scaduto, logga "completed after the specified maxRenderTime, therefore it was ignored" ed esce; altrimenti `clearTimeout`, log "Rendering completed", `currentConcurrency--`, `renderCallback(err, html)` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L434-L451).

`ngExpressEngine` calcola l'URL da `req.protocol`, header `host`, `req.baseUrl`, `req.url`, aggiunge `REQUEST`/`RESPONSE` e chiama `CxCommonEngine.render`; il risultato arriva come `callback(null, html)` o `.catch(callback)`, e gli errori sincroni sono passati solo se `instanceof Error` (core-libs/setup/ssr/engine/ng-express-engine.ts:L101-L126). Tutti i provider del render (compreso `EXPRESS_SERVER_LOGGER`) finiscono nel platform injector di `CommonEngine` (deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L185-L210; vedi cap. 07 §3.2).

`logForRenderResult` usa `log` se c'è HTML ed `error` (con `error: err` nel contesto) se c'è un errore (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L457-L474).

3.7 `RenderingCache` e dimensionamento

`RenderingCache` è una `Map<string, RenderingEntry>` con un `RenderingCacheSizeManager` creato pigramente (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L11-L23). `RenderingEntry` ha `html?`, `err?`, `time?`, `rendering?`, `_size?` (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.model.ts:L10-L20).

- `setAsRendering(key)`: prima `clear(key)` (per rilasciare la dimensione dell'entry precedente), poi il placeholder `{ rendering: true }` (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L25-L32). Gli spec verificano che sovrascrivere una chiave con `store` rilasci la dimensione precedente, altrimenti `usedSize` "drifts upward forever" (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.spec.ts:L178-L190), e che `setAsRendering` seguito da `store` non accumuli la dimensione (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.spec.ts:L192-L200).
- `isRendering(key)`: entry con `rendering` truthy (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L34-L36).
- `store(key, err, html)`: crea `{ err, html }`, aggiunge `time` solo se `ttl` è impostato, chiama `clear(key)`, e se `shouldCacheRenderingResult` restituisce falso (o manca) **non salva**; altrimenti `storeUsingMemoryLimit` (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L41-L64).
- `storeUsingMemoryLimit`: calcola la dimensione, scarta l'entry se più grande dell'intero limite, libera le entry più vecchie finché c'è spazio, salva con `_size` e traccia (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L71-L83). La liberazione rimuove la **prima chiave in ordine di inserimento** (FIFO) (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L88-L103); `get` non riordina, quindi non è LRU (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L105-L107).
- `clear(key)`: elimina e sottrae `entry?._size ?? 0` (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L109-L114).
- `isReady(key)`: entry con `html` o `err` truthy **e** fresca; `isFresh` è sempre vero senza `ttl`, altrimenti `Date.now() - time < ttl` (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L116-L127).

`RenderingCacheSizeManager` tiene `usedSize` e `CACHE_SIZE_LIMIT = options?.cacheSizeMemory ?? 0` (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L14-L29); valida le opzioni **loggando** (non lanciando) se il calculator non ha `calculateSize` o se `cacheSizeMemory` non è un numero

> 0 (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L35-L54). `hasSpaceForEntrySize(n)` è `n <= LIMIT - usedSize`, `isEntryLargerThanCacheLimit(n)` è `n > LIMIT` (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L66-L76); `trackEntrySize` satura a `Number.MAX_SAFE_INTEGER` e `untrackEntrySize` riporta a 0 i valori negativi, loggando in entrambi i casi (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L81-L109).

`DefaultCacheEntrySizeCalculator.calculateSize` usa la dimensione dell'HTML, altrimenti dell'errore, altrimenti 0 (core-libs/setup/ssr/optimized-engine/rendering-cache/default-cache-entry-size-calculator.ts:L27-L36); per gli errori somma solo `name`, `message`, `stack` e avverte della sottostima (core-libs/setup/ssr/optimized-engine/rendering-cache/default-cache-entry-size-calculator.ts:L18-L23, core-libs/setup/ssr/optimized-engine/rendering-cache/default-cache-entry-size-calculator.ts:L51-L60); le stringhe valgono `2 * str.length` byte, scelta motivata da heap snapshot che mostrano `SeqTwoByteString` (core-libs/setup/ssr/optimized-engine/rendering-cache/default-cache-entry-size-calculator.ts:L62-L74).

3.8 Contesto di richiesta e trace

- `RequestContext = { uuid, timeReceived, traceContext? }` (core-libs/setup/ssr/optimized-engine/request-context.ts:L17-L21), letto da `getRequestContext(request)` in `request.res?.locals?.cx?.request` (core-libs/setup/ssr/optimized-engine/request-context.ts:L28-L30).
- `preprocessRequestForLogger` crea il contesto con `randomUUID()` e timestamp ISO più il trace context e lo scrive in `res.locals.cx.request` (core-libs/setup/ssr/optimized-engine/request-context.ts:L42-L51, core-libs/setup/ssr/optimized-engine/request-context.ts:L75-L81); `setRequestContext` scrive solo se `request.res` esiste (core-libs/setup/ssr/optimized-engine/request-context.ts:L58-L68). Il tipo `Locals` di Express è esteso per module augmentation (core-libs/setup/ssr/optimized-engine/request-context.ts:L105-L111).
- `getTraceContext` chiama `parseTraceparent(request.get('traceparent'))`; un'eccezione viene loggata con `logger.error` e il contesto resta senza trace (core-libs/setup/ssr/optimized-engine/request-context.ts:L90-L103).
- `parseTraceparent` restituisce `undefined` se l'header non è stringa, lancia `InvalidTraceparentLengthError` se la lunghezza ≠ 55, `InvalidTraceparentFormatError` se non rispetta il pattern esadecimale, altrimenti `{ version, traceId, parentId, traceFlags }` (core-libs/setup/ssr/logger/loggers/w3c-trace-context/parse-traceparent.ts:L11-L47, core-libs/setup/ssr/logger/loggers/w3c-trace-context/w3c-trace-context.model.ts:L18-L23). I messaggi sono "Traceparent header has invalid format." e "Traceparent header has invalid length: N. Expected 55 characters." (core-libs/setup/ssr/logger/loggers/w3c-trace-context/errors/invalid-traceparent-format-error.ts:L10-L14, core-libs/setup/ssr/logger/loggers/w3c-trace-context/errors/invalid-traceparent-length-error.ts:L11-L17).

3.9 Logger SSR

Due livelli distinti:

Logger del server (`ExpressServerLogger`). Interfaccia con `log/warn/error/info/debug(message, context)`, dove `ExpressServerLoggerContext` ha `request?` e chiavi libere (core-libs/setup/ssr/logger/loggers/express-server-logger.ts:L14-L36). `DefaultExpressServerLogger` instrada ogni livello al `console.*` corrispondente (core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L28-L48). `stringifyWithContext` produce, in dev mode, un output `formatWithOptions` multi-linea; in prod un **JSON a riga singola** con le `Error` convertite da `stringifyError` (core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L63-L86). `mapContext` aggiunge `timestamp` e sostituisce `request` con `mapRequest`, che produce `{ url: request.originalUrl, ...getRequestContext(request) }` (core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L95-L122). `getLoggerInspectOptions` usa `depth: 10` e in prod `breakLength: Infinity`, per

evitare che strumenti come Kibana interpretino più righe come log diversi (core-libs/setup/ssr/logger/get-logger-inspect-options.ts:L16-L58). La modalità dipende da `isDevMode()` di Angular, vero se `ngDevMode` è `undefined` o truthy (angular:packages/core/src/util/is_dev_mode.ts:L20-L22).

Logger dell'app (`LoggerService`). `provideServer` registra `LoggerService` con `useFactory: serverLoggerServiceFactory` (core-libs/setup/ssr/providers/ssr-providers.ts:L37-L40). La factory sceglie `ExpressLoggerService` se `REQUEST` è iniettabile, altrimenti `PrerenderingLoggerService` (core-libs/setup/ssr/logger/services/server-logger-service-factory.ts:L12-L17). `ExpressLoggerService` inietta `REQUEST` ed `EXPRESS_SERVER_LOGGER`, formatta gli argomenti e passa `{ request }` come contesto (core-libs/setup/ssr/logger/services/express-logger.service.ts:L24-L61); `PrerenderingLoggerService` inoltra a `console.*` (core-libs/setup/ssr/logger/services/prerendering-logger.service.ts:L15-L39). Il ponte tra i due livelli è il provider `EXPRESS_SERVER_LOGGER` iniettato da `startRender` (§3.6).

3.10 Errori: dall'app Angular allo status HTTP

1. Sul server, `HttpErrorHandlerInterceptor` passa all'`ErrorHandler` gli errori HTTP, incapsulati in `CmsPageNotFoundOutboundHttpError` (404 su endpoint `pages`) o `OutboundHttpError` (core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L48-L98).
2. `CxErrorHandler` inoltra a tutti i `MULTI_ERROR_HANDLER` (core-libs/core/src/error-handling/cx-error-handler.ts:L18-L30); `provideServer` registra tra questi `PropagatingToServerErrorHandler` via `useExisting` (core-libs/setup/ssr/providers/ssr-providers.ts:L41-L45), che chiama `PROPAGATE_ERROR_TO_SERVER` o un no-op se assente (core-libs/setup/ssr/error-handling/multi-error-handlers/propagating-to-server-error-handler.ts:L26-L38). Il token è fornito OOTB solo da `CxCommonEngine` (core-libs/setup/ssr/error-handling/error-response/propagate-error-to-server.ts:L9-L22).
3. `CxCommonEngine.render` memorizza il **primo** errore e rigetta la promise solo a render completato (core-libs/setup/ssr/engine/cx-common-engine.ts:L41-L66).
4. `ngExpressEngine` → `.catch(callback)` → `startRender` → `renderCallback(err, undefined)` (core-libs/setup/ssr/engine/ng-express-engine.ts:L120-L123, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L450-L450).
5. Se il client attende ancora: `clearTimeout`, `callback(err)` verso Express, poi log `error`. Con `cache: true` `store` scarta l'errore per il default `shouldCacheRenderingResult` (`!err`); con `cache: false` (default) la chiave viene semplicemente cancellata con `clear` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L283-L295, core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L54-L61).
6. Express inoltra l'errore al middleware d'errore. DA VERIFICARE: è il comportamento di `res.render` senza callback in Express, i cui sorgenti non sono disponibili in `/tmp/deps`. `defaultExpressErrorHandlers` — se gli header non sono già inviati — imposta `Cache-Control: no-store` e invia il documento CSR con 404 per `CmsPageNotFoundOutboundHttpError`, 500 per ogni altro errore (core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32).

I test SSR E2E verificano proprio 404 per pagina inesistente e per errore su `cms/pages`, 500 per altri errori HTTP e per timeout del backend (projects/ssr-tests/src/ssr-testing.spec.ts:L19-L130). Il resto della catena lato `@spartacus/core` è descritto in 41.

3.11 Express utils: origin e sua validazione

`getRequestOrigin` usa `X-Forwarded-Host` (prima voce se CSV) solo se la `trust proxy fn` di Express si fida dell'indirizzo remoto, altrimenti l'header `host` (core-libs/setup/ssr/express-utils/express-request-origin.ts:L9-L26). Poiché l'origin entra nella chiave di cache (§3.3), un Host header manipolato potrebbe creare o avvelenare entry: da qui `getOriginValidationMiddleware`, che restituisce un middleware no-op se la allowlist

è vuota e altrimenti risponde `400 Bad Request` con `Cache-Control: no-store` quando l'origin non è ammesso (core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L51-L67). La allowlist accetta array o CSV (tipicamente `SSR_ALLOWED_ORIGINS`), origin completi senza slash finale, confronto case-insensitive, e `*` che copre **esattamente un'etichetta** e mai l'apex (core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L14-L50, core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L69-L99).

A un livello diverso opera `allowedHosts` di `CommonEngine` (variabile **NG_ALLOWED_HOSTS** con precedenza sull'opzione): se l'hostname non è ammesso e nessuna lista è configurata, `CommonEngine.render` logga un errore e **restituisce il documento non renderizzato come successo**; se una lista è configurata, lancia (deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L108-L135). Gli script `serve:ssr*` impostano `NG_ALLOWED_HOSTS=localhost` (package.json:L152-L155).

---

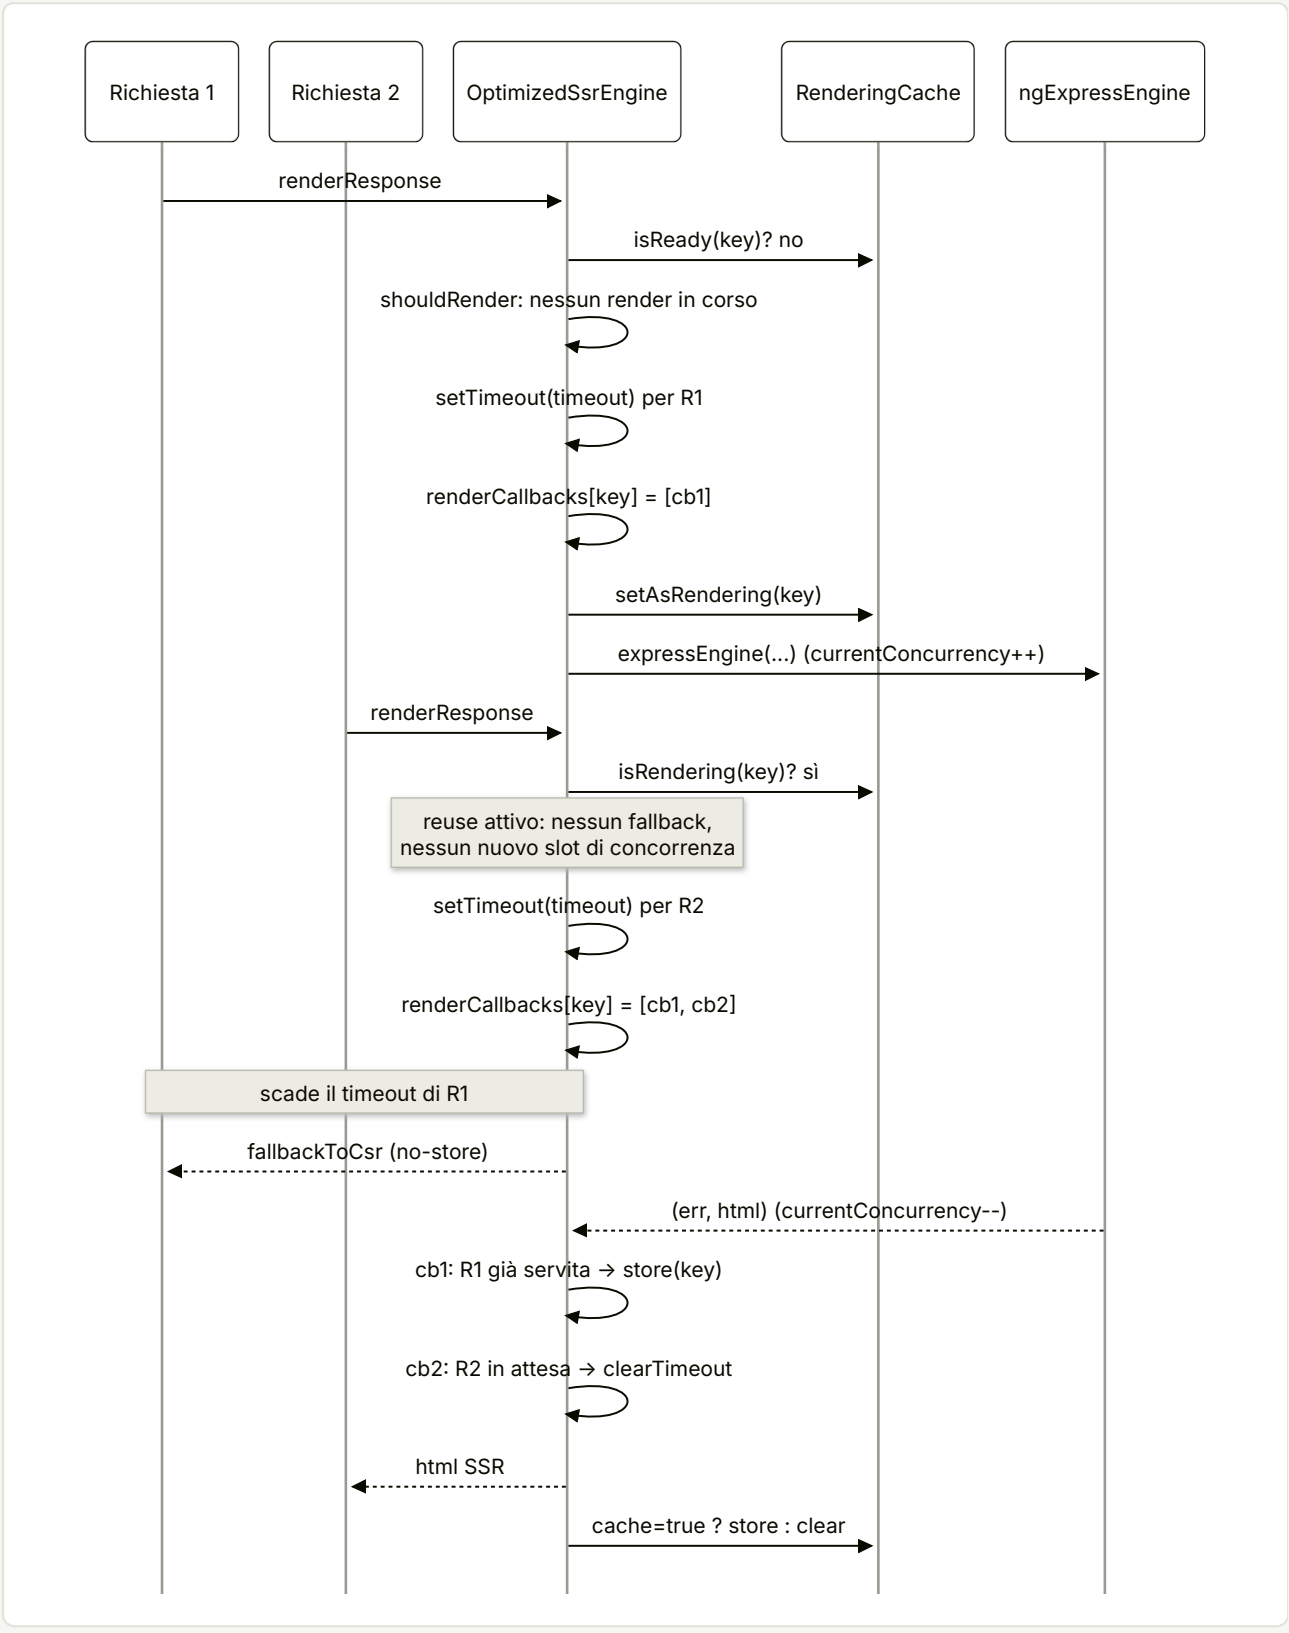
4. Diagrammi

4.1 Decisioni di `renderResponse`

■ **TAVOLA 39.1** diagramma a tutta pagina, in fondo al capitolo

Ogni nodo corrisponde a §3.2–§3.6: cache (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L212-L230), `shouldRender` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L133-L158), timeout (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L261-L279), callback (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L281-L300), reuse (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L340-L372), `startRender` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L400-L451).

4.2 `reuseCurrentRendering` con timeout (due richieste, stessa chiave)



Fondamento: `core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L137-L139`, `core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L170-L175`, `core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L261-L272`, `core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.`

ts:L282-L300, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L350-L372. Si noti l'ultimo passo: con `cache: false`, la `clear` di cb2 cancella l'entry appena salvata da cb1 (vedi §9, trappola 13).

4.3 Errore applicativo → risposta HTTP

5. Estratti di codice reale

5.1 Merge delle opzioni e logger obbligatorio

core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L59-L82

```ts
constructor(
  protected expressEngine: NgExpressEngineInstance,
  protected ssrOptions?: SsrOptimizationOptions
) {
  this.ssrOptions = ssrOptions
    ? {
        ...defaultSsrOptimizationOptions,
        // overrides the default options
        ...ssrOptions,
        // merge feature toggles
        ssrFeatureToggles: {
          ...defaultSsrOptimizationOptions.ssrFeatureToggles,
          ...ssrOptions.ssrFeatureToggles,
        },
      }
    : undefined;

  if (!this.ssrOptions?.logger) {
    throw new Error(``SsrOptimizationOptions.logger` is not defined');
  }
  this.logger = this.ssrOptions?.logger;
  this.renderingCache = new RenderingCache(this.ssrOptions);
  this.logOptions();
}
```

5.2 Il cuore di `renderResponse`

core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L250-L300

TS

```
if (this.returnCachedRender(request, callback)) {
  this.logger.log(`Render from cache (${request?.originalUrl})`, {
    request,
  });
  return;
}
if (!this.shouldRender(request)) {
  this.fallbackToCsr(response, filePath, callback);
  return;
}

let requestTimeout: ReturnType<typeof setTimeout> | undefined;
if (this.shouldTimeout(request)) {
  // establish timeout for rendering
  const timeout = this.getTimeout(request);
  requestTimeout = setTimeout(() => {
    requestTimeout = undefined;
    this.fallbackToCsr(response, filePath, callback);
    // ...
  }, timeout);
} else {
  // Here we respond with the fallback to CSR, but we don't `return`.
  // We let the actual rendering task to happen in the background

  // to eventually store the rendered result in the cache.
  this.fallbackToCsr(response, filePath, callback);
}

const renderingKey = this.getRenderingKey(request);
const renderCallback: SsrCallbackFn = (err, html): void => {
  if (requestTimeout) {
    // if request is still waiting for render, return it
    clearTimeout(requestTimeout);
    callback(err, html);

    this.logForRenderResult(err, html, request);

    // store the render only if caching is enabled
    if (this.ssrOptions?.cache) {
      this.renderingCache.store(renderingKey, err, html);
    } else {
      this.renderingCache.clear(renderingKey);
    }
  } else {
    // store the render for future use
```

```
        this.renderingCache.store(renderingKey, err, html);
      }
    };
```

5.3 shouldRender: ALWAYS_SSR scavalca tutto

core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L153-L158

```ts
    return (
      (!fallBack &&
        !concurrencyLimitExceeded &&
        this.getRenderingStrategy(request) !== RenderingStrategy.ALWAYS_CSR) ||
      this.getRenderingStrategy(request) === RenderingStrategy.ALWAYS_SSR
    );
```

5.4 Fallback CSR

core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L98-L110

```ts
  /**
   * When SSR page can not be returned in time, we're returning index.html of
   * the CSR application.
   * The CSR application is returned with the "Cache-Control: no-store" response-header. This notifies
external cache systems to not use the CSR application for the subsequent request.
   */
  protected fallbackToCsr(
    response: Response,
    filePath: string,
    callback: SsrCallbackFn
  ): void {
    response.set('Cache-Control', 'no-store');
    callback(undefined, this.getDocument(filePath));
  }
```

5.5 Condivisione del render

core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L350-L372

```ts
    const renderingKey = this.getRenderingKey(request);
    if (!this.renderCallbacks.has(renderingKey)) {
      this.renderCallbacks.set(renderingKey, []);
    }
    this.renderCallbacks.get(renderingKey)?.push(renderCallback);

    if (!this.renderingCache.isRendering(renderingKey)) {
      this.startRender({
        filePath,
```

```
        options,
        request,
        renderCallback: (err, html) => {
          // Share the result of the render with all awaiting requests for the same key:

          // Note: we access the Map at the moment of the render finished (don't store value in a local variable),
          //       because in the meantime something might have deleted the value (i.e. when `maxRenderTime` passed).
          this.renderCallbacks
            .get(renderingKey)
            ?.forEach((cb) => cb(err, html)); // pass the shared result to all waiting rendering callbacks
          this.renderCallbacks.delete(renderingKey);
        },
      });
    }
```

5.6 `maxRenderTime` e iniezione del logger

core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L405-L432

TS

```
    let maxRenderTimeout: ReturnType<typeof setTimeout> | undefined =
      setTimeout(() => {
        this.renderingCache.clear(renderingKey);
        maxRenderTimeout = undefined;
        this.currentConcurrency--;
        if (this.ssrOptions?.reuseCurrentRendering) {
          this.renderCallbacks.delete(renderingKey);
        }
        this.logger.log(
          `Rendering of ${request?.originalUrl} was not able to complete. This might cause memory leaks!`,
          { request }
        );
      }, this.ssrOptions?.maxRenderTime ?? 300000); // 300000ms == 5 minutes

    this.logger.log(`Rendering started (${request?.originalUrl})`, { request });
    this.renderingCache.setAsRendering(renderingKey);
    this.currentConcurrency++;

    options = {
      ...options,
      providers: [
        {
          provide: EXPRESS_SERVER_LOGGER,
          useValue: this.logger,
        },
```

```
        ...(options?.providers ?? []),
      ],
    };
```

5.7 Default delle opzioni

core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L220-L237

```ts
export const defaultSsrOptimizationOptions: DefaultSsrOptimizationOptions = {
  cache: false,
  cacheSizeMemory: 800_000_000,
  cacheEntrySizeCalculator: new DefaultCacheEntrySizeCalculator(),
  ttl: undefined,
  concurrency: 10,
  timeout: 3_000,
  forcedSsrTimeout: 60_000,
  maxRenderTime: 300_000,
  reuseCurrentRendering: true,
  renderingStrategyResolver: defaultRenderingStrategyResolver(
    defaultRenderingStrategyResolverOptions
  ),
  logger: new DefaultExpressServerLogger(),
  shouldCacheRenderingResult: ({ entry: { err } }) => !err,
  renderKeyResolver: getDefaultRenderKey,
  ssrFeatureToggles: {},
};
```

5.8 Resolver di strategia

core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L32-L39 e core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L62-L72

```ts
const hasExcludedUrl = (
  request: Request,
  excludedUrls: string[] | undefined
) => {
  return request.url && excludedUrls
    ? excludedUrls.some((url) => request.url.search(url) > -1)
    : false;
};
// ...
export const defaultRenderingStrategyResolver =
  (options: RenderingStrategyResolverOptions) =>
  (request: Request): RenderingStrategy => {
    if (hasExcludedUrl(request, defaultAlwaysCsrOptions.excludedUrls)) {
      return RenderingStrategy.ALWAYS_CSR;
    }
```

```
    return shouldFallbackToCsr(request, options)
      ? RenderingStrategy.ALWAYS_CSR
      : RenderingStrategy.DEFAULT;
  };
```

5.9 Eviction FIFO

core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L88-L103

```ts
  private clearOldestEntriesForSize(requiredSize: number): void {
    while (
      !this.sizeManager.hasSpaceForEntrySize(requiredSize) &&
      this.renders.size > 0
    ) {
      const oldestKey = this.renders.keys().next().value;
      if (oldestKey === undefined) {
        // Still not enough space, but no more entries to clear.
        // In practice this case should never happen, because initially we checked
`isEntryLargerThanCacheLimit` -
        // we validated whether the new entry's size is not bigger than the total cache size limit.
        break;
      }

      this.clear(oldestKey);
    }
  }
```

5.10 Log JSON in prod

core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L63-L86

```ts
  protected stringifyWithContext(
    message: string,
    context: ExpressServerLoggerContext
  ): string {
    const logObject = { message, context: this.mapContext(context) };

    if (isDevMode()) {
      // In dev mode, we want a *human-readable* string representation of the log object
      // that can be printed in the console.
      return formatWithOptions(getLoggerInspectOptions(), logObject);
    }

    // In prod mode, we want a *single-line* JSON which is machine-readable - easy to parse for
monitoring tools.
    // The monitoring tools can then decide how to display in their UI the JSON's properties.
```

```
    return JSON.stringify(
      logObject,
      /**
       * Replaces Error instances with their stringified representation.
       */
      (_key: string, value: any) => {
        return value instanceof Error ? this.stringifyError(value) : value;
      }
    );
  }
```

5.11 Scelta del `LoggerService` lato server

core-libs/setup/ssr/logger/services/server-logger-service-factory.ts:L12-L17

```ts
export const serverLoggerServiceFactory = () => {
  const isExpress = inject(REQUEST, { optional: true }) !== null;
  return isExpress
    ? inject(ExpressLoggerService)
    : inject(PrerenderingLoggerService);
};
```

5.12 Middleware d'errore Express

core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32

```ts
export const defaultExpressErrorHandlers =
  (documentContent: string): ErrorRequestHandler =>
  (err, _req, res, _next) => {
    if (!res.headersSent) {
      res.set('Cache-Control', 'no-store');
      const statusCode =
        err instanceof CmsPageNotFoundOutboundHttpError
          ? HttpResponseStatus.NOT_FOUND
          : HttpResponseStatus.INTERNAL_SERVER_ERROR;
      res.status(statusCode).send(documentContent);
    }
  };
```

5.13 Validazione dell'origin

core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L51-L67

```ts
export function getOriginValidationMiddleware(
  options: OriginValidationOptions
): RequestHandler {
  const allowedOrigins = parseAllowedOrigins(options.allowedOrigins);
```

```
  if (!allowedOrigins.length) {
    return (_req, _res, next) => next();
  }
  return (req, res, next) => {
    const origin = getRequestOrigin(req);
    if (!isAllowedOrigin(origin, allowedOrigins)) {
      res.setHeader('Cache-Control', 'no-store');
      res.status(400).send('Bad Request');
      return;
    }
    next();
  };
}
```

5.14 Configurazione della demo

projects/storefrontapp/src/server.ts:L22-L29

```ts
const ssrOptions: SsrOptimizationOptions = {
  timeout: Number(
    process.env['SSR_TIMEOUT'] ?? defaultSsrOptimizationOptions.timeout
  ),
  cache: process.env['SSR_CACHE'] === 'true',
};

const ngExpressEngine = NgExpressEngineDecorator.get(engine, ssrOptions);
```

env `SERVER_REQUEST_ORIGIN` (demo)	stringa	—	`projects/storefrontapp/src/app/app.module.server.ts:L12-L14`	`core-libs/setup/ssr/providers/server-request-origin.ts:L22-L24` (vedi cap. 07)

Nella pipeline npm: gli script `serve:ssr*` impostano `NG_ALLOWED_HOSTS=localhost`; `serve:ssr:ci` usa `SSR_TIMEOUT=0`, i `:dev`/`:watch` `SSR_TIMEOUT=30000` (package.json:L152-L155). I test SSR E2E avviano il server con `SSR_CACHE` e `SSR_TIMEOUT` (default 20000) tramite `npm run serve:ssr` (projects/ssr-tests/src/utils/ssr.utils.ts:L17-L17, projects/ssr-tests/src/utils/ssr.utils.ts:L47-L56).

---

7. Commenti e note notevoli dal sorgente

- "If the `cache` is set to `false`, the response is evicted as soon as the first successful response is successfully returned." — core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L33-L36. Descrive il consumo singolo dell'entry (§3.2 passo 2).
- Il CSR è restituito con "Cache-Control: no-store" per impedire alle cache esterne di riusarlo — core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L98-L102.
- "Here we respond with the fallback to CSR, but we don't `return`." — core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L274-L277.
- Accesso alla Map al momento del completamento "because in the meantime something might have deleted the value (i.e. when `maxRenderTime` passed)" — core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L364-L365.
- "There is no way to abort the running render of Angular Universal ... (note: it's a potential memory leak!)" — core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L383-L387.
- **IMPORTANT**: il server deve avere molta più memoria di `cacheSizeMemory`, perché serve anche al rendering — core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L41-L45.
- `maxRenderTime` "should always be higher than `timeout` and `forcedSsrTimeout`" — core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L104-L104.
- `debug` è `@deprecated` dalla 2211.27: ora tutto viene loggato incondizionatamente — core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L134-L143.
- `ssrFeatureToggles` "are temporary and will be removed in the future" e sono distinti dai feature toggle dell'app — core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L173-L178.
- **CAUTION** sulla stima della dimensione degli errori: "It's not recommended to cache error objects." — core-libs/setup/ssr/optimized-engine/rendering-cache/default-cache-entry-size-calculator.ts:L20-L22.
- 2 byte per carattere "verified through heap snapshots and memory measurements" — core-libs/setup/ssr/optimized-engine/rendering-cache/default-cache-entry-size-calculator.ts:L66-L70.
- "This should never happen. MAX_SAFE_INTEGER is 7.9 Petabytes" — core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L84-L85.
- Il ramo `oldestKey === undefined` "should never happen" — core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L94-L98.
- Commento lungo in `setAsRendering`/`store` sul perché passare da `clear()` e non da `renders.delete()` (per non "orfanare" `_size`) — core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L26-L29, core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L47-L51.
- `PROPAGATE_ERROR_TO_SERVER`: "We need it until Angular implements a proper propagation of async errors" — core-libs/setup/ssr/error-handling/error-response/propagate-error-to-server.ts:L16-L18.
- `breakLength: Infinity` per evitare che Kibana interpreti righe separate come log diversi — core-libs/setup/ssr/logger/get-logger-inspect-options.ts:L34-L40.

- "X-Forwarded-Host is normally only ever a single value, but this is to be safe." — core-libs/setup/ssr/express-utils/express-request-origin.ts:L16-L17.
- `TestConfigServerModule`: "CAUTION: DON'T USE IT IN PRODUCTION! IT HASN'T BEEN REVIEWED FOR SECURITY ISSUES." — core-libs/setup/ssr/testing/test-config-server.module.ts:L34-L34; nella demo "DO NOT USE IN CUSTOMERS APPS" — projects/storefrontapp/src/app/app.config.server.ts:L23-L26. Il modulo legge un cookie dalla `REQUEST` e lo parsa come JSON per fornire `TEST_CONFIG` (core-libs/setup/ssr/testing/test-config-server.module.ts:L11-L58), e `testing/index.ts` esporta solo il modulo (core-libs/setup/ssr/testing/index.ts:L7-L10).

8. Extension point

EXTENSION POINT	COME	DEFINITO	EXPORT
Attivare/disattivare l'ottimizzazione	`NgExpressEngineDecorator.get(engine, options);` `null` la disattiva	core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L36-L57	core-libs/setup/ssr/public_api.ts:L7-L7
Tarare timeout, cache, concorrenza, TTL, limiti	chiavi di `SsrOptimizationOptions` (§6)	core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L18-L181	core-libs/setup/ssr/optimized-engine/index.ts:L12-L12
Chiave di cache custom (es. ignorare parametri di tracking)	`renderKeyResolver: (req) => string`	core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L70-L76	idem
Strategia per richiesta (forzare SSR/CSR)	`renderingStrategyResolver`, eventualmente componendo `defaultRenderingStrategyResolver` con opzioni proprie	core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L62-L72, core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver-options.ts:L12-L16	core-libs/setup/ssr/optimized-engine/index.ts:L9-L10
Cosa mettere in cache	`shouldCacheRenderingResult({ options, entry })`	core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L158-L170	core-libs/setup/ssr/optimized-engine/index.ts:L12-L12
Stima della dimensione	`cacheEntrySizeCalculator` (implementare `CacheEntrySizeCalculator` o estendere `DefaultCacheEntrySizeCalculator`, metodi `protected` `calculateHtmlSize`, `calculateErrorSize`, `getStringSize`)	core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.model.ts:L26-L28, core-libs/setup/ssr/optimized-engine/rendering-cache/default-cache-entry-size-calculator.ts:L24-L75	core-libs/setup/ssr/optimized-engine/rendering-cache/index.ts:L7-L10
Logger del server	`logger`: implementare `ExpressServerLogger` o estendere `DefaultExpressServerLogger` (metodi `protected` `stringifyWithContext`, `mapContext`, `mapRequest`, `stringifyError`)	core-libs/setup/ssr/logger/loggers/express-server-logger.ts:L14-L48, core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L28-L133	core-libs/setup/ssr/logger/loggers/index.ts:L7-L8

EXTENSION POINT	COME	DEFINITO	EXPORT
Formattazione dei messaggi dell'app	estendere `ExpressLoggerService` (`protected formatLogMessage`)	core-libs/setup/ssr/logger/services/express-logger.service.ts:L55-L61	core-libs/setup/ssr/logger/services/index.ts:L7-L9
Leggere il contesto di richiesta (uuid, trace)	`getRequestContext(request)`	core-libs/setup/ssr/optimized-engine/request-context.ts:L28-L30	core-libs/setup/ssr/optimized-engine/index.ts:L11-L11
Comportamento dell'engine	sottoclasse di `OptimizedSsrEngine` sovrascrivendo i metodi `protected` (`fallbackToCsr`, `getRenderingKey`, `getRenderingStrategy`, `shouldRender`, `shouldTimeout`, `getTimeout`, `returnCachedRender`, `renderResponse`, `getDocument`, `logOptions`); `handleRender`, `startRender`, `isConcurrencyLimitExceeded` e `logForRenderResult` (più i campi `templateCache` e `renderCallbacks`) sono `private`	core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L84-L320, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L41-L41, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L53-L53, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L457-L457, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L166-L166, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L329-L329, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L389-L389	core-libs/setup/ssr/optimized-engine/index.ts:L7-L7
Status/documento per gli errori	sostituire o affiancare `defaultExpressErrorHandlers(document)` con un proprio `ErrorRequestHandler`	core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32	core-libs/setup/ssr/error-handling/index.ts:L8-L8
Propagare errori custom al server	`inject(PROPAGATE_ERROR_TO_SERVER, { optional: true })` o un `MULTI_ERROR_HANDLER` proprio	core-libs/setup/ssr/error-handling/error-response/propagate-error-to-server.ts:L20-L22	core-libs/setup/ssr/error-handling/index.ts:L7-L9
Allowlist di origin	`getOriginValidationMiddleware({ allowedOrigins })`	core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L10-L67	core-libs/setup/ssr/public_api.ts:L8-L8

Esempio (illustrativo, non presente nel repo; usa solo simboli esportati da `@spartacus/setup/ssr` secondo core-libs/setup/ssr/optimized-engine/index.ts:L7-L12 e core-libs/setup/ssr/public_api.ts:L7-L16): forzare l'SSR per una sezione, escludere `/cart` dall'SSR mantenendo i default, e ignorare un parametro di tracking nella chiave.

```ts
// server.ts — esempio illustrativo
import {
  NgExpressEngineDecorator,
```

```
  RenderingStrategy,
  SsrOptimizationOptions,
  defaultRenderingStrategyResolver,
  defaultRenderingStrategyResolverOptions,
  getDefaultRenderKey,
  ngExpressEngine as engine,
} from '@spartacus/setup/ssr';

const baseResolver = defaultRenderingStrategyResolver({
  ...defaultRenderingStrategyResolverOptions,
  excludedUrls: [
    ...(defaultRenderingStrategyResolverOptions.excludedUrls ?? []),
    '/cart', // NB: RegExp/sottostringa su request.url (§9)
  ],
});

const ssrOptions: SsrOptimizationOptions = {
  timeout: 3000,
  cache: true,
  ttl: 10 * 60_000,
  renderingStrategyResolver: (req) =>
    req.url.startsWith('/campaign/')
      ? RenderingStrategy.ALWAYS_SSR // ignora concurrency (§9)
      : baseResolver(req),
  renderKeyResolver: (req) => {
    // chiave di default = origin + originalUrl; rimuove i parametri utm_*
    const url = new URL(getDefaultRenderKey(req));
    [...url.searchParams.keys()]
      .filter((k) => k.startsWith('utm_'))
      .forEach((k) => url.searchParams.delete(k));
    return url.toString();
  },
};

const ngExpressEngine = NgExpressEngineDecorator.get(engine, ssrOptions);
```

Ricette pertinenti in Parte III:

- override di configurazione e provider via DI (es. registrare un `LoggerService`/`MULTI_ERROR_HANDLER` custom solo lato server): 50 — Ricette: configurazione, DI, interceptor, eventi;
- cosa è API pubblica in `@spartacus/setup/ssr` e cosa no (`decorateExpressEngine`, `getRequestOrigin`, `getRequestUrl`, `parseTraceparent`, `preprocessRequestForLogger` non sono esportati; i metodi `private` dell'engine non sono un contratto): 54 — API pubblica vs interna, upgrade, anti-pattern, checklist.

Simboli non esportati dal public_api: `decorateExpressEngine` e i tipi `NgExpressEngine`/`NgExpressEngineInstance` (core-libs/setup/ssr/engine-decorator/index.ts:L7-L7), `getLoggableSsrOptimizationOptions` e `preprocessRequestForLogger` (core-libs/setup/ssr/optimized-engine/index.ts:L7-L12), `getRequestOrigin`/`getRequestUrl` (core-libs/setup/ssr/public_api.ts:L7-L16; `getDefaultRenderKey` invece sì), `parseTraceparent`, `W3cTraceContext` e gli errori traceparent (nessun barrel riesporta `w3c-trace-context/*`: core-libs/setup/ssr/logger/loggers/index.ts:L7-L8).

9. Trappole, casi limite, comportamenti controintuitivi

1. `timeout: 0` **= CSR immediato + render in background.** Con strategia `DEFAULT` e `timeout` falsy `shouldTimeout` è falso: ogni prima richiesta riceve CSR e l'SSR serve la successiva (anche con `cache: false`, una volta). È la modalità di `serve:ssr:ci` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L187-L192, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L273-L279, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L296-L299, package.json:L154-L154).
2. `cache: false` **non significa "nessuna memoria".** I render terminati dopo il fallback sono salvati comunque (soggetti a `cacheSizeMemory` e `shouldCacheRenderingResult`) finché una richiesta non li consuma; se nessuno richiede più quell'URL restano in memoria (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L296-L299, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L223-L226, core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L24-L31).
3. `ALWAYS_SSR` **ignora concorrenza e render in corso.** Può superare `concurrency` e, senza `reuseCurrentRendering`, avviare un secondo render per la stessa chiave: lo spec lo verifica (`currentConcurrency: 2`) (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L153-L158, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.spec.ts:L681-L713). Il resolver di default non restituisce mai `ALWAYS_SSR`: serve un resolver custom (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L62-L72).
4. `excludedUrls` **sono RegExp/sottostringhe su** `request.url`**.** `'checkout'` esclude qualunque URL che contenga "checkout" (anche un prodotto con quello slug); caratteri speciali regex cambiano il significato (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L36-L38).
5. `cx-preview` **è sempre CSR** (SmartEdit), non disattivabile tramite le opzioni del resolver di default (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L11-L13, core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L65-L67).
6. **Chiave = origin +** `originalUrl`**.** Varianti di query string o host diversi creano entry distinte; Host header manipolati possono avvelenare la cache, motivo di `getOriginValidationMiddleware` (core-libs/setup/ssr/express-utils/express-request-url.ts:L10-L12, core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L14-L17).
7. **Merge shallow delle opzioni.** Passare `logger: undefined` esplicito fa lanciare il costruttore; `renderingStrategyResolver: undefined` riporta la strategia a `DEFAULT`, quindi checkout/my-account vengono renderizzati in SSR (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L63-L78, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L118-L122).
8. **Opzione** `null` **e log di avvio.** `typeof null === 'object'`, e `isClassInstance` accede a `value.constructor`: un'opzione impostata a `null` farebbe fallire il costruttore in `logOptions` con un `TypeError`. Analisi statica (core-libs/setup/ssr/optimized-engine/get-loggable-ssr-optimization-options.ts:L16-L29, core-libs/setup/ssr/optimized-engine/get-loggable-ssr-optimization-options.ts:L37-L39).
9. `get(engine)` ≠ `get(engine, null)`. Senza secondo argomento l'ottimizzazione è attiva con i default; solo `null` la disattiva (core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L51-L57, core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L69-L72).
10. **Senza** `OptimizedSsrEngine` **manca** `EXPRESS_SERVER_LOGGER`**.** L'unico provider è in `startRender`; con `null`, `ExpressLoggerService` (scelto perché `REQUEST` esiste) fa un `inject(EXPRESS_SERVER_LOGGER)` non opzionale → probabile `NullInjectorError` alla prima risoluzione di `LoggerService`. DA VERIFICARE a runtime (manca `node_modules`) (core-libs/setup/ssr/logger/services/express-logger.service.ts:L26-L27, core-libs/setup/ssr/logger/services/server-logger-service-factory.ts:L12-L17, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L426-L429).
11. `allowedHosts` **non configurato → finto SSR, potenzialmente in cache.** Senza **NG_ALLOWED_HOSTS** né `allowedHosts`, `CommonEngine.render` restituisce il documento grezzo come successo; per

`OptimizedSsrEngine` è HTML valido e, con `cache: true`, viene salvato e servito con 200 senza `no-store`. La demo non passa `allowedHosts` e conta sulla variabile negli script npm (`deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L117-L135`, `projects/storefrontapp/src/server.ts:L51-L56`, `package.json:L152-L155`). `DA VERIFICARE` il caso di URL non parsabile, per cui la validazione viene saltata (`deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L117-L117`).

12. **Origin incoerente.** `ngExpressEngine` costruisce l'URL con `req.get('host')`, mentre la chiave di cache e `SERVER_REQUEST_ORIGIN` usano `getRequestOrigin`, che può preferire `X-Forwarded-Host` (`core-libs/setup/ssr/engine/ng-express-engine.ts:L104-L106`, `core-libs/setup/ssr/express-utils/express-request-origin.ts:L12-L25`).
13. `reuseCurrentRendering` **+** `cache: false`**:** `store`**/**`clear` **multipli sulla stessa chiave.** Le callback condivise vengono eseguite in sequenza: una richiesta già servita in CSR fa `store`, una ancora in attesa fa `clear`; l'esito finale in cache dipende dall'ordine d'arrivo. Analisi statica (`core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L282-L300`, `core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L366-L368`).
14. **L'eviction FIFO può rimuovere un placeholder** `rendering`**.** `clearOldestEntriesForSize` non distingue i placeholder `{ rendering: true }` (dimensione 0): rimuoverne uno non libera spazio, ma rende falso `isRendering` per un render ancora in corso (possibile render duplicato o fallback diverso). Analisi statica; `DA VERIFICARE` con un test, non coperto dagli spec letti (`core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L25-L32`, `core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L88-L103`).
15. **Nessun LRU, TTL pigro.** `get` non riordina; le entry scadute non vengono rimosse finché non sono sovrascritte o sfrattate e continuano a occupare `usedSize` (`core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L105-L107`, `core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L116-L127`).
16. **Errori non cachati, neppure "one-shot".** Con il default `!err` un render tardivo in errore non viene conservato: la richiesta successiva rifà il render (`core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L234-L234`, `core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L54-L61`).
17. **Opzioni di cache invalide solo loggate.** `cacheSizeMemory` ≤ 0 o calculator mancante producono un log d'errore; con limite 0 nessuna entry con dimensione > 0 viene mai salvata, neppure il one-shot di §3.2 (`core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L35-L54`, `core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L66-L76`).
18. **Errori sincroni non-**`Error` **inghiottiti.** In `ngExpressEngine` un `throw` di un valore che non è `Error` non chiama il callback: il render resta "in corso" fino a `maxRenderTime` (`core-libs/setup/ssr/engine/ng-express-engine.ts:L124-L126`).
19. **Concorrenza per-processo e senza abort.** `currentConcurrency` è un contatore in memoria per istanza; dopo `maxRenderTime` lo slot è liberato ma il render continua a consumare CPU/memoria (`core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L37-L41`, `core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L405-L417`).
20. `maxRenderTime` **<** `timeout`**.** Vietato dal JSDoc: il render verrebbe dichiarato "hanging" prima del timeout e il suo esito ignorato, così il client riceve CSR solo allo scadere del proprio timeout (`core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L104-L104`, `core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L435-L442`).
21. **Log "waiting" fuorviante.** Con reuse attivo anche la richiesta che avvia il render logga "Request is waiting...", e i log "Rendering started/completed" portano il contesto della sola prima richiesta (`core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L374-L377`, `core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L419-L419`).

22. `traceparent` **malformato → un log** `error` **per richiesta**, senza bloccare il render (core-libs/setup/ssr/optimized-engine/request-context.ts:L94-L102).
23. **Template letto una sola volta.** `getDocument` usa `readFileSync` al primo accesso e poi la `templateCache`: nessuna invalidazione se il file cambia a caldo (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L311-L320).
24. `defaultExpressErrorHandlers` **non chiama** `next` **e non logga**: se gli header sono già inviati l'errore sparisce (core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L23-L31).
25. **Wildcard di origin.** `*` non copre l'apex né più livelli: `https://*.my.domain.com` non ammette `a.b.my.domain.com` (core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L32-L36, core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L89-L95).
26. **Formato dei log deciso da** `ngDevMode` **del processo.** Nel bundle server ottimizzato i log sono JSON a riga singola. DA VERIFICARE che il build server definisca `ngDevMode` falso: dipende dalla configurazione del builder, non letta (core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L69-L73, angular:packages/core/src/util/is_dev_mode.ts:L20-L22).
27. **Istanze di default condivise.** `DefaultCacheEntrySizeCalculator` e `DefaultExpressServerLogger` dei default sono create una volta al caricamento del modulo e condivise da tutti gli engine che usano i default (core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L223-L233).

---

10. Come fare debug

- **Leggere il log di avvio.** "[spartacus] SSR optimization engine initialized" elenca tutte le opzioni effettive dopo il merge, con resolver e funzioni stampati come sorgente (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L84-L96, core-libs/setup/ssr/optimized-engine/get-loggable-ssr-optimization-options.ts:L16-L29). È il primo posto dove verificare un override "perso" (§9 trappola 7).
- **Seguire una richiesta per UUID.** Ogni log del server emesso con una `request` nel contesto (tutti quelli legati a una richiesta) porta `context.request.uuid`, `timeReceived`, `url` ed eventuale `traceContext` (core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L98-L107, core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L117-L122); il log di avvio e gli errori di `RenderingCacheSizeManager` non hanno contesto di richiesta (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L93-L95, core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L40-L43, core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L49-L52, core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L87-L90, core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache-size-manager.ts:L103-L106). Messaggi tipici: "Render from cache", "CSR fallback: rendering in progress", "CSR fallback: Concurrency limit exceeded", "SSR rendering exceeded timeout", "Rendering started/completed", "Request is resolved with the SSR rendering result/error", "... This might cause memory leaks!", "... completed after the specified maxRenderTime, therefore it was ignored." (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L142-L150, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L251-L253, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L268-L271, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L413-L416, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L419-L419, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L437-L440, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L445-L447, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L462-L473).
- **Correlare con il tracing distribuito.** Inviare un header `traceparent` valido (55 caratteri) e cercare `traceId` nei log (core-libs/setup/ssr/logger/loggers/w3c-trace-context/parse-traceparent.ts:L11-L47).

- **Riconoscere un CSR.** La risposta CSR (fallback o errore) ha `Cache-Control: no-store` (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L108-L108, core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L25-L25). Una pagina "SSR" senza contenuto, con 200 e senza `no-store`, fa pensare a §9 trappola 11 (`allowedHosts`): cercare nell'output "Falling back to client side rendering" (deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L117-L135).
- **Isolare l'ottimizzazione.** Per escludere effetti di cache/timeout: `SSR_TIMEOUT` alto (gli script `:dev` usano 30000) e `SSR_CACHE` non impostato (package.json:L152-L155, projects/storefrontapp/src/server.ts:L22-L27); per vedere sempre il render "fresco", `timeout: 0` mostra CSR + SSR alla seconda richiesta (§3.3).
- **Log leggibili in locale.** In dev mode `DefaultExpressServerLogger` usa `formatWithOptions` multi-linea (core-libs/setup/ssr/logger/loggers/default-express-server-logger.ts:L69-L73).
- **Test di riferimento.** Gli scenari di `OptimizedSsrEngine` sono coperti da `core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.spec.ts` (timeout, cache, concurrency, ttl, strategie, `maxRenderTime`, reuse: core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.spec.ts:L267-L1413); gli scenari end-to-end di status HTTP da projects/ssr-tests/src/ssr-testing.spec.ts:L19-L130. Per lanciare questi ultimi usare la skill `ssr` del progetto.

---

11. Domande di autoverifica

1. **Con le opzioni di default, cosa riceve il client se il render dura 5 secondi?** Il fallback CSR allo scadere di `timeout` (3000 ms), con `Cache-Control: no-store`; il render continua e il suo HTML viene salvato per la richiesta successiva alla stessa chiave, che lo consuma una sola volta perché `cache` è `false` (core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L220-L229, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L261-L272, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L296-L299, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L223-L226).
2. **Che differenza c'è tra** `NgExpressEngineDecorator.get(engine)` **e** `NgExpressEngineDecorator.get(engine, null)`**?** Nel primo caso `optimizationOptions` è `undefined`, scatta il default `defaultSsrOptimizationOptions` e si usa `OptimizedSsrEngine`; nel secondo l'istanza di `ngExpressEngine` è restituita così com'è (core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L51-L57, core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L69-L72).
3. **Perché una seconda richiesta per lo stesso URL, durante un render in corso, non ottiene un CSR immediato con i default?** Perché `reuseCurrentRendering` è `true`: `fallBack` è falso, `isConcurrencyLimitExceeded` restituisce `false` senza occupare uno slot e la callback viene accodata al render esistente, con il proprio timeout (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L137-L139, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L170-L175, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L350-L372).
4. **Come si ottiene che una pagina venga sempre servita in SSR, anche oltre il limite di concorrenza?** Con un `renderingStrategyResolver` custom che restituisce `RenderingStrategy.ALWAYS_SSR`: `shouldRender` è sempre vero e il timeout usato è `forcedSsrTimeout` (default 60 s). Il resolver di default non lo fa mai (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L153-L158, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L200-L204, core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L62-L72).
5. **Un URL di prodotto contiene la parola** `checkout` **nello slug: che succede?** Con il resolver di default viene servito in CSR, perché `excludedUrls` è valutato con `request.url.search(url) > -1` (core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver.ts:L32-L39, core-libs/setup/ssr/optimized-engine/rendering-strategy-resolver-options.ts:L12-L16).

6. **Come arriva un 404 CMS al browser come status HTTP 404?** L'interceptor crea `CmsPageNotFoundOutboundHttpError`, `CxErrorHandler` lo passa a `PropagatingToServerErrorHandler`, che chiama `PROPAGATE_ERROR_TO_SERVER`; `CxCommonEngine` rigetta a fine render, l'errore passa da `OptimizedSsrEngine` a Express e `defaultExpressErrorHandlers` risponde 404 con il documento CSR (core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L48-L98, core-libs/setup/ssr/providers/ssr-providers.ts:L41-L45, core-libs/setup/ssr/engine/cx-common-engine.ts:L41-L66, core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32).
7. **Perché la cache può sfrattare una pagina molto visitata prima di una mai riletta?** Perché l'eviction rimuove la prima chiave in ordine di inserimento e `get` non riordina la Map: è FIFO, non LRU (core-libs/setup/ssr/optimized-engine/rendering-cache/rendering-cache.ts:L88-L107).
8. **Quanta memoria "costa" alla cache una pagina HTML di 500.000 caratteri?** 1.000.000 di byte secondo `DefaultCacheEntrySizeCalculator`, che stima 2 byte per carattere (core-libs/setup/ssr/optimized-engine/rendering-cache/default-cache-entry-size-calculator.ts:L62-L74).
9. **Da dove viene il logger che `ExpressLoggerService` usa dentro l'app Angular?** Dal provider `EXPRESS_SERVER_LOGGER` che `startRender` antepone ai provider di ogni render, con il `logger` delle opzioni (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L423-L432, core-libs/setup/ssr/logger/services/express-logger.service.ts:L24-L27).
10. **Cosa succede a un render che non termina mai?** Dopo `maxRenderTime` (default 5 minuti) la chiave viene liberata, lo slot di concorrenza restituito, le callback in attesa dimenticate e viene loggato un possibile memory leak; se il render finisce più tardi, il suo esito è ignorato. Il render non viene abortito (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L380-L388, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L405-L417, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L434-L442).

1. A cosa serve e perché esiste

Una storefront deve farsi trovare dai motori di ricerca e condividere bene sui social. Per farlo ogni pagina deve avere `<title>`, `<meta name="description">`, `<meta name="robots">`, un `<link rel="canonical">` e possibilmente dati strutturati JSON-LD. In una Single Page Application questi tag cambiano a ogni navigazione e, perché un crawler li veda, vanno scritti anche nell'HTML prodotto in SSR. Spartacus divide il problema in tre livelli, in due librerie diverse.

LIVELLO	LIBRERIA	CLASSI CHIAVE	DOMANDA A CUI RISPONDE
Raccolta dei meta (dati)	`@spartacus/core`	`PageMetaService`, `PageMetaResolver`, `BasePageMetaResolver`, `PageLinkService`	"Qual è il title, la description, il canonical… della pagina corrente?"
Scrittura nel DOM (rendering)	`@spartacus/storefront`	`SeoModule`, `SeoMetaService`, `PageMetaLinkService`	"Come trasformo un `PageMeta` in tag dentro `<head>`?"
Dati strutturati (JSON-LD)	`@spartacus/storefront`	`StructuredDataFactory`, `SCHEMA_BUILDER`, `JsonLdScriptFactory`	"Quale schema.org scrivo nello `<script type="application/ld+json">`?"

Il cuore è il modello `PageMeta`: un oggetto con le proprietà opzionali `title`, `heading`, `description`, `robots`, `image`, `breadcrumbs` e `canonicalUrl` (core-libs/core/src/cms/model/page.model.ts:L40-L78). `PageMetaService` lo calcola per la pagina CMS corrente, scegliendo tra più `PageMetaResolver` quello con lo score migliore per tipo, template e uid della pagina (core-libs/core/src/cms/page/page-meta.resolver.ts:L31-L45). Il resolver scelto espone metodi `resolve*` che restituiscono `Observable`, e una configurazione decide quale metodo alimenta quale proprietà (core-libs/core/src/cms/page/config/default-page-meta.config.ts:L9-L40).

`PageMeta` non serve solo alla SEO. Lo usano anche la UI, per l'heading `<h1>` (core-libs/storefront/cms-components/navigation/page-header/page-title.utils.ts:L11-L18) e per il breadcrumb (core-libs/storefront/cms-components/navigation/breadcrumb/breadcrumb.component.ts:L59-L63), e il builder JSON-LD del breadcrumb (core-libs/storefront/cms-structure/seo/structured-data/builders/breadcrumb/breadcrumb-schema.builder.ts:L19-L23). Per questo l'interfaccia distingue `heading` (UI) da `title` (browser e crawler) (core-libs/core/src/cms/page/page.resolvers.ts:L10-L25).

La seconda metà del capitolo riguarda la **PWA**. `PwaModule` registra il service worker di Angular (`ngsw-worker.js`), ma lo abilita solo fuori da dev mode e con `pwa.enabled` (core-libs/storefront/cms-structure/pwa/pwa.module.ts:L19-L23). Inoltre gestisce il prompt "Add to Home Screen" tramite l'evento browser `beforeinstallprompt` (core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L36-L57). Entrambe le funzioni sono disattivate per default (core-libs/storefront/cms-structure/pwa/pwa.module-config.ts:L21-L26).

`SeoModule` e `PwaModule` vengono importati da `BaseStorefrontModule` (core-libs/storefront/base-storefront.module.ts:L26-L49), mentre `PageMetaModule.forRoot()` arriva tramite `CmsModule` (core-libs/core/src/cms/cms.module.ts:L14-L16), che è importato da `BaseCoreModule` (core-libs/core/src/base-core.module.ts:L34-L34). I resolver di prodotto, categoria e ricerca si aggiungono solo con `ProductModule.forRoot()` (core-libs/core/src/product/product.module.ts:L16-L49).

Capitoli collegati: il caricamento della pagina CMS che fa partire tutto è in 15 — CMS core; il rendering SSR, dove questi tag hanno davvero valore, è in 39 — SSR ottimizzato e 07 — SSR, hydration e TransferState; il meccanismo `UnifiedInjector` per i provider multi nei moduli lazy è in 12 — Feature module e lazy loading; i resolver di prodotto sono descritti anche in 24 — Prodotto e ricerca.

3. Come funziona passo per passo

3.1 Dal backend: robots nella pagina CMS

1. La pagina CMS OCC porta un singolo `robotTag` (es. `NOINDEX_FOLLOW`). Il normalizer lo spezza in un array di due `PageRobotsMeta` e, se manca, assegna un array vuoto (core-libs/core/src/occ/adapters/cms/converters/occ-cms-page-normalizer.ts:L198-L222).
2. Title e description arrivano direttamente come `page.title` e `page.description`, e `BasePageMetaResolver` li legge dalla pagina corrente (core-libs/core/src/cms/page/base-page-meta.resolver.ts:L47-L61).

3.2 Registrazione dei resolver

1. `PageMetaModule` fa multi-provide del token `PageMetaResolver` con `useExisting: ContentPageMetaResolver`; `forRoot()` aggiunge `provideDefaultConfig(defaultPageMetaConfig)` (core-libs/core/src/cms/page/page-meta.module.ts:L13-L29).
2. `ProductModule.forRoot()` aggiunge, sullo stesso token, `ProductPageMetaResolver`, `CategoryPageMetaResolver`, `SearchPageMetaResolver` e `CouponSearchPageResolver` (core-libs/core/src/product/product.module.ts:L16-L49). Nella demo `ProductModule.forRoot()` è importato in `spartacus-features.module.ts` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L220-L220), e la schematic `add-spartacus` genera la stessa riga (core-libs/schematics/src/add-spartacus/spartacus-features.ts:L186-L186).
3. Le feature-libs aggiungono i loro resolver con lo stesso schema. Per esempio `CheckoutPageMetaResolver` usa `CONTENT_PAGE + MultiStepCheckoutSummaryPageTemplate` (feature-libs/checkout/base/core/services/checkout-page-meta.resolver.ts:L46-L47), mentre `CustomerTicketingPageMetaResolver` usa

`pageUid = 'support-ticket-details'` (feature-libs/customer-ticketing/core/services/customer-ticketing-page-meta.resolver.ts:L53-L54).

3.3 `PageMetaService`: raccolta dei resolver

1. `PageMetaService` è `providedIn: 'root'` e riceve `CmsService`, `UnifiedInjector`, `PageMetaConfig` e `PLATFORM_ID`; quest'ultimo è commentato come deprecato (core-libs/core/src/cms/facade/page-meta.service.ts:L29-L41).
2. `resolvers$ = unifiedInjector.getMulti(PageMetaResolver)` con `shareReplay({bufferSize:1, refCount:true})` (core-libs/core/src/cms/facade/page-meta.service.ts:L53-L57).
3. `getMulti` parte dall'injector root (`startWith(this.rootInjector)`) e aggiunge l'injector di ogni modulo lazy caricato (core-libs/core/src/lazy-loading/unified-injector.ts:L32-L35). Per i moduli lazy legge solo le istanze proprie (`{ self: true }`, core-libs/core/src/lazy-loading/unified-injector.ts:L52-L68) e accumula le liste con `scan`. Emette solo quando trova istanze nuove e lancia un errore se il token mescola provider multi e singoli (core-libs/core/src/lazy-loading/unified-injector.ts:L79-L93). In pratica, quando un modulo lazy che fornisce un resolver (come quello del checkout) viene caricato, `resolvers$` riemette la lista allargata.

3.4 `PageMetaService`: scelta del resolver

1. `meta$` parte da `cms.getCurrentPage()`, scarta le pagine falsy, e con `switchMap` passa a `getMetaResolver(page)` (core-libs/core/src/cms/facade/page-meta.service.ts:L59-L68).
2. `getMetaResolver` applica `resolveApplicable(resolvers, [page], [page])` a ogni emissione di `resolvers$` (core-libs/core/src/cms/facade/page-meta.service.ts:L133-L139).
3. `resolveApplicable` tiene solo le istanze con `hasMatch(page)` vero e, tra queste, sceglie quella con `getPriority` più alta. Il confronto è `lastPriority > currPriority` (stretto), quindi **a parità vince il provider registrato per ultimo** (core-libs/core/src/util/applicable.ts:L63-L87), come dichiara anche il JSDoc (core-libs/core/src/util/applicable.ts:L47-L62).
4. In `PageMetaResolver`, `hasMatch` è `getScore(page) > 0` e `getPriority` è lo score stesso (core-libs/core/src/cms/page/page-meta.resolver.ts:L47-L53). Lo score somma ±1 per `pageType`, ±1 per `pageTemplate` e ±10 per `pageUid`; ogni criterio conta solo se la proprietà è valorizzata sul resolver (core-libs/core/src/cms/page/page-meta.resolver.ts:L31-L45).

Esempi di scoring con i resolver standard (calcolati da core-libs/core/src/cms/page/page-meta.resolver.ts:L31-L45 e core-libs/core/src/product/services/coupon-search-page-meta.resolver.ts:L89-L91):

PAGINA	CONTENTPAGE… (CONTENT)	SEARCH… (CONTENT + TEMPLATE RICERCA)	COUPONSEARCH… (COME SEARCH ±1)	PRODUCT… (PRODUCT)	CATEGORY… (CATEGORY)	VINCE
contenuto generico, template qualsiasi	1	0	−1	−1	−1	Content
`SearchResultsListPageTemplate` senza couponcode	1	2	1	−1	−1	Search
`SearchResultsListPageTemplate` con couponcode	1	2	3	−1	−1	CouponSearch
PDP	−1	−2	−3	1	−1	Product
PLP / categoria	−1	−2	−3	−1	1	Category

Un resolver con `pageUid` corretto prende +10 e vince quasi sempre: per esempio `CustomerTicketingPageMetaResolver` arriva a 11 sulla pagina `support-ticket-details` (feature-libs/customer-ticketing/core/services/customer-ticketing-page-meta.resolver.ts:L51-L55). Se nessun resolver ha score > 0, `meta$` emette `null` (core-libs/core/src/cms/facade/page-meta.service.ts:L64-L66).

3.5 `PageMetaService`: composizione del `PageMeta`

1. `getResolverMethods()` trasforma `pageMeta.resolvers` (array di `{property, method}`) in una mappa `{ property: method }`; senza config restituisce `{}` (core-libs/core/src/cms/facade/page-meta.service.ts:L115-L125).
2. La config di default mappa 7 proprietà: `title→resolveTitle`, `heading→resolveHeading`, `breadcrumbs→resolveBreadcrumbs`, `description→resolveDescription`, `image→resolveImage`, `robots→resolveRobots`, `canonicalUrl→resolveCanonicalUrl` (core-libs/core/src/cms/page/config/default-page-meta.config.ts:L9-L40).
3. `resolve(metaResolver)` tiene solo i metodi che esistono **sull'istanza scelta**, li invoca senza argomenti, mappa ogni risultato in `{ [property]: data }` e unisce tutto con `uniteLatest` + `Object.assign`. Se non resta alcun metodo restituisce `of({})` (core-libs/core/src/cms/facade/page-meta.service.ts:L84-L103).
4. `uniteLatest` emette la prima combinazione in modo sincrono; le successive sono raggruppate con `audit` sull'`asapScheduler`, così più sorgenti che cambiano insieme producono un'unica emissione (core-libs/core/src/util/rxjs/unite-latest.ts:L15-L47). Sotto c'è un `combineLatest` (core-libs/core/src/util/rxjs/unite-latest.ts:L45-L45), che emette solo dopo che **tutte** le sorgenti hanno emesso almeno una volta (deps:rxjs-7.8.2/package/src/internal/observable/combineLatest.ts:L242-L269).
5. `getMeta()` restituisce `meta$`, condiviso con `shareReplay({bufferSize:1, refCount:true})` (core-libs/core/src/cms/facade/page-meta.service.ts:L67-L77).
6. Il costruttore si sottoscrive a `languageService.getActive()` con `skip(1)` e `distinctUntilChanged()`, e a ogni cambio lingua chiama `cms.refreshLatestPage()` (core-libs/core/src/cms/facade/page-meta.service.ts:L42-L50). Questo metodo prende il page context corrente e fa dispatch di `CmsActions.LoadCmsPageData` (core-libs/core/src/cms/facade/cms.service.ts:L197-L204): la pagina viene ricaricata e i meta si ricalcolano nella nuova lingua.

3.6 `BasePageMetaResolver` e `ContentPageMetaResolver`

1. `BasePageMetaResolver` (`providedIn: 'root'`) implementa title, description, breadcrumb, robots e canonical (core-libs/core/src/cms/page/base-page-meta.resolver.ts:L25-L42). **Non** estende `PageMetaResolver`: non viene mai scelto da `resolveApplicable`, serve solo come delegato.
2. `title$`, `description$` e `robots$` derivano da `page.title`, `page.description` e `page.robots || []` (core-libs/core/src/cms/page/base-page-meta.resolver.ts:L47-L61).
3. Il breadcrumb home è `[{ label: translate('common.home'), link: '/' }]` (core-libs/core/src/cms/page/base-page-meta.resolver.ts:L66-L68). `breadcrumb$` lo unisce con i breadcrumb delle route Angular figlie, prodotti da `RoutingPageMetaResolver.resolveBreadcrumbs()` (core-libs/core/src/cms/page/base-page-meta.resolver.ts:L73-L79).
4. `resolveCanonicalUrl(options?)` ricalcola `pageLinkService.getCanonicalUrl(options)` a ogni `NavigationEnd`, con `startWith(null)` per emettere subito (core-libs/core/src/cms/page/base-page-meta.resolver.ts:L101-L107).
5. `ContentPageMetaResolver` estende `PageMetaResolver`, imposta `pageType = PageType.CONTENT_PAGE` e delega i cinque metodi a `BasePageMetaResolver` (core-libs/core/src/cms/page/content-page-meta.resolver.ts:L29-L65). Il suo JSDoc suggerisce di creare resolver più specifici aggiungendo il template (core-libs/core/src/cms/page/content-page-meta.resolver.ts:L21-L28).

3.7 Breadcrumb dalle route Angular

1. `RoutingPageMetaResolver.routes$` scarta la prima route, cioè la root speciale di Angular (core-libs/core/src/cms/page/routing/routing-page-meta.resolver.ts:L47-L50).

2. Ogni route usa il resolver dichiarato in `cxPageMeta.resolver` oppure eredita quello del parent; per la prima route il default è `DefaultRoutePageMetaResolver`. L'URL assoluto si costruisce concatenando i segmenti (core-libs/core/src/cms/page/routing/routing-page-meta.resolver.ts:L64-L85).
3. `resolveBreadcrumbs(options)` per default rimuove la route corrente, a meno che `includeCurrentRoute` sia true (core-libs/core/src/cms/page/routing/routing-page-meta.resolver.ts:L91-L111). `trimCurrentRoute` rimuove anche le route finali con path `''` e poi il primo antenato con path non vuoto (core-libs/core/src/cms/page/routing/routing-page-meta.resolver.ts:L159-L173).
4. La config si legge da `route.routeConfig.data.cxPageMeta`, non da `route.data`, per evitare che le route figlie con path vuoto ereditino la config del parent (core-libs/core/src/cms/page/routing/routing-page-meta.resolver.ts:L186-L198).
5. `RoutePageMetaConfig` ha `breadcrumb?: string | RouteBreadcrumbConfig` (`{raw?, i18n?}`) e `resolver?: Type<any>` (core-libs/core/src/cms/page/routing/route-page-meta.model.ts:L30-L55). `DefaultRoutePageMetaResolver` restituisce `[]` senza config, la label letterale con `raw`, altrimenti traduce la chiave (core-libs/core/src/cms/page/routing/default-route-page-meta.resolver.ts:L36-L71).

3.8 Canonical URL (`PageLinkService`)

1. `getCanonicalUrl(options?, url?)` unisce `pageMeta.canonicalUrl` della config con le `options` passate, e prende come URL `url ?? winRef.location.href ?? ''` (core-libs/core/src/cms/page/routing/page-link.service.ts:L33-L43). In SSR `WindowRef.location` restituisce `{href: serverUrl, origin: serverOrigin}` e lancia un errore se `SERVER_REQUEST_URL` o `SERVER_REQUEST_ORIGIN` non sono forniti (core-libs/core/src/window/window-ref.ts:L70-L89).
2. Con il feature toggle `pageLinkSanitizeCanonicalUrl` l'URL viene parsato con `new URL`: i protocolli diversi da http/https e gli URL malformati diventano `''` (core-libs/core/src/cms/page/routing/page-link.service.ts:L39-L55). Il toggle vale `false` per default (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1079-L1079) e la demo lo attiva (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L367-L367).
3. `buildCanonicalUrl` applica nell'ordine `forceHttps`, `forceWww`, `removeQueryParams` e `forceTrailingSlash` (core-libs/core/src/cms/page/routing/page-link.service.ts:L57-L79). `removeQueryParams` toglie tutta la query string se l'opzione è `true`; se è un array toglie solo le chiavi elencate e conserva le altre (core-libs/core/src/cms/page/routing/page-link.service.ts:L81-L102).
4. I default sono `forceHttps: true`, `forceWww: false`, `removeQueryParams: true`, `forceTrailingSlash: true` (core-libs/core/src/cms/page/config/default-page-meta.config.ts:L41-L46).
5. Sulla PDP il canonical non parte da `location.href`. `ProductPageMetaResolver` risale ricorsivamente al `baseProduct` (scope LIST), costruisce `routingService.getFullUrl({cxRoute:'product', params: product})` e lo passa a `pageLinkService.getCanonicalUrl({}, url)` (core-libs/core/src/product/services/product-page-meta.resolver.ts:L180-L209). `getFullUrl` è `winRef.location.origin + getUrl(commands)` (core-libs/core/src/routing/facade/routing.service.ts:L119-L121). Così tutte le varianti di un prodotto puntano allo stesso URL canonico.

3.9 Resolver di prodotto, categoria e ricerca

- **PDP** (`pageType = PRODUCT_PAGE`). `product$` legge `params['productCode']` dallo stato del router e carica il prodotto con `ProductScope.DETAILS` (core-libs/core/src/product/services/product-page-meta.resolver.ts:L50-L69). Il resolver produce:
  - heading: `pageMetaResolver.product.heading` con `{heading: p.name}` (core-libs/core/src/product/services/product-page-meta.resolver.ts:L76-L84);

  - title: `name | prima categoria | manufacturer` (core-libs/core/src/product/services/product-page-meta.resolver.ts:L91-L102, core-libs/core/src/product/services/product-page-meta.resolver.ts:L151-L161);
  - description: traduzione di `pageMetaResolver.product.description` con `{description: product.summary}`, testo EN `{{description}}` (core-libs/core/src/product/services/product-page-meta.resolver.ts:L108-L116, core-libs/assets/src/translations/en/common.json:L59-L59). Come per title e heading, quindi, un override delle traduzioni cambia il risultato;
  - breadcrumb: home più un crumb per categoria (core-libs/core/src/product/services/product-page-meta.resolver.ts:L122-L139);
  - image: `images.PRIMARY.zoom.url ?? null` (core-libs/core/src/product/services/product-page-meta.resolver.ts:L145-L149);
  - robots: delegati a `BasePageMetaResolver` (core-libs/core/src/product/services/product-page-meta.resolver.ts:L163-L165).
- **Categoria** (`pageType = CATEGORY_PAGE`). `searchPage$` usa i risultati di `ProductSearchService` solo se la pagina contiene un componente `CMSProductListComponent` o `ProductGridComponent`; altrimenti usa la pagina CMS (core-libs/core/src/product/services/category-page-meta.resolver.ts:L41-L64, core-libs/core/src/product/services/category-page-meta.resolver.ts:L119-L128). Il resolver produce:
  - title: `pageMetaResolver.category.title` con `count` e `query` (core-libs/core/src/product/services/category-page-meta.resolver.ts:L66-L78);
  - breadcrumb: se la search page ha `breadcrumbs`, home e poi `/c/<code>` per le facet `category/allCategories` e `/Brands/<name>/c/<code>` per `brand`; altrimenti `[]`, cioè nessun crumb, nemmeno la home (core-libs/core/src/product/services/category-page-meta.resolver.ts:L80-L117, in particolare core-libs/core/src/product/services/category-page-meta.resolver.ts:L85-L89);
  - robots e canonical: delegati a `BasePageMetaResolver` (core-libs/core/src/product/services/category-page-meta.resolver.ts:L130-L142).
- **Ricerca** (`CONTENT_PAGE` + `SearchResultsListPageTemplate`, core-libs/core/src/product/services/search-page-meta.resolver.ts:L46-L55). Il title usa `count` dai risultati e `query` da `params['query']`, con `default_title` come fallback (core-libs/core/src/product/services/search-page-meta.resolver.ts:L35-L73). Robots e canonical sono delegati (core-libs/core/src/product/services/search-page-meta.resolver.ts:L75-L87). Non risolve breadcrumb né description.
- **Coupon**. Stesso type e template della ricerca, con +1/−1 allo score in base alla presenza del query param `couponcode` (core-libs/core/src/product/services/coupon-search-page-meta.resolver.ts:L44-L54, core-libs/core/src/product/services/coupon-search-page-meta.resolver.ts:L89-L95). Il title usa `findProductTitle` e il breadcrumb aggiunge "My coupons" solo per utenti loggati (core-libs/core/src/product/services/coupon-search-page-meta.resolver.ts:L56-L87).
- I testi EN sono in `common.json`: `category.title` "{{count}} result for {{query}}", `search.default_title` "All products", `product.title` "{{title}}" (core-libs/assets/src/translations/en/common.json:L43-L63).

3.10 Scrittura nel DOM: `SeoModule` e `SeoMetaService`

1. `SeoModule` importa `StructuredDataModule` e fornisce `provideDefaultConfig(defaultSeoConfig)`, l'`APP_INITIALIZER` `initSeoService` e `htmlLangProvider` (core-libs/storefront/cms-structure/seo/seo.module.ts:L22-L35).
2. `initSeoService` ottiene `SeoMetaService` dall'`Injector` e chiama `init()` (core-libs/storefront/cms-structure/seo/seo.module.ts:L14-L20). `init()` sottoscrive `pageMetaService.getMeta()`, filtra i `null` con `isNotNullable` e assegna il risultato al setter `meta` (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L32-L37).

3. Il setter `meta` imposta, nell'ordine, title, description, image, robots e canonicalUrl (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L39-L45). `heading` e `breadcrumbs` non finiscono in `<head>`.
   - **title**: `ngTitle.setTitle(title || '')` (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L47-L49), che in Angular assegna `document.title` (angular:packages/platform-browser/src/browser/title.ts:L36-L38);
   - **description**: `updateTag({name:'description'})` se c'è un valore, altrimenti `removeTag` (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L51-L57);
   - **image**: `og:image` scritto con l'attributo `name` e rimosso se manca (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L59-L65);
   - **robots**: se l'array non è vuoto, `content` = elementi uniti da `', '`, es. `INDEX, FOLLOW` (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L67-L71);
   - **canonical**: delegato a `pageMetaLinkService?.setCanonicalLink(url)`. `pageMetaLinkService` è un parametro opzionale del costruttore (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L23-L28, core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L79-L81).
4. `addTag` chiama `ngMeta.updateTag(meta)` solo se `meta.content` è truthy (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L83-L87). `Meta.updateTag` di Angular cerca un tag con lo stesso `name=` (o `property=`): se esiste lo aggiorna, altrimenti ne crea uno e lo appende a `<head>` (angular:packages/platform-browser/src/browser/meta.ts:L137-L146, angular:packages/platform-browser/src/browser/meta.ts:L167-L197).
5. `setCanonicalLink(url)` cerca `link[rel="canonical"]`. Senza url rimuove il link; se il link non esiste lo crea con `Renderer2` e lo appende a `head`; altrimenti ne aggiorna `href` (core-libs/storefront/cms-structure/seo/page-meta-link.service.ts:L33-L53).
6. `htmlLangProvider` è un altro `APP_INITIALIZER`: sottoscrive `languageService.getActive()` e scrive `documentElement.lang`, sostituendo `_` con `-` (core-libs/storefront/cms-structure/seo/html-lang-provider.ts:L10-L30).
7. Preconnect dei media: `MediaModule.forRoot()` registra un `APP_INITIALIZER` che chiama `MediaPreconnectService.addPreconnectLink()` (core-libs/storefront/shared/components/media/media.module.ts:L14-L18, core-libs/storefront/shared/components/media/media.module.ts:L29-L43). Il servizio aggiunge il link solo se l'origin di `mediaService.getBaseUrl()` è valido e diverso da `windowRef.location.origin` (core-libs/storefront/cms-structure/seo/media-preconnect.service.ts:L20-L34). `getBaseUrl()` usa `backend.media.baseUrl ?? backend.occ.baseUrl ?? ''` (core-libs/storefront/shared/components/media/media.service.ts:L399-L403). `addPreconnectLink` evita i duplicati e inserisce il link come primo figlio di `<head>` (core-libs/storefront/cms-structure/seo/page-meta-link.service.ts:L55-L67).

3.11 Structured data (JSON-LD)

1. `StructuredDataModule` importa ed esporta `JsonLdDirective` e registra un `APP_INITIALIZER` che chiama `StructuredDataFactory.build()` (core-libs/storefront/cms-structure/seo/structured-data/structured-data.module.ts:L16-L36).
2. `StructuredDataFactory` inietta `SCHEMA_BUILDER` con `@Optional()`. `build()` procede solo se `isJsonLdRequired()` è vero e se ci sono builder (core-libs/storefront/cms-structure/seo/structured-data/structured-data.factory.ts:L20-L42).
3. `isJsonLdRequired()` è vero sul server, oppure in dev mode quando `disableInDevMode` non è true (core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L46-L51). Il default è `disableInDevMode: true` (core-libs/storefront/cms-structure/seo/config/default-seo.config.ts:L9-L15), quindi **per default il JSON-LD si genera solo in SSR**.

4. `collectSchemas()` fa `combineLatest` dei `build()` di tutti gli schema builder, e ogni emissione (l'array degli schemi) va a `scriptBuilder.build(schema)` (core-libs/storefront/cms-structure/seo/structured-data/structured-data.factory.ts:L36-L49).
5. `JsonLdScriptFactory.build` scrive nel `textContent` di un unico `<script id="json-ld" type="application/ld+json">`, appeso al `body` alla prima chiamata (core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L35-L39, core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L62-L76). Il contenuto passa da `escapeHtml`, che serializza con `JSON.stringify`, assegna il risultato a `div.textContent` e restituisce `innerHTML`, per evitare l'XSS (core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L78-L88).
6. I builder standard sono registrati da `JsonLdBuilderModule`: `SCHEMA_BUILDER` → `ProductSchemaBuilder` e `BreadcrumbSchemaBuilder`; `JSONLD_PRODUCT_BUILDER` → base product, offer e review (core-libs/storefront/cms-structure/seo/structured-data/builders/json-ld-builder.module.ts:L21-L52). **Questo modulo è opt-in**: né `SeoModule` né `StructuredDataModule` lo importano, mentre la demo lo importa esplicitamente (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L246-L247).
7. `ProductSchemaBuilder` parte da `CurrentProductService.getProduct()`. Se c'è un prodotto, combina `{@context, @type:'Product'}` con i risultati dei `JsonLdBuilder` iniettati e li unisce con `Object.assign`; altrimenti emette `{}` (core-libs/storefront/cms-structure/seo/structured-data/builders/product/product-schema.builder.ts:L31-L58). I tre sotto-builder producono:
   - `JsonLdBaseProductBuilder`: `sku`, `name`, `description` (summary), `brand` (manufacturer) e `image` (core-libs/storefront/cms-structure/seo/structured-data/builders/product/jsonld-base-product.builder.ts:L20-L60);
   - `JsonLdProductOfferBuilder`: `offers` con price, currency e availability (core-libs/storefront/cms-structure/seo/structured-data/builders/product/jsonld-product-offer.builder.ts:L20-L36);
   - `JsonLdProductReviewBuilder`: `aggregateRating` e `review[]` se c'è almeno una recensione (core-libs/storefront/cms-structure/seo/structured-data/builders/product/jsonld-product-review.builder.ts:L27-L82).
8. `BreadcrumbSchemaBuilder` trasforma `pageMeta.breadcrumbs` in `ListItem` con `position` e `item:{@id: link, name: label}`, aggiunge il title come ultimo elemento e restituisce un `BreadcrumbList` (core-libs/storefront/cms-structure/seo/structured-data/builders/breadcrumb/breadcrumb-schema.builder.ts:L19-L56).
9. `JsonLdDirective` (`[cxJsonLd]`) appende uno script escapato all'elemento host, se `isJsonLdRequired()`. Secondo il JSDoc Spartacus non la usa: è pensata per i merchant (core-libs/storefront/cms-structure/seo/structured-data/json-ld.directive.ts:L10-L47).

3.12 PWA: service worker

1. `PwaModule` importa `ServiceWorkerModule.register('ngsw-worker.js')`, `I18nModule` e i due componenti standalone, che esporta (core-libs/storefront/cms-structure/pwa/pwa.module.ts:L32-L56).
2. `ServiceWorkerModule.register` chiama `provideServiceWorker`, che fornisce `SwRegistrationOptions` con `useValue: options` e registra un app initializer (angular:packages/service-worker/src/module.ts:L30-L38, angular:packages/service-worker/src/provider.ts:L240-L254).
3. `PwaModule` sovrascrive `SwRegistrationOptions` con `pwaConfigurationFactory`, che restituisce `enabled: true` solo fuori da dev mode e con `pwa.enabled` (core-libs/storefront/cms-structure/pwa/pwa.module.ts:L19-L23, core-libs/storefront/cms-structure/pwa/pwa.module.ts:L42-L46).
4. `ngswAppInitializer` termina subito in SSR (`ngServerMode`), quando `options.enabled === false` o quando `serviceWorker` non è disponibile in `navigator` (angular:packages/service-worker/src/provider.ts:L32-

L41). Senza `registrationStrategy` la strategia è `'registerWhenStable:30000'` (angular:packages/service-worker/src/provider.ts:L69-L73).

5. Nella demo: `pwa: { enabled: false, addToHomeScreen: true }` (projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L49-L54), build prod con `"serviceWorker": false` (projects/storefrontapp/project.json:L169-L169), e `index.html` che linka `manifest.json` (projects/storefrontapp/src/index.html:L6-L6), incluso negli assets (projects/storefrontapp/project.json:L26-L26).

3.13 PWA: Add to Home Screen

1. `PwaModule` registra l'`APP_INITIALIZER` `pwaFactory`, che ha come dipendenza `AddToHomeScreenService`. Lo scopo è istanziare il servizio all'avvio: la funzione restituita si limita a ritornarlo (core-libs/storefront/cms-structure/pwa/pwa.module.ts:L25-L30, core-libs/storefront/cms-structure/pwa/pwa.module.ts:L47-L52).
2. Il costruttore di `AddToHomeScreenService` chiama `init()` solo se `pwa.addToHomeScreen` è true (core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L26-L34).
3. `init()` registra i listener solo se esiste `nativeWindow`, che in SSR è `undefined` (core-libs/core/src/window/window-ref.ts:L41-L44). Su `beforeinstallprompt` chiama `preventDefault`, salva l'evento e abilita il prompt. Su `appinstalled` mostra il global message `pwa.addedToHomeScreen` di tipo CONFIRMATION, disabilita il prompt e azzera l'evento (core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L36-L57).
4. `canPrompt$` deriva da un `BehaviorSubject<boolean>(false)`; `firePrompt()` chiama `deferredEvent.prompt()` se l'evento è presente (core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L20-L24, core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L67-L71).
5. La base astratta `AddToHomeScreenComponent` (`@Directive()`) espone `canPrompt$` in `ngOnInit`, e `prompt()` chiama `firePrompt()` (core-libs/storefront/cms-structure/pwa/components/add-to-home-screen.component.ts:L11-L23).
6. `cx-add-to-home-screen-banner` mostra descrizione, due vantaggi e il bottone solo quando `canPrompt$` è true (core-libs/storefront/cms-structure/pwa/components/add-to-home-screen-banner/add-to-home-screen-banner.component.html:L1-L16). `cx-add-to-home-screen-btn` proietta il contenuto solo se `canPrompt$` è true, dentro uno `<span (click)="prompt()">` (core-libs/storefront/cms-structure/pwa/components/add-to-home-screen-btn/add-to-home-screen-btn.component.html:L1-L3).
7. Il banner compare nel messaggio di ringraziamento della conferma d'ordine (feature-libs/order/components/order-confirmation/order-confirmation-thank-you-message/order-confirmation-thank-you-message.component.html:L26-L26), e `OrderConfirmationModule` importa `PwaModule` (feature-libs/order/components/order-confirmation/order-confirmation.module.ts:L56-L56).

---

5. Estratti di codice reale

5.1 Lo scoring dei resolver

core-libs/core/src/cms/page/page-meta.resolver.ts:L31-L53

```ts
getScore(page: Page): number {
  let score = 0;
  if (this.pageType) {
    score += page.type === this.pageType ? 1 : -1;
  }
  if (this.pageTemplate) {
    score += page.template === this.pageTemplate ? 1 : -1;
  }

  if (this.pageUid) {
    score += page.pageId === this.pageUid ? 10 : -10;
  }

  return score;
}

hasMatch(page: Page): boolean {
  return this.getScore(page) > 0;
}

getPriority(page: Page): number {
  return this.getScore(page);
}
```

5.2 Pipeline `meta$` e composizione

core-libs/core/src/cms/facade/page-meta.service.ts:L59-L68

```ts
protected meta$: Observable<PageMeta | null> = defer(() =>
  this.cms.getCurrentPage()
).pipe(
```

```
    filter((page) => Boolean(page)),
    switchMap((page: Page) => this.getMetaResolver(page)),
    switchMap((metaResolver: PageMetaResolver | undefined) =>
      metaResolver ? this.resolve(metaResolver) : of(null)
    ),
    shareReplay({ bufferSize: 1, refCount: true })
  );
```

core-libs/core/src/cms/facade/page-meta.service.ts:L84-L103

```ts
  protected resolve(metaResolver: PageMetaResolver): Observable<PageMeta> {
    const resolverMethods = this.getResolverMethods();
    const resolvedData: Observable<PageMeta>[] = Object.keys(resolverMethods)
      // TODO: Revisit if typing is possible here with Template Literal Types when we update to TS >=4.1
      .filter((key) => (metaResolver as any)[resolverMethods[key]])
      .map((key) => {
        return (metaResolver as any)
          [resolverMethods[key]]()
          .pipe(map((data) => ({ [key]: data })));
      });

    if (resolvedData.length === 0) {
      // uniteLatest will fail otherwise
      return of({});
    } else {
      return uniteLatest(resolvedData).pipe(
        map((data) => Object.assign({}, ...data))
      );
    }
  }
```

5.3 Selezione con parità a favore dell'ultimo provider

core-libs/core/src/util/applicable.ts:L76-L87

```ts
  let lastPriority = -Infinity;
  return matchedApplicables.reduce((acc: T | undefined, curr: T) => {
    const currPriority = curr.getPriority
      ? curr.getPriority(...priorityParams)
      : Priority.NORMAL;
    if (lastPriority > currPriority) {
      return acc;
    }
    lastPriority = currPriority;
    return curr;
  }, undefined);
}
```

5.4 Normalizzazione del canonical

core-libs/core/src/cms/page/routing/page-link.service.ts:L57-L79

```ts
protected buildCanonicalUrl(
  url: string,
  options: CanonicalUrlOptions
): string {
  if (options.forceHttps) {
    url = url.replace(/^http(?!s):/i, 'https:');
  }

  if (options.forceWww) {
    // this will not allow for not adding wwww. in case of a subdomain
    url = url.replace(/^(https?:\/\/)(?!www\.)(.*)/i, '$1www.$2');
  }

  if (options.removeQueryParams) {
    url = this.removeQueryParams(url, options);
  }

  if (options.forceTrailingSlash) {
    url = url.replace(/^([^\?]+[^\/\?]$)$/i, '$1/');
  }

  return url;
}
```

5.5 I setter di `SeoMetaService`

core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L39-L71

```ts
protected set meta(meta: PageMeta) {
  this.title = meta.title;
  this.description = meta.description;
  this.image = meta.image;
  this.robots = meta.robots;
  this.canonicalUrl = meta.canonicalUrl;
}

protected set title(title: string | undefined) {
  this.ngTitle.setTitle(title || '');
}

protected set description(value: string | undefined) {
  if (value) {
    this.addTag({ name: 'description', content: value });
  } else {
    this.ngMeta.removeTag('name="description"');
```

```
    }
  }

  protected set image(imageUrl: string | undefined) {
    if (imageUrl) {
      this.addTag({ name: 'og:image', content: imageUrl });
    } else {
      this.ngMeta.removeTag('name="og:image"');
    }
  }

  protected set robots(value: PageRobotsMeta[] | undefined) {
    if (value?.length) {
      this.addTag({ name: 'robots', content: value.join(', ') });
    }
  }
```

5.6 Quando si genera il JSON-LD, e come viene protetto

core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L46-L51

```ts
  isJsonLdRequired(): boolean {
    return (
      !isPlatformBrowser(this.platformId) ||
      (isDevMode() && !this.config.seo?.structuredData?.disableInDevMode)
    );
  }
```

core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L84-L88

```ts
  escapeHtml(schema: {}): string {
    const div: HTMLScriptElement = this.renderer.createElement('div');
    div.textContent = JSON.stringify(schema);
    return div.innerHTML;
  }
```

5.7 Abilitazione del service worker

core-libs/storefront/cms-structure/pwa/pwa.module.ts:L19-L30

```ts
export function pwaConfigurationFactory(
  pwaConfig: PWAModuleConfig
): SwRegistrationOptions {
  return { enabled: (!isDevMode() && pwaConfig.pwa?.enabled) || false };
}

export function pwaFactory(
```

```
  addToHomeScreenService: AddToHomeScreenService
): any {
  const result = () => addToHomeScreenService;
  return result;
}
```

5.8 Listener Add to Home Screen

core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L36-L57

```ts
  init() {
    if (this.winRef.nativeWindow) {
      this.winRef.nativeWindow.addEventListener(
        'beforeinstallprompt',
        (event) => {
          event.preventDefault();
          this.deferredEvent = event;
          this.enableAddToHomeScreen();
        }
      );

      this.winRef.nativeWindow.addEventListener('appinstalled', () => {
        this.globalMessageService.add(
          { key: 'pwa.addedToHomeScreen' },
          GlobalMessageType.MSG_TYPE_CONFIRMATION
        );

        this.disableAddToHomeScreen();
        this.deferredEvent = null;
      });
    }
  }
```

6. Configurazione

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
pageMeta.resolvers	PageMetaResolverConfig[] ({property, method})	7 voci (title, heading, breadcrumbs, description, image, robots, canonicalUrl)	core-libs/core/src/cms/page/config/page-meta.config.ts:L22-L41; default core-libs/core/src/cms/page/config/default-page-meta.config.ts:L11-L40	core-libs/core/src/cms/facade/page-meta.service.ts:L115-L125
pageMeta.canonicalUrl.forceHttps	boolean	true	core-libs/core/src/cms/page/config/page-meta.config.ts:L49-L52; default core-libs/core/src/cms/page/config/default-page-meta.config.ts:L42-L42	core-libs/core/src/cms/page/routing/page-link.service.ts:L61-L63

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
pageMeta.canonicalUrl.forceWww	boolean	false	core-libs/core/src/cms/page/config/page-meta.config.ts:L54-L59; default core-libs/core/src/cms/page/config/default-page-meta.config.ts:L43-L43	core-libs/core/src/cms/page/routing/page-link.service.ts:L65-L68
pageMeta.canonicalUrl.removeQueryParams	boolean | string[]	true	core-libs/core/src/cms/page/config/page-meta.config.ts:L61-L70; default core-libs/core/src/cms/page/config/default-page-meta.config.ts:L44-L44	core-libs/core/src/cms/page/routing/page-link.service.ts:L70-L72, core-libs/core/src/cms/page/routing/page-link.service.ts:L81-L102
pageMeta.canonicalUrl.forceTrailingSlash	boolean	true	core-libs/core/src/cms/page/config/page-meta.config.ts:L44-L47; default core-libs/core/src/cms/page/config/default-page-meta.config.ts:L45-L45	core-libs/core/src/cms/page/routing/page-link.service.ts:L74-L76
seo.structuredData.disableInDevMode	boolean	true	core-libs/storefront/cms-structure/seo/config/seo.config.ts:L18-L24; default core-libs/storefront/cms-structure/seo/config/default-seo.config.ts:L9-L15	core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L46-L51
pwa.enabled	boolean	false	core-libs/storefront/cms-structure/pwa/pwa.module-config.ts:L14-L26	core-libs/storefront/cms-structure/pwa/pwa.module.ts:L19-L23
pwa.addToHomeScreen	boolean	false	core-libs/storefront/cms-structure/pwa/pwa.module-config.ts:L14-L26	core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L31-L33
feature toggle pageLinkSanitizeCanonicalUrl	boolean	false	core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L511-L518, core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1079-L1079	core-libs/core/src/cms/page/routing/page-link.service.ts:L39-L41
route data.cxPageMeta	RoutePageMetaConfig	—	core-libs/core/src/cms/page/routing/route-page-meta.model.ts:L16-L40	core-libs/core/src/cms/page/routing/routing-page-meta.resolver.ts:L186-L198

Le tre classi di config sono abstract `useExisting: Config` e aumentano `Config` tramite module augmentation: `PageMetaConfig` (core-libs/core/src/cms/page/config/page-meta.config.ts:L10-L20), `SeoConfig` (core-libs/storefront/cms-structure/seo/config/seo.config.ts:L10-L28) e `PWAModuleConfig` (core-libs/storefront/cms-structure/pwa/pwa.module-config.ts:L10-L30). Si configurano quindi con `provideConfig({...})` come qualsiasi altra chiave (vedi 11 — Configurazione).

Esempio di config (illustrativo, basato sui tipi `CanonicalUrlOptions` in core-libs/core/src/cms/page/config/page-meta.config.ts:L43-L71 e `PWAModuleConfig` in core-libs/storefront/cms-structure/pwa/pwa.module-config.ts:L14-L19):

```ts
provideConfig({
  pageMeta: {
    canonicalUrl: {
      forceWww: true,
      removeQueryParams: ['utm_source', 'utm_medium'],
    },
  },
  pwa: { enabled: true, addToHomeScreen: true },
});
```

Nota: `pageMeta.resolvers` è un array, e il deep merge della config sostituisce gli array invece di concatenarli. Una config custom deve quindi elencare anche le voci di default che vuole mantenere. `Config` è costruita da `deepMerge({}, inject(DefaultConfig), inject(RootConfig))` (core-libs/core/src/config/config-tokens.ts:L10-L12). `deepMerge` scende ricorsivamente solo nei valori per cui `isObject` è vero, e `isObject` esclude gli array: un array viene assegnato così com'è (core-libs/core/src/config/utils/deep-merge.ts:L7-L9, core-libs/core/src/config/utils/deep-merge.ts:L38-L45). Per i dettagli sul merge vedi 11 — Configurazione.

---

7. Commenti e note notevoli dal sorgente

- `// @deprecated (will be removed in 12 months)` sul parametro `platformId` di `PageMetaService` (core-libs/core/src/cms/facade/page-meta.service.ts:L39-L40).
- `// NOTE: Solution to the issue: https://jira.tools.sap/browse/CXSPA-10923`: il cambio lingua forza il ricaricamento della pagina CMS per aggiornare il title, saltando la prima emissione per non duplicare il refresh all'avvio (core-libs/core/src/cms/facade/page-meta.service.ts:L42-L44).
- `// TODO: Revisit if typing is possible here with Template Literal Types when we update to TS >=4.1`: il codice è su TypeScript 5.9 ma il TODO è ancora lì (core-libs/core/src/cms/facade/page-meta.service.ts:L87-L87).
- `// uniteLatest will fail otherwise`: giustifica il ramo `of({})` (core-libs/core/src/cms/facade/page-meta.service.ts:L96-L96).
- `// this will not allow for not adding wwww. in case of a subdomain`: `forceWww` non riconosce i sottodomini (core-libs/core/src/cms/page/routing/page-link.service.ts:L66-L66), come dice anche il JSDoc della config (core-libs/core/src/cms/page/config/page-meta.config.ts:L54-L59).
- Il JSDoc di `ProductPageMetaResolver.resolveCanonicalUrl` ammette due limiti: con varianti multi-livello OCC espone solo il `baseProduct` diretto, e l'URL della variante contiene solo il codice prodotto, non dati per URL "pretty" (core-libs/core/src/product/services/product-page-meta.resolver.ts:L167-L179).
- JSDoc di `JsonLdDirective`: "This helper directive is actually not used in Spartacus" (core-libs/storefront/cms-structure/seo/structured-data/json-ld.directive.ts:L10-L20).
- JSDoc di `escapeHtml`: "The given schema is not trusted, as malicious code could be injected (XSS)" (core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L78-L83).
- Canonical: la rimozione del link è un "edge case, but useful if the canonical url is created in CSR while developing/testing" (core-libs/storefront/cms-structure/seo/page-meta-link.service.ts:L38-L42), e il JSDoc del setter dice che i canonical "are (typically) only added in SSR" (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L73-L78).
- Preconnect: "we want the preconnect-link to be at the top of the <head> section" (core-libs/storefront/cms-structure/seo/page-meta-link.service.ts:L66-L66), e non serve se il dominio dei media

coincide con quello della storefront (core-libs/storefront/cms-structure/seo/media-preconnect.service.ts:L29-L30).

- La nota lunga sull'uso di `routeConfig.data` invece di `data` spiega l'ereditarietà di `data` per le route figlie con path `''` (core-libs/core/src/cms/page/routing/routing-page-meta.resolver.ts:L189-L196).
- Il JSDoc di `PageHeadingResolver` invita ad aggiungere resolver custom "to the list of `PageMetaService.resolverMethods`", ma quella proprietà non esiste: la mappa è una variabile locale costruita da `getResolverMethods()` sulla config `pageMeta.resolvers` (core-libs/core/src/cms/page/page.resolvers.ts:L17-L18, core-libs/core/src/cms/facade/page-meta.service.ts:L84-L86).

8. Extension point

EXTENSION POINT	COME	SORGENTE	RICETTA
Nuovo resolver di pagina	estendere `PageMetaResolver`, impostare `pageType`/`pageTemplate`/`pageUid`, implementare i `resolve*` e fare multi-provide sul token `PageMetaResolver`	core-libs/core/src/cms/page/page-meta.resolver.ts:L17-L54; registrazione d'esempio core-libs/core/src/cms/page/page-meta.module.ts:L13-L21	52 — Ricette OCC, meta resolver
Riuso dei comportamenti standard	iniettare `BasePageMetaResolver` e delegare, come fa `ContentPageMetaResolver`	core-libs/core/src/cms/page/base-page-meta.resolver.ts:L25-L108, core-libs/core/src/cms/page/content-page-meta.resolver.ts:L41-L64	52
Specializzare un resolver di prodotto	estendere `ProductPageMetaResolver` / `CategoryPageMetaResolver` / `SearchPageMetaResolver` (esportati) e registrarlo dopo l'originale, o con score più alto	export core-libs/core/src/product/services/index.ts:L7-L9; registrazione core-libs/core/src/product/product.module.ts:L16-L37	52
Nuova proprietà di meta	aggiungere `{property, method}` a `pageMeta.resolvers`, ripetendo anche le 7 voci di default perché l'array custom sostituisce quello di default (sezione 6), e implementare il metodo sul resolver	core-libs/core/src/cms/page/config/page-meta.config.ts:L22-L41, core-libs/core/src/cms/facade/page-meta.service.ts:L84-L103	50 — Ricette config e DI
Regole del canonical	config `pageMeta.canonicalUrl`, oppure override di `PageLinkService` (metodi `protected` `buildCanonicalUrl`, `removeQueryParams`, `sanitizeUrl`)	core-libs/core/src/cms/page/routing/page-link.service.ts:L45-L102	50
Breadcrumb di route Angular	`data: { cxPageMeta: { breadcrumb, resolver } }` sulla route; resolver custom che estende `DefaultRoutePageMetaResolver`	core-libs/core/src/cms/page/routing/route-page-meta.model.ts:L30-L55, core-libs/core/src/cms/page/routing/default-route-page-meta.resolver.ts:L21-L79	51 — Ricette CMS, outlet, route
Scrittura dei tag	sostituire `SeoMetaService` via DI e ridefinire i setter `protected` (es. `og:image` con `property`, robots rimovibile)	core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L39-L87	50
Canonical/preconnect nel DOM	override di `PageMetaLinkService` o `MediaPreconnectService`	core-libs/storefront/cms-structure/seo/page-meta-link.service.ts:L33-L71, core-libs/storefront/cms-structure/seo/media-preconnect.service.ts:L20-L34	50

EXTENSION POINT	COME	SORGENTE	RICETTA
Nuovo schema JSON-LD	classe che implementa `SchemaBuilder` e multi-provide su `SCHEMA_BUILDER`	core-libs/storefront/cms-structure/seo/structured-data/builders/schema.interface.ts:L9-L11, core-libs/storefront/cms-structure/seo/structured-data/builders/tokens.ts:L15-L15	50
Campi aggiuntivi nello schema Product	`JsonLdBuilder<Product>` in multi-provide su `JSONLD_PRODUCT_BUILDER`	core-libs/storefront/cms-structure/seo/structured-data/builders/tokens.ts:L21-L23, core-libs/storefront/cms-structure/seo/structured-data/builders/product/product-schema.builder.ts:L44-L58	50
Schema statico in un componente	direttiva `[cxJsonLd]`	core-libs/storefront/cms-structure/seo/structured-data/json-ld.directive.ts:L21-L47	51
UI Add to Home Screen custom	estendere `AddToHomeScreenComponent` o usare `AddToHomeScreenService` (`canPrompt$`, `firePrompt`, `enableAddToHomeScreen`, `disableAddToHomeScreen`)	core-libs/storefront/cms-structure/pwa/components/add-to-home-screen.component.ts:L11-L23, core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L59-L71	51
Opzioni del service worker	sovrascrivere `SwRegistrationOptions` (es. `registrationStrategy`) dopo `PwaModule`	core-libs/storefront/cms-structure/pwa/pwa.module.ts:L42-L46, angular:packages/service-worker/src/provider.ts:L69-L73	50

Esempio di resolver custom per una pagina di contenuto con template specifico. È illustrativo e usa solo simboli esportati da `@spartacus/core`: `PageMetaResolver` (core-libs/core/src/cms/page/index.ts:L11-L11), `BasePageMetaResolver` (core-libs/core/src/cms/page/index.ts:L7-L7), interfacce `Page*Resolver` (core-libs/core/src/cms/page/index.ts:L12-L12).

```ts
@Injectable({ providedIn: 'root' })
export class StorePageMetaResolver
  extends PageMetaResolver
  implements PageTitleResolver, PageRobotsResolver, CanonicalPageResolver
{
  constructor(protected base: BasePageMetaResolver) {
    super();
    this.pageType = PageType.CONTENT_PAGE;     // +1
    this.pageTemplate = 'StoreFinderPageTemplate'; // +1 → score 2 > ContentPageMetaResolver (1)
  }
  resolveTitle() { return this.base.resolveTitle(); }
  resolveRobots() { return this.base.resolveRobots(); }
  resolveCanonicalUrl() { return this.base.resolveCanonicalUrl({ forceWww: true }); }
}
// provider: { provide: PageMetaResolver, useExisting: StorePageMetaResolver, multi: true }
```

DA VERIFICARE: il nome di template `'StoreFinderPageTemplate'` è solo un esempio e non è stato verificato nei dati CMS. I template reali dipendono dal backend.

Per l'API pubblica e la stabilità negli upgrade (per esempio `CouponSearchPageResolver` non esportato, toggle `pageLinkSanitizeCanonicalUrl`) vedi 54 — API pubblica e upgrade e 42 — Feature toggle e deprecazioni.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. **Un resolver che non emette blocca tutti i meta.** `resolve()` combina i metodi con `uniteLatest`, che è un `combineLatest` (core-libs/core/src/util/rxjs/unite-latest.ts:L45-L45), e `combineLatest` emette solo dopo che tutte le sorgenti hanno emesso (deps:rxjs-7.8.2/package/src/internal/observable/combineLatest.ts:L242-L269). Un esempio concreto: `CategoryPageMetaResolver.resolveTitle` filtra le pagine senza `pagination` (core-libs/core/src/product/services/category-page-meta.resolver.ts:L66-L69), e se la pagina categoria non contiene un componente PLP `searchPage$` emette la `Page` CMS, che non ha `pagination` (core-libs/core/src/product/services/category-page-meta.resolver.ts:L45-L52). In quel caso `meta$` non emette per quella pagina. DA VERIFICARE a runtime: è una deduzione dal codice, che non tiene conto di eventuali proprietà `pagination` aggiunte alla `Page` da normalizer custom.
2. **Il robots meta non viene mai rimosso.** Il setter non ha un ramo `else` (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L67-L71). Se si naviga da una pagina `NOINDEX` a una con `robots` vuoto (array vuoto quando il backend non manda `robotTag`, core-libs/core/src/occ/adapters/cms/converters/occ-cms-page-normalizer.ts:L198-L222), in CSR il vecchio tag resta nel DOM.
3. `og:image` **con** `name` **invece di** `property`**.** Open Graph usa `property`, ma Spartacus scrive `{ name: 'og:image' }` (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L59-L65). Angular usa `name` come selettore quando è presente (angular:packages/platform-browser/src/browser/meta.ts:L194-L197).
4. **Niente JSON-LD senza** `JsonLdBuilderModule`**.** Il modulo non è importato da `SeoModule` né da `StructuredDataModule`. Senza di esso `SCHEMA_BUILDER` è vuoto e `build()` non fa nulla (core-libs/storefront/cms-structure/seo/structured-data/structured-data.factory.ts:L35-L35). La demo lo importa a mano (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L246-L247), mentre un grep su `core-libs/schematics` non trova alcuna occorrenza di `JsonLdBuilderModule`: la schematic non lo genera.
5. **JSON-LD solo in SSR.** In browser in produzione `isJsonLdRequired()` è false, e in dev è spento da `disableInDevMode: true` (core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L46-L51, core-libs/storefront/cms-structure/seo/config/default-seo.config.ts:L11-L13). Chi testa con `ng serve` non vede lo script finché non imposta `disableInDevMode: false`.
6. **Schema del breadcrumb e** `null` **nell'array.** Senza breadcrumb, `BreadcrumbSchemaBuilder.collect` restituisce `undefined` (core-libs/storefront/cms-structure/seo/structured-data/builders/breadcrumb/breadcrumb-schema.builder.ts:L25-L28), che entra nell'array passato a `escapeHtml` (core-libs/storefront/cms-structure/seo/structured-data/structured-data.factory.ts:L47-L49). `JSON.stringify` serializza un `undefined` dentro un array come `null`. Inoltre l'ultimo `ListItem` usa il title come `@id`, non un URL (core-libs/storefront/cms-structure/seo/structured-data/builders/breadcrumb/breadcrumb-schema.builder.ts:L40-L49).
7. **Dettagli schema.org discutibili.** `@context` è `http://schema.org` (core-libs/storefront/cms-structure/seo/structured-data/builders/product/product-schema.builder.ts:L52-L55). Il `@type` delle recensioni è `'review'` minuscolo (core-libs/storefront/cms-structure/seo/structured-data/builders/product/jsonld-product-review.builder.ts:L55-L57). `datePublished` non ha zero iniziali e usa l'ora locale (core-libs/storefront/cms-structure/seo/structured-data/builders/product/jsonld-product-review.builder.ts:L62-L67). `availability` vale `'InStock'`/`'OutOfStock'` senza prefisso URL, e `lowStock` finisce

in `OutOfStock` (core-libs/storefront/cms-structure/seo/structured-data/builders/product/jsonld-product-offer.builder.ts:L30-L33).

8. **Parità di score.** A parità vince il provider registrato per ultimo (core-libs/core/src/util/applicable.ts:L81-L85). Un resolver custom con lo stesso score di uno standard vince solo se è registrato dopo; per non dipendere dall'ordine conviene alzare lo score con `pageTemplate` o `pageUid`.
9. `CouponSearchPageResolver` **e** `ActivatedRoute`**.** Il getter `couponCode` legge `this.route.snapshot?.queryParams?.couponcode` da un `ActivatedRoute` iniettato in un servizio root (core-libs/core/src/product/services/coupon-search-page-meta.resolver.ts:L48-L48, core-libs/core/src/product/services/coupon-search-page-meta.resolver.ts:L93-L95). Nell'injector root Angular fornisce `routerState.root` (angular:packages/router/src/provide_router.ts:L112-L120), e lo snapshot root riceve i query params dell'URL (angular:packages/router/src/recognize.ts:L122-L126), quindi il parametro è visibile. DA VERIFICARE il timing: lo score è calcolato quando cambia la pagina CMS, e non è stato verificato che in quel momento lo snapshot della root sia già quello della nuova navigazione.
10. `CouponSearchPageResolver` **non è esportato** dal barrel `core-libs/core/src/product/services/index.ts` (core-libs/core/src/product/services/index.ts:L7-L11), quindi non si può estendere importandolo da `@spartacus/core`.
11. `forceTrailingSlash` **e query residue.** La regex esclude `?`: se `removeQueryParams` è un array e restano parametri, la slash finale non viene aggiunta (core-libs/core/src/cms/page/routing/page-link.service.ts:L74-L76).
12. `forceWww` **sui sottodomini.** Produce `www.shop.example.com` (core-libs/core/src/cms/page/routing/page-link.service.ts:L65-L68).
13. **Sanitize del canonical spento per default.** Senza il toggle, un `location.href` con protocollo non http finisce nel canonical (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1079-L1079, core-libs/core/src/cms/page/routing/page-link.service.ts:L39-L42).
14. **Le** `CanonicalUrlOptions` **per-chiamata non arrivano dal flusso standard.** `PageMetaService.resolve` invoca i metodi senza argomenti (core-libs/core/src/cms/facade/page-meta.service.ts:L89-L92). Il parametro `options` di `BasePageMetaResolver.resolveCanonicalUrl` è utile solo se un resolver custom lo passa esplicitamente, come nell'esempio della sezione 8.
15. `resolveImage` **della PDP restituisce** `null` pur avendo tipo `Observable<string>` (core-libs/core/src/product/services/product-page-meta.resolver.ts:L145-L149). `SeoMetaService` lo tratta come falsy e rimuove il tag (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L59-L65).
16. **Preconnect con URL completo.** `MediaPreconnectService` controlla l'origin ma passa a `addPreconnectLink` l'URL intero restituito da `getBaseUrl()` (core-libs/storefront/cms-structure/seo/media-preconnect.service.ts:L21-L32).
17. `htmlLangProvider` **non esportato e mai chiuso.** Non compare in `seo/index.ts` (core-libs/storefront/cms-structure/seo/index.ts:L7-L12), e la subscription a `getActive()` non viene mai annullata (core-libs/storefront/cms-structure/seo/html-lang-provider.ts:L24-L27).
18. **Service worker spento in dev, e la demo non lo genera.** `!isDevMode()` blocca la registrazione anche con `pwa.enabled: true` (core-libs/storefront/cms-structure/pwa/pwa.module.ts:L22-L22). La build prod della demo ha `serviceWorker: false` (projects/storefrontapp/project.json:L169-L169), quindi `ngsw-worker.js` non viene prodotto. Per attivare davvero la PWA servono `pwa.enabled`, una build con service worker e una configurazione ngsw. In `projects/storefrontapp` non c'è un `ngsw-config.json`. Spartacus ne fornisce uno di riferimento in `core-libs/storefront/cms-structure/pwa/ngsw-config.json` (core-libs/storefront/cms-structure/pwa/ngsw-config.json:L1-L6), che la demo non usa: la sua build prod ha `"serviceWorker": false` (projects/storefrontapp/project.json:L169-L169).
19. `PwaModule` **importato due volte.** Lo importano sia `BaseStorefrontModule` (core-libs/storefront/base-storefront.module.ts:L33-L33) sia `OrderConfirmationModule` (feature-libs/order/components/order-confirmation/order-confirmation.module.ts:L56-L56). DA VERIFICARE l'effetto runtime quando

`OrderConfirmationModule` è caricato in lazy: `ServiceWorkerModule.register` e l'`APP_INITIALIZER` verrebbero ri-dichiarati nell'injector della feature.

20. **Listener mai rimossi e bottone poco accessibile.** I listener `beforeinstallprompt`/`appinstalled` non vengono mai rimossi (core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L36-L57). Nel bottone, lo `<span (click)>` è sempre renderizzato e non ha `role` né `tabindex`, quindi non è raggiungibile da tastiera (core-libs/storefront/cms-structure/pwa/components/add-to-home-screen-btn/add-to-home-screen-btn.component.html:L1-L3).
21. **Errore con provider non multi.** `UnifiedInjector.getMulti` lancia `Multi-providers mixed with single providers` se `PageMetaResolver` è fornito senza `multi: true` in un injector (core-libs/core/src/lazy-loading/unified-injector.ts:L83-L88).
22. **JSDoc fuorvianti.** `SearchPageMetaResolver` cita `PageType.CATEGORY_PAGE` ma imposta `CONTENT_PAGE` (core-libs/core/src/product/services/search-page-meta.resolver.ts:L22-L27, core-libs/core/src/product/services/search-page-meta.resolver.ts:L53-L53). `CategoryPageMetaResolver` dice "title, and breadcrumbs only" ma risolve anche robots e canonical (core-libs/core/src/product/services/category-page-meta.resolver.ts:L28-L32, core-libs/core/src/product/services/category-page-meta.resolver.ts:L130-L142). `setCanonicalLink` parla di un "id" che il metodo non accetta (core-libs/storefront/cms-structure/seo/page-meta-link.service.ts:L27-L33).
23. **Field initializer che dipende dal costruttore.** In `JsonLdScriptFactory`, `renderer` è inizializzato con `this.rendererFactory`, una parameter property (core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L23-L33). Funziona perché il `tsconfig.json` di root imposta `"useDefineForClassFields": false` (tsconfig.json:L799-L799) e la libreria lo eredita (core-libs/storefront/tsconfig.lib.json:L1-L5). Attivare quell'opzione romperebbe la classe.
24. **Cambio lingua = nuovo load CMS.** Ogni cambio di lingua attiva dopo il primo dispatcha `LoadCmsPageData` (core-libs/core/src/cms/facade/page-meta.service.ts:L42-L50, core-libs/core/src/cms/facade/cms.service.ts:L197-L204), anche se gli unici dati da aggiornare fossero i meta.

---

10. Come fare debug

- **Il title non cambia.** Verificare prima che arrivi un `PageMeta`: sottoscrivere `PageMetaService.getMeta()` in un componente di test e loggare. `null` significa che nessun resolver ha score > 0 (core-libs/core/src/cms/facade/page-meta.service.ts:L64-L66). Se invece non arriva nulla, uno dei `resolve*` del resolver scelto non emette (trappola 1). Per capirlo, sottoscrivere singolarmente i metodi elencati in `pageMeta.resolvers` (core-libs/core/src/cms/page/config/default-page-meta.config.ts:L11-L40).
- **Quale resolver viene scelto?** Leggere `page.type`, `page.template` e `page.pageId` dalla pagina CMS (`CmsService.getCurrentPage()`) e calcolare a mano lo score con la formula di core-libs/core/src/cms/page/page-meta.resolver.ts:L31-L45. In alternativa, mettere un breakpoint in `PageMetaService.getMetaResolver` (core-libs/core/src/cms/facade/page-meta.service.ts:L133-L139) e ispezionare l'array `resolvers`.
- **Un resolver registrato in un modulo lazy non viene usato.** `getMulti` legge gli injector dei moduli lazy solo dopo il caricamento (core-libs/core/src/lazy-loading/unified-injector.ts:L32-L35). Se la pagina viene visualizzata prima che la feature sia caricata, il resolver non c'è ancora.
- **Canonical inatteso.** Chiamare `PageLinkService.getCanonicalUrl()` dalla console tramite un componente di debug e confrontare l'URL grezzo (`location.href`) con le opzioni effettive (core-libs/core/src/cms/page/routing/page-link.service.ts:L33-L43). In SSR, se compare l'errore `Cannot resolve the href as the SERVER_REQUEST_URL is undefined`, il server non ha fornito il token (core-libs/core/src/window/window-ref.ts:L74-L78).

- **Il JSON-LD non compare.** Nell'ordine: (a) è importato `JsonLdBuilderModule`? (b) si sta guardando l'HTML SSR (view-source) e non il DOM CSR? (c) in dev, `seo.structuredData.disableInDevMode` è `false`? Il punto di controllo è `StructuredDataFactory.build` (core-libs/storefront/cms-structure/seo/structured-data/structured-data.factory.ts:L34-L42). Lo script cercato è `#json-ld` in fondo al `body` (core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L62-L76).
- **Hydration e JSON-LD.** DA VERIFICARE se lo `<script id="json-ld">` generato in SSR, che è appeso al `body` fuori dall'app root, resta nel DOM dopo l'idratazione client: non è stato confermato a runtime.
- **Service worker non registrato.** Controllare `isDevMode()` e `pwa.enabled` (core-libs/storefront/cms-structure/pwa/pwa.module.ts:L19-L23), la presenza di `ngsw-worker.js` nell'output della build (projects/storefrontapp/project.json:L169-L169) e il pannello Application → Service Workers del browser. Ricordare che la registrazione di default avviene quando l'app è stabile o dopo 30 secondi (angular:packages/service-worker/src/provider.ts:L69-L73).
- **Il banner A2HS non appare.** Il banner dipende da `beforeinstallprompt`, che emette il browser. Servono `pwa.addToHomeScreen: true` (core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L31-L33) e i criteri di installabilità del browser (manifest, HTTPS, service worker). Per testare la UI si può chiamare `AddToHomeScreenService.enableAddToHomeScreen()` (core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L59-L61). Il prompt reale però non parte senza `deferredEvent` (core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L67-L71).
- `<html lang>` **sbagliato.** Il valore è la lingua attiva con `_` → `-` (core-libs/storefront/cms-structure/seo/html-lang-provider.ts:L24-L27). Verificare la lingua attiva del site context (vedi 13 — Site context e theme).

---

11. Domande di autoverifica

1. **Su una pagina** `CONTENT_PAGE` **con template** `SearchResultsListPageTemplate` **e query param** `couponcode=ABC`**, quale resolver viene scelto e con che score?** `CouponSearchPageResolver` con score 3: +1 type, +1 template, +1 coupon. La ricerca ha 2 e il content resolver 1 (core-libs/core/src/cms/page/page-meta.resolver.ts:L31-L45, core-libs/core/src/product/services/coupon-search-page-meta.resolver.ts:L89-L91).
2. **Due resolver hanno lo stesso score: quale vince?** Quello fornito per ultimo, perché `resolveApplicable` sostituisce l'accumulatore anche a parità (`lastPriority > currPriority` è stretto) (core-libs/core/src/util/applicable.ts:L81-L85).
3. **Perché** `BasePageMetaResolver` **non viene mai selezionato da** `PageMetaService`**?** Perché non estende `PageMetaResolver` e non è multi-provided su quel token: è un servizio root usato per delega (core-libs/core/src/cms/page/base-page-meta.resolver.ts:L25-L42, core-libs/core/src/cms/page/page-meta.module.ts:L13-L21).
4. **Come si aggiunge una nuova proprietà al** `PageMeta` **calcolato?** Si aggiunge `{property, method}` a `pageMeta.resolvers` e si implementa `method` sul resolver. La config custom deve ripetere anche le voci di default, perché `deepMerge` sostituisce gli array (core-libs/core/src/config/utils/deep-merge.ts:L38-L45). `resolve()` invoca solo i metodi esistenti sull'istanza scelta (core-libs/core/src/cms/page/config/page-meta.config.ts:L22-L41, core-libs/core/src/cms/facade/page-meta.service.ts:L84-L103). Per scriverla nel DOM serve anche un `SeoMetaService` custom, perché il setter `meta` gestisce solo cinque proprietà (core-libs/storefront/cms-structure/seo/seo-meta.service.ts:L39-L45).
5. **Con la config di default, cosa diventa** `http://shop.com/p/123?utm=x`**?** `https://shop.com/p/123/`: forceHttps, nessun www, query rimossa, slash finale aggiunta (core-libs/core/src/cms/page/config/

default-page-meta.config.ts:L41-L46, core-libs/core/src/cms/page/routing/page-link.service.ts:L57-L79).

6. **Perché il canonical di una variante di prodotto punta al prodotto base?** `resolveCanonicalUrl` della PDP risale ricorsivamente `baseProduct` e costruisce l'URL della route `product` con quel prodotto (core-libs/core/src/product/services/product-page-meta.resolver.ts:L180-L209).
7. **In quali condizioni viene generato lo script JSON-LD?** Quando `isJsonLdRequired()` è vero (server, oppure dev mode con `disableInDevMode` non true) **e** sono registrati degli `SCHEMA_BUILDER`, cioè c'è `JsonLdBuilderModule` o un builder custom (core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L46-L51, core-libs/storefront/cms-structure/seo/structured-data/structured-data.factory.ts:L34-L42).
8. **Come si evita che contenuti del prodotto iniettino HTML nello script JSON-LD?** `escapeHtml` serializza con `JSON.stringify`, assegna la stringa a `textContent` di un `div` e legge `innerHTML`, così i caratteri HTML vengono escapati (core-libs/storefront/cms-structure/seo/structured-data/json-ld-script.factory.ts:L78-L88).
9. **Con** `pwa.enabled: true` **e** `ng serve`**, il service worker si registra?** No. `pwaConfigurationFactory` richiede `!isDevMode()` (core-libs/storefront/cms-structure/pwa/pwa.module.ts:L19-L23), e `ngswAppInitializer` esce quando `enabled === false` (angular:packages/service-worker/src/provider.ts:L32-L41).
10. **Perché** `AddToHomeScreenService` **viene istanziato all'avvio anche se nessun componente lo usa?** Perché `PwaModule` registra l'`APP_INITIALIZER` `pwaFactory` con `deps: [AddToHomeScreenService]`, e il costruttore del servizio chiama `init()` se `pwa.addToHomeScreen` è true (core-libs/storefront/cms-structure/pwa/pwa.module.ts:L47-L52, core-libs/storefront/cms-structure/pwa/services/add-to-home-screen.service.ts:L26-L34).

TAVOLA 40.1 **4.1 Dal cambio pagina CMS ai tag in <head>**

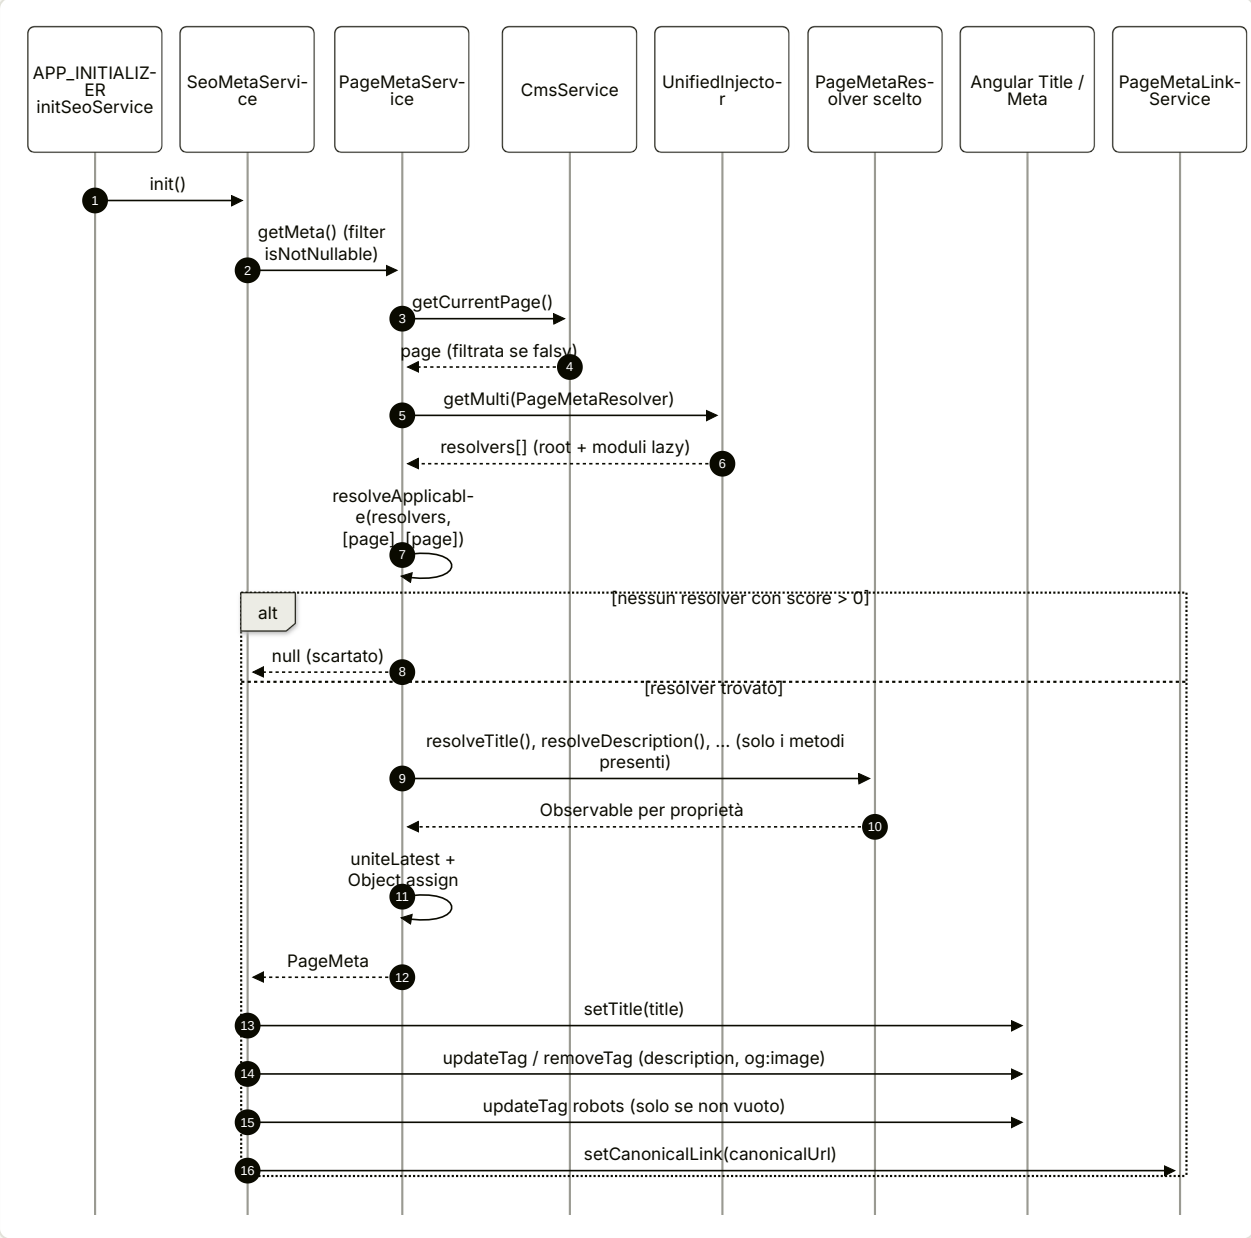

TAVOLA 40.2 **4.3 Calcolo del canonical URL**

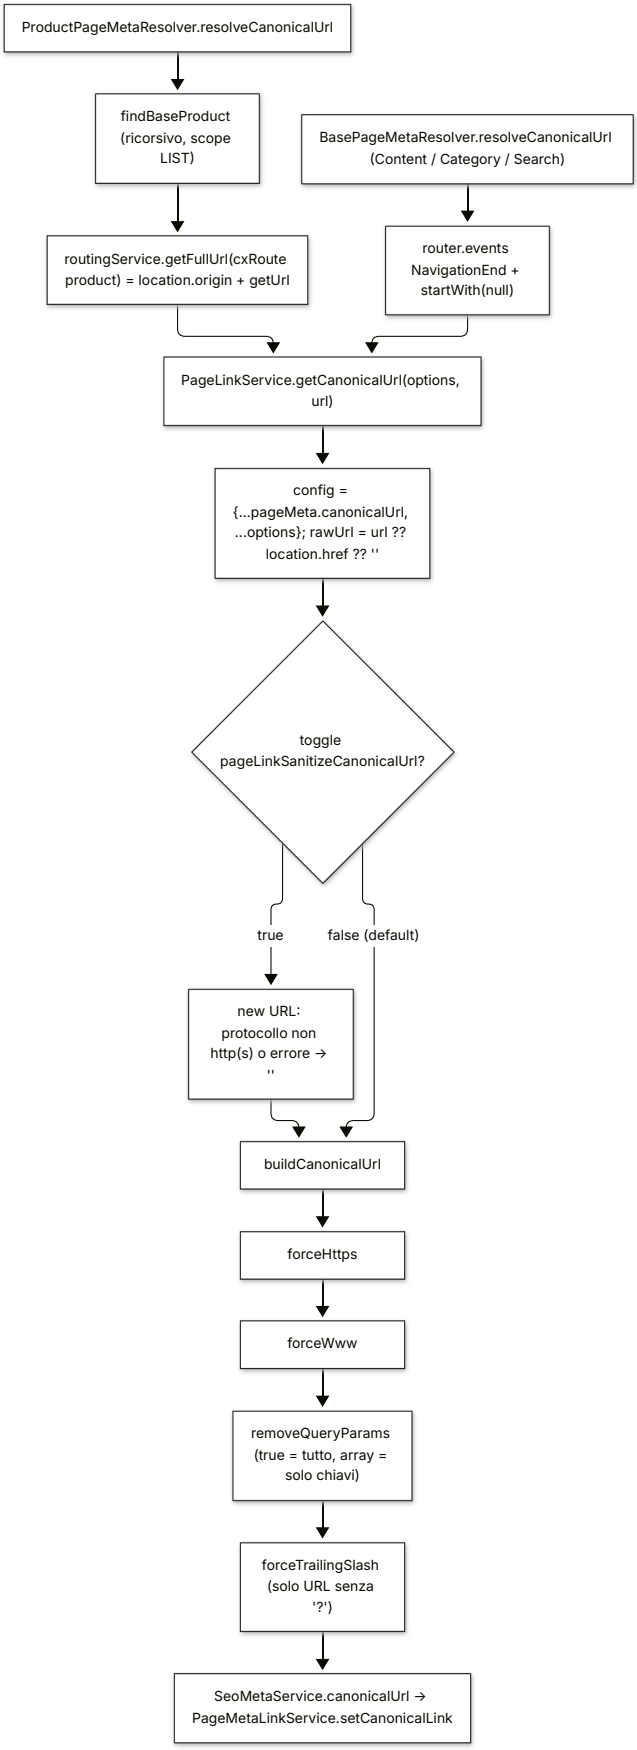

TAVOLA 40.3 **4.4 JSON-LD in SSR**

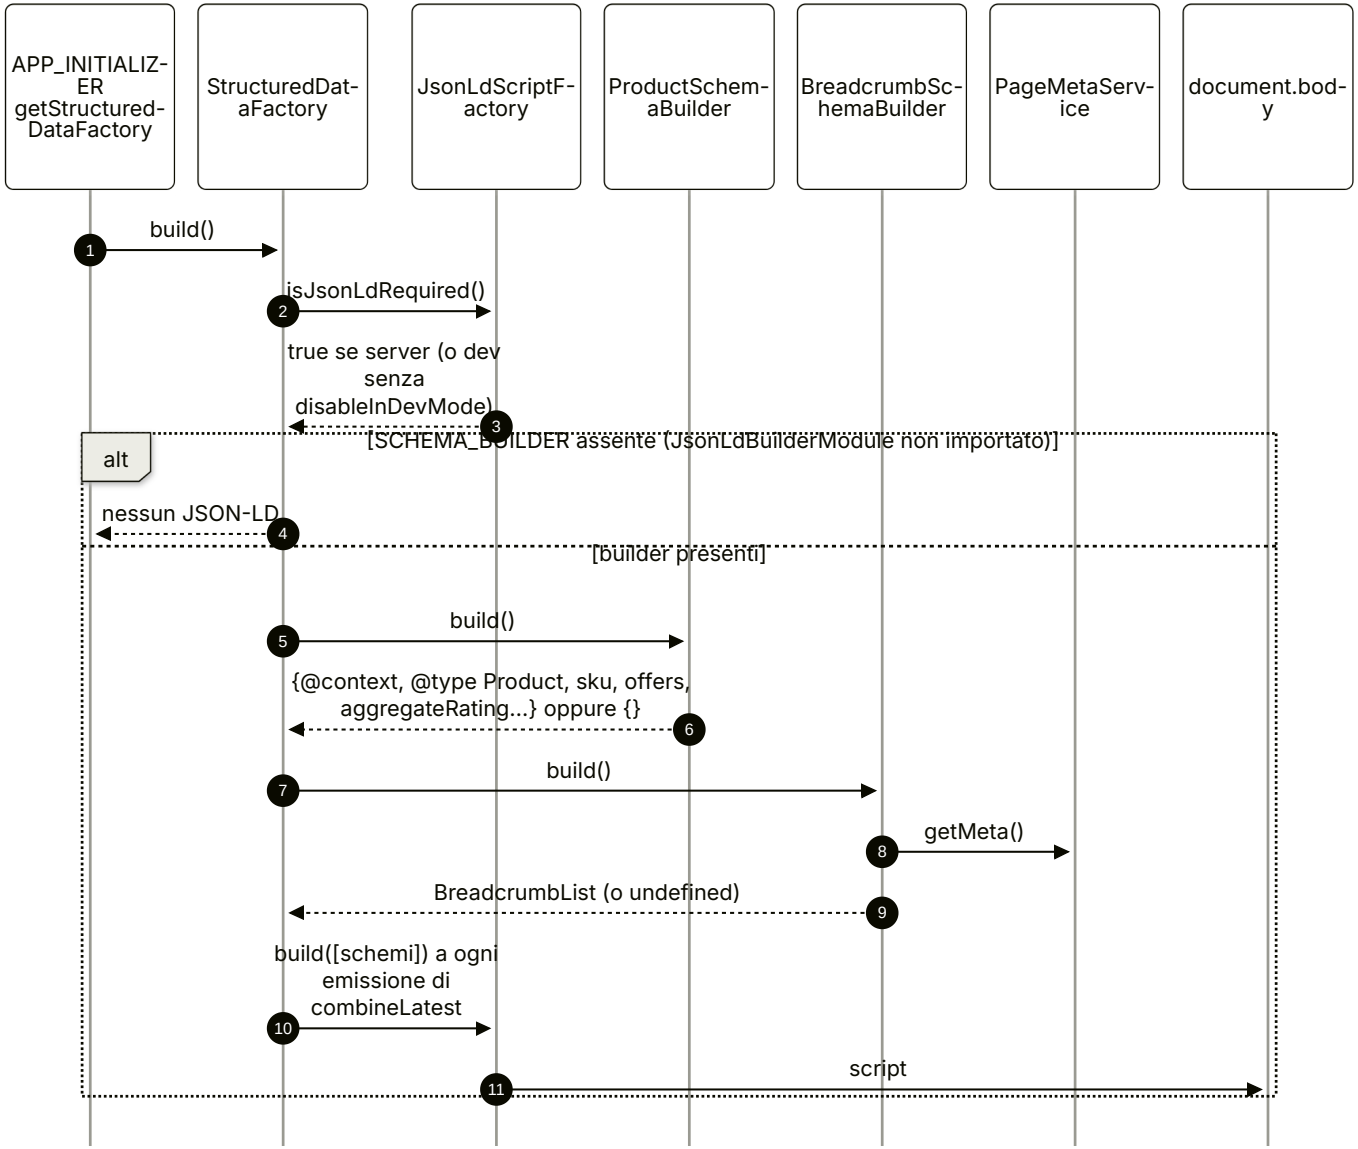

TAVOLA 40.4 **4.5 PWA: service worker e Add to Home Screen**

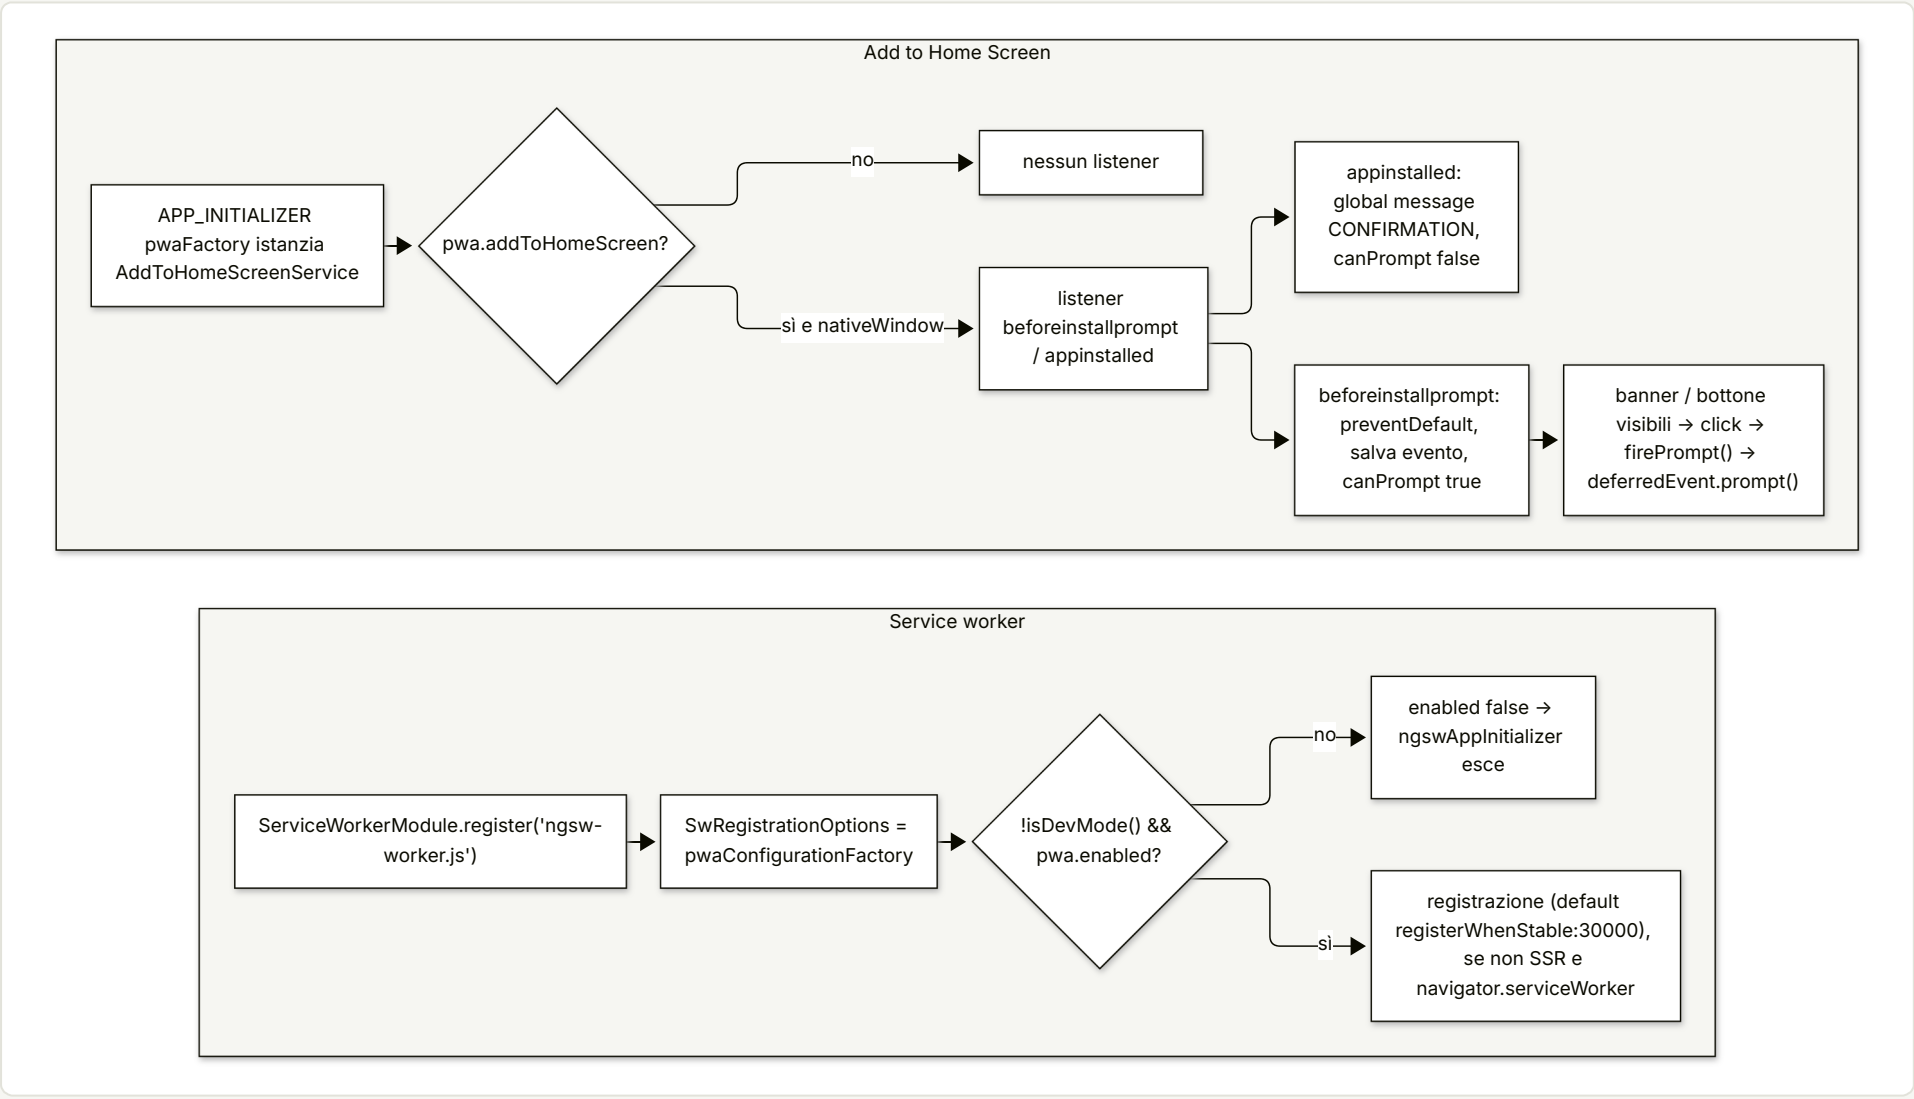

41

Errori HTTP, error handling, logger e global message

Due sottosistemi distinti: global message (UX) e error handling (osservabilità/SSR).

1. A cosa serve e perché esiste

Quando una chiamata OCC fallisce, in Spartacus succedono **due cose indipendenti**, gestite da due sottosistemi diversi che è facile confondere perché hanno nomi quasi identici:

SOTTOSISTEMA	CLASSE CHIAVE	DOMANDA A CUI RISPONDE	DOVE AGISCE
Global message (UX)	`HttpErrorInterceptor` + `HttpErrorHandler` (uno per status)	"Che messaggio mostro all'utente?"	browser e server (ma i messaggi hanno senso nel browser)
Error handling (osservabilità / SSR)	`HttpErrorHandlerInterceptor` + `CxErrorHandler` + `MULTI_ERROR_HANDLER`	"Chi deve sapere che c'è stato un errore? Devo far fallire il rendering SSR?"	inoltro di errori HTTP e fail action: solo in SSR (core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L72-L74). `CxErrorHandler` è comunque attivo anche nel browser (errori di componenti ed effect — deps:ngrx-effects-21.0.1/package/fesm2022/ngrx-effects.mjs:L176-L178 —, listener globali — projects/storefrontapp/src/app/app.config.ts:L31-L31)

Il primo sottosistema vive in `core-libs/core/src/global-message/`: un interceptor HTTP sceglie **un solo** handler applicabile per lo status della risposta (core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L45-L65) e l'handler, di norma, aggiunge una chiave di traduzione allo store NgRx `global-message` tramite `GlobalMessageService.add` (core-libs/core/src/global-message/facade/global-message.service.ts:L43-L55). Il componente `cx-global-message` legge lo store e mostra gli alert (core-libs/storefront/cms-components/misc/global-message/global-message.component.ts:L44-L50); un effect li rimuove dopo un timeout configurabile (core-libs/core/src/global-message/store/effects/global-message.effect.ts:L70-L106).

Il secondo sottosistema vive in `core-libs/core/src/error-handling/`: sostituisce l'`ErrorHandler` di Angular con `CxErrorHandler` (core-libs/core/src/error-handling/error-handling.module.ts:L20-L31), che fa da *fan-out* verso un array di `MultiErrorHandler` (core-libs/core/src/error-handling/cx-error-handler.ts:L26-L30). Due "sorgenti" alimentano l'`ErrorHandler`:

- gli errori HTTP, tramite `HttpErrorHandlerInterceptor`, che li incapsula in `OutboundHttpError` / `CmsPageNotFoundOutboundHttpError` (core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L76-L81);
- le *fail action* NgRx che portano una proprietà `error`, tramite `CxErrorHandlerEffect` ed `ErrorActionService` (core-libs/core/src/error-handling/effects-error-handler/cx-error-handler.effect.ts:L23-L32, core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L24-L37).

Entrambe le sorgenti, però, inoltrano solo quando **non** sono nel browser (`!windowRef.isBrowser()`): il motivo dichiarato è non esporre nella console del browser dati potenzialmente confidenziali, mentre in SSR si vuole catturare tutto per poter rispondere con un 404/500 (core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L63-L74). In SSR `provideServer()` aggiunge infatti un secondo multi handler che propaga l'errore al server Express (core-libs/setup/ssr/providers/ssr-providers.ts:L37-L45), dove `defaultExpressErrorHandlers` sceglie 404 o 500 (core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32).

Trasversale a tutto c'è `LoggerService`: un servizio `providedIn: 'root'` che delega al `console` ed è pensato come extension point per redirigere i log (core-libs/core/src/logger/logger.service.ts:L9-L22). L'unico multi error handler di default, `LoggingErrorHandler`, scrive proprio lì (core-libs/core/src/error-handling/multi-error-handler/logging-error-handler.ts:L17-L26), e in SSR il logger è sostituito da una versione server (core-libs/setup/ssr/logger/services/server-logger-service-factory.ts:L12-L17).

Questo capitolo si concentra su `@spartacus/core`. La parte Express/SSR (dove viene fornito `PROPAGATE_ERROR_TO_SERVER`, formato dei log server) è trattata in 39 — SSR ottimizzato; la catena di interceptor di Angular in 06 — HttpClient e interceptor.

2. Mappa dei file

PATH	RUOLO
core-libs/core/src/error-handling/error-handling.module.ts	`ErrorHandlingModule`: importa effects/http error handler; `forRoot()` sostituisce `ErrorHandler` con `CxErrorHandler` e registra `LoggingErrorHandler`
core-libs/core/src/error-handling/cx-error-handler.ts	`CxErrorHandler`: fan-out su `MULTI_ERROR_HANDLER`
core-libs/core/src/error-handling/multi-error-handler/multi-error-handler.ts	interfaccia `MultiErrorHandler`, token `MULTI_ERROR_HANDLER`
core-libs/core/src/error-handling/multi-error-handler/logging-error-handler.ts	`LoggingErrorHandler` → `LoggerService.error`
core-libs/core/src/error-handling/multi-error-handler/provide-multi-error-handler.ts	`provideMultiErrorHandler()` (non esportato dal barrel)
core-libs/core/src/error-handling/multi-error-handler/index.ts	barrel
core-libs/core/src/error-handling/http-error-handler/http-error-handler.module.ts	`HttpErrorHandlerModule.forRoot()`: registra l'interceptor
core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts	`HttpErrorHandlerInterceptor`: errori HTTP → `ErrorHandler` (solo SSR)
core-libs/core/src/error-handling/http-error-handler/outbound-http-error.ts	`OutboundHttpError`, `CmsPageNotFoundOutboundHttpError`
core-libs/core/src/error-handling/http-error-handler/index.ts	barrel
core-libs/core/src/error-handling/effects-error-handler/effects-error-handler.module.ts	`EffectsErrorHandlerModule`: effect + `ErrorActionService`
core-libs/core/src/error-handling/effects-error-handler/cx-error-handler.effect.ts	`CxErrorHandlerEffect` (non esportato)
core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts	`ErrorActionService`: filtro action d'errore, esclusione errori HTTP
core-libs/core/src/error-handling/effects-error-handler/error-action.ts	interfaccia `ErrorAction`
core-libs/core/src/error-handling/effects-error-handler/index.ts	barrel

PATH	RUOLO
core-libs/core/src/error-handling/index.ts	barrel dell'area
core-libs/core/src/global-message/global-message.module.ts	`GlobalMessageModule`: store, effect, default config; `forRoot()` aggiunge handler + interceptor
core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts	`HttpErrorInterceptor`: sceglie l'`HttpErrorHandler` applicabile (non esportato)
core-libs/core/src/global-message/http-interceptors/index.ts	array `errorHandlers` e `httpErrorInterceptors`
core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts	classe astratta `HttpErrorHandler` (`Applicable`)
core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts	400: password, login, validation, duplicate uid, unknown identifier, illegal argument
core-libs/core/src/global-message/http-interceptors/handlers/forbidden/forbidden.handler.ts	403: messaggio + `logout()` se `users/current`
core-libs/core/src/global-message/http-interceptors/handlers/not-found/not-found.handler.ts	404: no-op intenzionale
core-libs/core/src/global-message/http-interceptors/handlers/conflict/conflict.handler.ts	409
core-libs/core/src/global-message/http-interceptors/handlers/internal-server/internal-server.handler.ts	500
core-libs/core/src/global-message/http-interceptors/handlers/bad-gateway/bad-gateway.handler.ts	502
core-libs/core/src/global-message/http-interceptors/handlers/gateway/gateway-timeout.handler.ts	504
core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts	fallback: `warn` solo in dev mode
core-libs/core/src/global-message/http-interceptors/handlers/index.ts	barrel degli handler
core-libs/core/src/global-message/models/global-message.model.ts	`GlobalMessageType`, `GlobalMessage`
core-libs/core/src/global-message/models/response-status.model.ts	`HttpResponseStatus`
core-libs/core/src/global-message/facade/global-message.service.ts	`GlobalMessageService` (`get`/`add`/`remove`)
core-libs/core/src/global-message/config/global-message-config.ts	`GlobalMessageConfig`, `GlobalMessageTypeConfig`, augmentation di `Config`
core-libs/core/src/global-message/config/default-global-message-config.ts	`defaultGlobalMessageConfig` (non pubblico)

PATH	RUOLO
core-libs/core/src/global-message/store/global-message-state.ts	GLOBAL_MESSAGE_FEATURE, interfacce di stato
core-libs/core/src/global-message/store/global-message-store.module.ts	GlobalMessageStoreModule
core-libs/core/src/global-message/store/actions/global-message.actions.ts	AddMessage, RemoveMessage, RemoveMessagesByType
core-libs/core/src/global-message/store/reducers/global-message.reducer.ts	reducer, initialState
core-libs/core/src/global-message/store/reducers/index.ts	reducerToken, reducerProvider, getReducers
core-libs/core/src/global-message/store/selectors/global-message.selectors.ts	entities / byType / countByType
core-libs/core/src/global-message/store/effects/global-message.effect.ts	GlobalMessageEffect: dedup + auto-hide
core-libs/core/src/global-message/index.ts	barrel pubblico dell'area
core-libs/core/src/logger/logger.service.ts	LoggerService
core-libs/core/src/logger/testing/mock-logger.service.ts	MockLoggerService silenzioso
core-libs/core/src/logger/testing/logger-testing.module.ts	LoggerTestingModule
core-libs/core/src/util/applicable.ts	Applicable, Priority, resolveApplicable (fuori area, ma decisivo)
core-libs/core/src/util/try-normalize-http-error.ts	tryNormalizeHttpError → HttpErrorModel
core-libs/storefront/cms-components/misc/global-message/global-message.component.ts	GlobalMessageComponent (cx-global-message)
core-libs/setup/ssr/providers/ssr-providers.ts	provideServer(): logger server + PropagatingToServerErrorHandler
core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts	defaultExpressErrorHandlers: 404/500 + fallback CSR

3. Come funziona passo per passo

3.1 Bootstrap: chi registra cosa, e in che ordine

1. BaseStorefrontModule importa BaseCoreModule.forRoot() e GlobalMessageComponentModule — core-libs/storefront/base-storefront.module.ts:L26-L30.
2. BaseCoreModule importa **per primo** ErrorHandlingModule.forRoot(), con il commento "Import this module before any other interceptor to handle HTTP errors efficiently" — core-libs/core/src/base-core.module.ts:L26-L29.
3. ErrorHandlingModule importa EffectsErrorHandlerModule.forRoot() e HttpErrorHandlerModule.forRoot() — core-libs/core/src/error-handling/error-handling.module.ts:L13-L18. Il secondo registra HttpErrorHandlerInterceptor in HTTP_INTERCEPTORS (useExisting, multi) — core-libs/core/src/

error-handling/http-error-handler/http-error-handler.module.ts:L11-L24. Essendo il primo interceptor registrato, è il più **esterno** della catena.

4. `ErrorHandlingModule.forRoot()` aggiunge `provideMultiErrorHandler()` (→ `MULTI_ERROR_HANDLER = LoggingErrorHandler`) e `{ provide: ErrorHandler, useClass: CxErrorHandler }` — core-libs/core/src/error-handling/error-handling.module.ts:L20-L31, core-libs/core/src/error-handling/multi-error-handler/provide-multi-error-handler.ts:L11-L19.
5. `EffectsErrorHandlerModule` registra `CxErrorHandlerEffect` via `EffectsModule.forFeature` e, nel `forRoot()`, fornisce `ErrorActionService` — core-libs/core/src/error-handling/effects-error-handler/effects-error-handler.module.ts:L12-L22.
6. Più avanti `BaseCoreModule` importa `GlobalMessageModule.forRoot()` (dopo `CmsModule.forRoot()`, prima di `HttpModule.forRoot()`) — core-libs/core/src/base-core.module.ts:L34-L42.
7. `GlobalMessageModule` importa lo store e l'effect e fornisce `provideDefaultConfig(defaultGlobalMessageConfig)` — core-libs/core/src/global-message/global-message.module.ts:L19-L25; `forRoot()` aggiunge `...errorHandlers, ...httpErrorInterceptors` — core-libs/core/src/global-message/global-message.module.ts:L26-L32.
8. `errorHandlers` registra 8 handler come multi-provider del token-classe `HttpErrorHandler` con `useExisting`: Unknown, BadGateway, BadRequest, Conflict, Forbidden, GatewayTimeout, InternalServerError, NotFound — core-libs/core/src/global-message/http-interceptors/index.ts:L22-L63. `httpErrorInterceptors` registra `HttpErrorInterceptor` — core-libs/core/src/global-message/http-interceptors/index.ts:L65-L71.
9. `HttpModule.forRoot()` porta `HttpTimeoutInterceptor`, registrato dopo e quindi più interno — core-libs/core/src/base-core.module.ts:L42-L42, core-libs/core/src/http/http-timeout/http-timeout.module.ts:L13-L23.
10. Nell'app demo, `BaseStorefrontModule` precede `SpartacusFeaturesModule` (che contiene `AuthModule.forRoot()`), quindi gli interceptor di autenticazione sono ancora più interni — projects/storefrontapp/src/app/spartacus/spartacus.module.ts:L14-L15, projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L179-L179.
11. Angular compone `HTTP_INTERCEPTORS` con `reduceRight`: dato `[a, b, c]` costruisce `c(b(a(end)))`, cioè il primo registrato vede la richiesta per primo e l'errore **per ultimo** — angular:packages/common/http/src/interceptor.ts:L232-L240.
12. In SSR, `provideServer()` (usato dall'`AppServerModule` della demo, projects/storefrontapp/src/app/app.module.server.ts:L10-L17) sostituisce `LoggerService` con `serverLoggerServiceFactory` e aggiunge `PropagatingToServerErrorHandler` come secondo `MULTI_ERROR_HANDLER` — core-libs/setup/ssr/providers/ssr-providers.ts:L27-L46.

Il risultato, per una richiesta OCC nella demo, è una catena (dall'esterno all'interno): `HttpErrorHandlerInterceptor` → … → `HttpErrorInterceptor` → … → `HttpTimeoutInterceptor` → … → interceptor auth → backend.

> DA VERIFICARE — L'ordine effettivo degli interceptor intermedi (site context, consensi, ecc.) dipende dall'ordine degli import dell'applicazione; qui è verificato solo l'ordine relativo dei quattro citati e solo per `projects/storefrontapp` (dossier Q4). Nella demo `AppModule` (e quindi tutta la catena) è caricato con `importProvidersFrom(AppModule)` e non ci sono altri `HTTP_INTERCEPTORS` registrati prima — projects/storefrontapp/src/app/app.config.ts:L26-L35.

3.2 Il ramo "global message": dall'`HttpErrorResponse` all'alert

1. La risposta d'errore risale la catena dall'interno verso l'esterno — angular:packages/common/http/src/interceptor.ts:L232-L240.

2. `HttpErrorInterceptor.intercept` aggancia un `tap({ error })`: l'errore **non** viene catturato né sostituito, continua a propagarsi al chiamante. Reagisce solo se l'errore è `instanceof HttpErrorResponse` — core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L30-L43.
3. L'Observable degli handler è creato alla costruzione dell'interceptor con `UnifiedInjector.getMulti(HttpErrorHandler)` più `shareReplay(1)` — core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L22-L28. Viene sottoscritto al primo errore e da allora resta attivo (`shareReplay` senza `refCount`), accumulando anche gli handler dei moduli lazy caricati in seguito; i moduli già caricati sono riemessi perché `modules$` è un `ReplaySubject` connesso — core-libs/core/src/lazy-loading/lazy-modules.service.ts:L47-L55. `getMulti` interroga il root injector e gli injector dei moduli lazy, accumulando le istanze con `scan` — core-libs/core/src/lazy-loading/unified-injector.ts:L79-L93; `injectors$` parte con `startWith(this.rootInjector)` — core-libs/core/src/lazy-loading/unified-injector.ts:L32-L35. Per il funzionamento dell'`UnifiedInjector` vedi 12 — Feature module e lazy loading.
4. `getResponseHandler` legge **sincronamente** l'ultimo array con `getLastValueSync` (subscribe + unsubscribe immediato) e lo passa a `resolveApplicable(handlers, [response])` — core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L59-L65, core-libs/core/src/util/rxjs/get-last-value-sync.ts:L9-L23.
5. `resolveApplicable` tiene solo gli handler con `hasMatch(response) === true` (o senza `hasMatch`); se ne restano meno di due restituisce il primo — core-libs/core/src/util/applicable.ts:L63-L74. Altrimenti vince la priorità più alta; a parità vince quello registrato **più tardi**; senza `getPriority` vale `Priority.NORMAL` — core-libs/core/src/util/applicable.ts:L76-L86, regola documentata nel JSDoc core-libs/core/src/util/applicable.ts:L54-L57.
6. L'`hasMatch` di default di `HttpErrorHandler` confronta `errorResponse.status === this.responseStatus` — core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts:L42-L44. `UnknownErrorHandler` sovrascrive `hasMatch` restituendo sempre `true` e ha `Priority.FALLBACK` (−50) — core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L22-L50. Tutti gli altri handler di default hanno `Priority.LOW` (−10) — es. core-libs/core/src/global-message/http-interceptors/handlers/forbidden/forbidden.handler.ts:L39-L41. Valori di `Priority`: core-libs/core/src/util/applicable.ts:L7-L24.
7. Viene invocato **un solo** handler: `handler.handleError(request, response)` — core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L45-L53.
8. L'handler, tipicamente, chiama `globalMessageService.add({ key: 'httpHandlers.xxx' }, GlobalMessageType.MSG_TYPE_ERROR)` — es. core-libs/core/src/global-message/http-interceptors/handlers/internal-server/internal-server.handler.ts:L16-L28. Le traduzioni inglesi stanno sotto `httpHandlers` in core-libs/assets/src/translations/en/common.json:L116-L172 (vedi 37 — i18n).
9. `GlobalMessageService.add` dispatcha `AddMessage`, avvolgendo una stringa in `{ raw: text }` — core-libs/core/src/global-message/facade/global-message.service.ts:L43-L55.
10. Il reducer accoda `message.text` all'array del tipo (creandolo se manca); `timeout` **non** viene salvato nello stato — core-libs/core/src/global-message/store/reducers/global-message.reducer.ts:L24-L45.
11. `GlobalMessageEffect.removeDuplicated$`: se dopo l'aggiunta esistono più testi deep-equal, dispatcha `RemoveMessage` sull'indice della **prima** occorrenza — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L31-L68, utilità di confronto in core-libs/core/src/util/object-comparison-utils.ts:L77-L92.
12. `GlobalMessageEffect.hideAfterDelay$` (solo browser) attende `message.timeout || config.timeout` e poi rimuove l'indice `0` del tipo — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L73-L101.
13. `GlobalMessageComponent` sottoscrive `globalMessageService.get()` e rende gli alert; la X chiama `remove(type, index)` — core-libs/storefront/cms-components/misc/global-message/global-message.

component.ts:L44-L50, template core-libs/storefront/cms-components/misc/global-message/global-message.component.html:L25-L94.

3.3 Il ramo "error handling": dall'errore HTTP all'`ErrorHandler`

1. `HttpErrorHandlerInterceptor` (il più esterno) usa anch'esso `tap({ error })` e osserva **qualsiasi** errore, non solo `HttpErrorResponse` (anche ad es. un `TimeoutError` RxJS lanciato da un interceptor successivo, come nota il JSDoc) — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L48-L61, core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L34-L35.
2. `shouldHandleError` restituisce `!this.windowRef.isBrowser()`: **nel browser si ferma qui** — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L63-L74.
3. In SSR, `handleError` avvolge l'errore in `CmsPageNotFoundOutboundHttpError` se è un 404 sull'endpoint OCC `pages`, altrimenti in `OutboundHttpError`, e chiama `errorHandler.handleError` — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L76-L81.
4. Il test "CMS page not found" costruisce l'URL atteso con `occEndpointsService.buildUrl('pages', { urlParams: { userId } })` (userId letto da un signal ottenuto con `toSignal(UserIdService.getUserId())`) e verifica `HttpErrorResponse`, status 404 e `url.startsWith(expectedUrl)` — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L46-L46, core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L89-L98.
5. `OutboundHttpError` estende `Error` con messaggio `'Outbound HTTP Error'` e conserva l'originale in `cause`; la sottoclasse sovrascrive `message` con `'CMS Page Not Found'` — core-libs/core/src/error-handling/http-error-handler/outbound-http-error.ts:L10-L25.
6. L'`ErrorHandler` iniettato è `CxErrorHandler`, che chiama `handleError(error)` su ogni elemento di `MULTI_ERROR_HANDLER`, nell'ordine di registrazione e senza `try/catch` — core-libs/core/src/error-handling/cx-error-handler.ts:L18-L30, core-libs/core/src/error-handling/multi-error-handler/multi-error-handler.ts:L20-L27.
7. `LoggingErrorHandler` → `this.logger.error(error)` — core-libs/core/src/error-handling/multi-error-handler/logging-error-handler.ts:L17-L26. In SSR il `LoggerService` è `ExpressLoggerService` se esiste il token `REQUEST`, altrimenti `PrerenderingLoggerService` — core-libs/setup/ssr/logger/services/server-logger-service-factory.ts:L12-L17.
8. `PropagatingToServerErrorHandler` chiama `PROPAGATE_ERROR_TO_SERVER(error)` (opzionale, fallback noop) — core-libs/setup/ssr/error-handling/multi-error-handlers/propagating-to-server-error-handler.ts:L29-L37.
9. Lato Express, `defaultExpressErrorHandlers` (solo se `!res.headersSent`) imposta `Cache-Control: no-store` e risponde 404 per `CmsPageNotFoundOutboundHttpError`, 500 altrimenti, inviando il documento come fallback CSR — core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32.

3.4 Il ramo "error handling" per le fail action NgRx

1. Un effect cattura un errore e dispatcha una fail action con proprietà `error`: lo fanno di serie `LoaderFailAction` ed `EntityFailAction`, che implementano `ErrorAction` — core-libs/core/src/state/utils/loader/loader.action.ts:L74-L83, core-libs/core/src/state/utils/entity-loader/entity-loader.action.ts:L80-L88; ed esempi "manuali" come `LoadDeliveryCountriesFail` — core-libs/core/src/user/store/actions/delivery-countries.action.ts:L25-L32. Per le action loader/entity vedi 19 — State management.

2. Gli errori HTTP sono di norma normalizzati con `tryNormalizeHttpError`, che converte `HttpErrorResponse` in `HttpErrorModel` (message, status, statusText, url, details) o restituisce l'errore così com'è — core-libs/core/src/util/try-normalize-http-error.ts:L21-L57.
3. `CxErrorHandlerEffect.error$` (`dispatch: false`) filtra con `errorActionService.isErrorAction` e chiama `errorActionService.handle` — core-libs/core/src/error-handling/effects-error-handler/cx-error-handler.effect.ts:L23-L32.
4. `isErrorAction` è semplicemente `'error' in action` — core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L39-L43.
5. `handle` scarta gli errori `HttpErrorModel` e `HttpErrorResponse` ("already handled in HttpErrorHandlerInterceptor") e inoltra gli altri all'`ErrorHandler` solo se `shouldHandleError`, che ancora una volta è `!windowRef.isBrowser()` — core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L24-L37, core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L54-L56.
6. Da qui il percorso è quello di 3.3 passi 6-9.

Nota: indipendentemente da Spartacus, NgRx stesso chiama `errorHandler.handleError(error)` quando un effect va in errore (non quando dispatcha una fail action) e lo risottoscrive fino a 10 volte — deps:ngrx-effects-21.0.1/package/fesm2022/ngrx-effects.mjs:L174-L185. Quel percorso arriva a `CxErrorHandler` **anche nel browser**, perché non passa da `shouldHandleError`.

3.5 L'`ErrorHandler` di Angular: cosa sostituisce Spartacus

L'`ErrorHandler` di default di Angular si limita a `console.error('ERROR', error)` — angular:packages/core/src/error_handler.ts:L54-L63. Angular lo risolve pigramente dall'`EnvironmentInjector` tramite `INTERNAL_APPLICATION_ERROR_HANDLER` e lo esegue fuori dalla zona — angular:packages/core/src/error_handler.ts:L68-L91. I listener globali `error`/`unhandledrejection` del browser (via `provideBrowserGlobalErrorListeners`) non sono attivi in server mode — angular:packages/core/src/error_handler.ts:L108-L124. Spartacus non cambia questo meccanismo: cambia solo *quale* classe risponde al token `ErrorHandler` (core-libs/core/src/error-handling/error-handling.module.ts:L25-L28). Il risultato pratico: nel browser, un errore non gestito di un componente arriva a `CxErrorHandler` → `LoggingErrorHandler` → `console.error` via `LoggerService`.

3.6 Timeout e errori di rete

1. `HttpTimeoutInterceptor` (interno) converte un `TimeoutError` RxJS in `HttpErrorResponse({ url, error })` senza status — core-libs/core/src/http/http-timeout/http-timeout.interceptor.ts:L101-L110; un `HttpErrorResponse` senza status vale `0` ("Unknown Error") — angular:packages/common/http/src/response.ts:L401-L421.
2. In `HttpErrorInterceptor` nessun handler ha `responseStatus` 0, quindi vince `UnknownErrorHandler`, che non aggiunge messaggi e fa solo `logger.warn` in `isDevMode()` — core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L30-L43.
3. In SSR `HttpErrorHandlerInterceptor` lo inoltra come `OutboundHttpError` → 500 — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L76-L81.

3.7 Il `BadRequestHandler` in dettaglio

Il 400 è lo status più "carico" di semantica OCC, perciò `BadRequestHandler` (priorità LOW) esegue **in sequenza** sei sotto-handler, ognuno dei quali filtra gli `ErrorModel` della risposta — core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L22-L33:

SOTTO-HANDLER	CONDIZIONE	MESSAGGIO	RIFERIMENTO
handleBadPassword	URL contiene / authorizationserver/oauth/token, error === 'invalid_grant', body grant_type === 'password'	chiave da getErrorTranslationKey(error_description), param errorMessage; poi remove(MSG_TYPE_CONFIRMATION)	core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L17-L17, core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L35-L67
handleBadLoginResponse	type === 'PasswordMismatchError'	path /password → httpHandlers.badRequestOldPasswordIncorrect, altrimenti httpHandlers.validationErrors.invalid.password	core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L73-L87
handleValidationError	type === 'ValidationError'	httpHandlers.validationErrors.<reason>.<subject>	core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L94-L103
handleGuestDuplicateEmail	type === 'DuplicateUidError'	httpHandlers.badRequestGuestDuplicateEmail con errorMessage	core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L124-L136
handleUnknownIdentifierError	type === 'UnknownIdentifierError'	error.message raw, altrimenti httpHandlers.unknownIdentifier	core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L143-L152
handleValidationErrorIleggalArgument	type === 'IllegalArgumentError'	error.message raw	core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L106-L118

getErrors legge response.error.errors (o []) escludendo JaloObjectNoLongerValidError — core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L155-L159. getErrorTranslationKey (definito nella classe base) converte la descrizione in httpHandlers.badRequest.<snake_case> o, se vuota, in httpHandlers.badRequestPleaseLoginAgain — core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts:L51-L59. Con il toggle enablePasswordExpiredErrorTranslation, una chiave che inizia con ...password_expired_for_the_user è rimappata su httpHandlers.badRequest.password_expired — core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L50-L57.

Le feature lib specializzano il 400 con handler a priorità più alta: ad esempio BadCartRequestHandler usa Priority.NORMAL e restringe hasMatch a super.hasMatch(...) && getErrors(...).some(isCartError) — feature-libs/cart/base/core/http-interceptors/handlers/bad-cart-request.handler.ts:L21-L33, registrato in CartBaseCoreModule — feature-libs/cart/base/core/cart-base-core.module.ts:L37-L46. Così un 400 "di carrello" va **solo** a BadCartRequestHandler, mentre un 400 generico continua ad andare a BadRequestHandler. Pattern analoghi in checkout B2B, quote, organization, pdf-invoices, configuratore, ticketing, requested delivery date (dossier F+2, es. feature-libs/quote/root/quote-root.module.ts:L110-L117).

3.8 Gli altri handler per status

STATUS	HANDLER	PRIORITÀ	EFFETTO	RIFERIMENTO
403	`ForbiddenHandler`	LOW	se `request.url` termina con l'URL OCC `user` per `current` → `authService.logout()`; sempre `httpHandlers.forbidden`	`core-libs/core/src/global-message/http-interceptors/handlers/forbidden/forbidden.handler.ts:L23-L37`
404	`NotFoundHandler`	LOW	nessuno (vuoto per non cadere nell'Unknown)	`core-libs/core/src/global-message/http-interceptors/handlers/not-found/not-found.handler.ts:L15-L24`
409	`ConflictHandler`	LOW	`httpHandlers.conflict`	`core-libs/core/src/global-message/http-interceptors/handlers/conflict/conflict.handler.ts:L16-L28`
500	`InternalServerErrorHandler`	LOW	`httpHandlers.internalServerError`	`core-libs/core/src/global-message/http-interceptors/handlers/internal-server/internal-server.handler.ts:L16-L28`
502	`BadGatewayHandler`	LOW	`httpHandlers.badGateway`	`core-libs/core/src/global-message/http-interceptors/handlers/bad-gateway/bad-gateway.handler.ts:L16-L28`
504	`GatewayTimeoutHandler`	LOW	`httpHandlers.gatewayTimeout`	`core-libs/core/src/global-message/http-interceptors/handlers/gateway/gateway-timeout.handler.ts:L16-L28`
qualsiasi	`UnknownErrorHandler`	FALLBACK	solo `warn` in dev mode	`core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L22-L50`

`HttpResponseStatus` include anche `UNAUTHORIZED = 401`, ma nessun handler di default lo usa — `core-libs/core/src/global-message/models/response-status.model.ts:L7-L17`, `core-libs/core/src/global-message/http-interceptors/index.ts:L22-L63`. Il 401 è normalmente assorbito dall'`AuthInterceptor` con refresh e retry (vedi 22 — Autenticazione).

4. Diagrammi

4.1 Registrazione e ordine della catena di interceptor

■ **TAVOLA 41.1** diagramma a tutta pagina, in fondo al capitolo

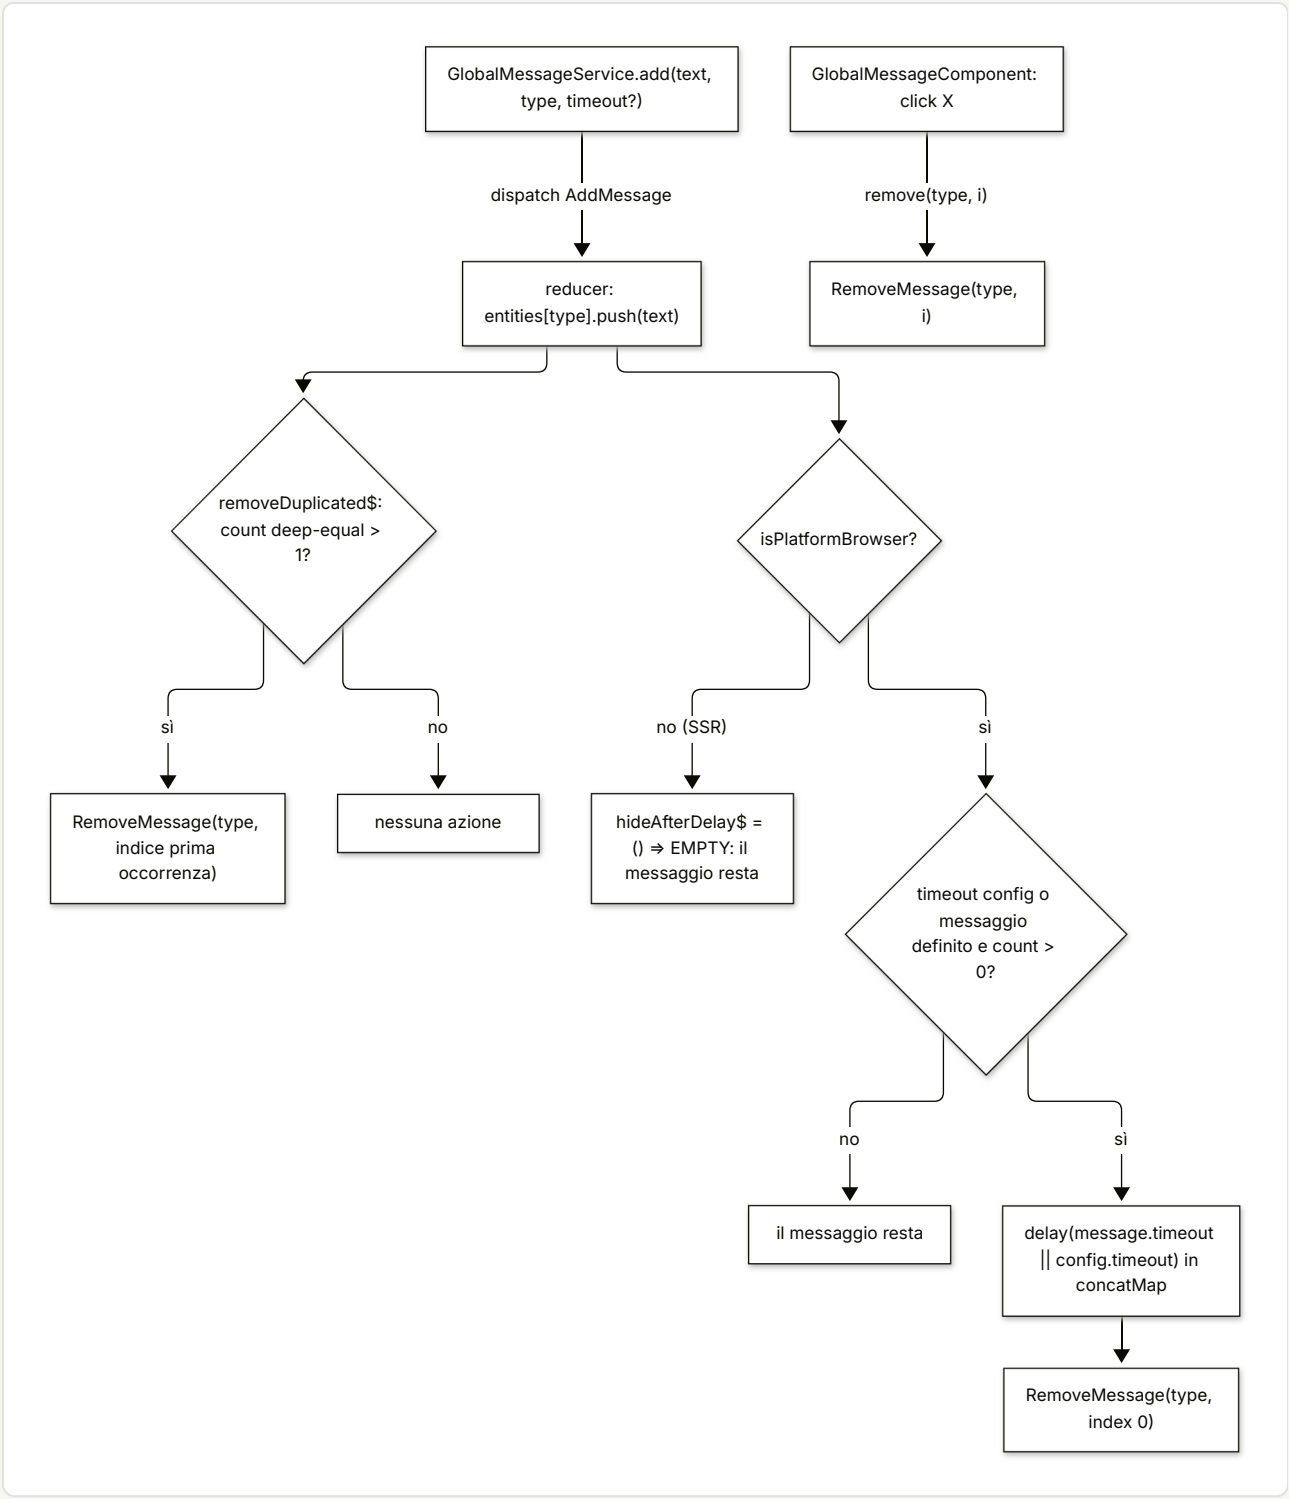
Ogni freccia corrisponde a un passo di §3.1 (passi 1-12). L'ordine di registrazione, per `reduceRight`, diventa ordine di annidamento: `HttpErrorHandlerInterceptor` è il più esterno, gli interceptor auth i più interni (`angular:packages/common/http/src/interceptor.ts:L232-L240`).

4.2 Un errore 500 che risale la catena: browser vs SSR

■ **TAVOLA 41.2** diagramma a tutta pagina, in fondo al capitolo

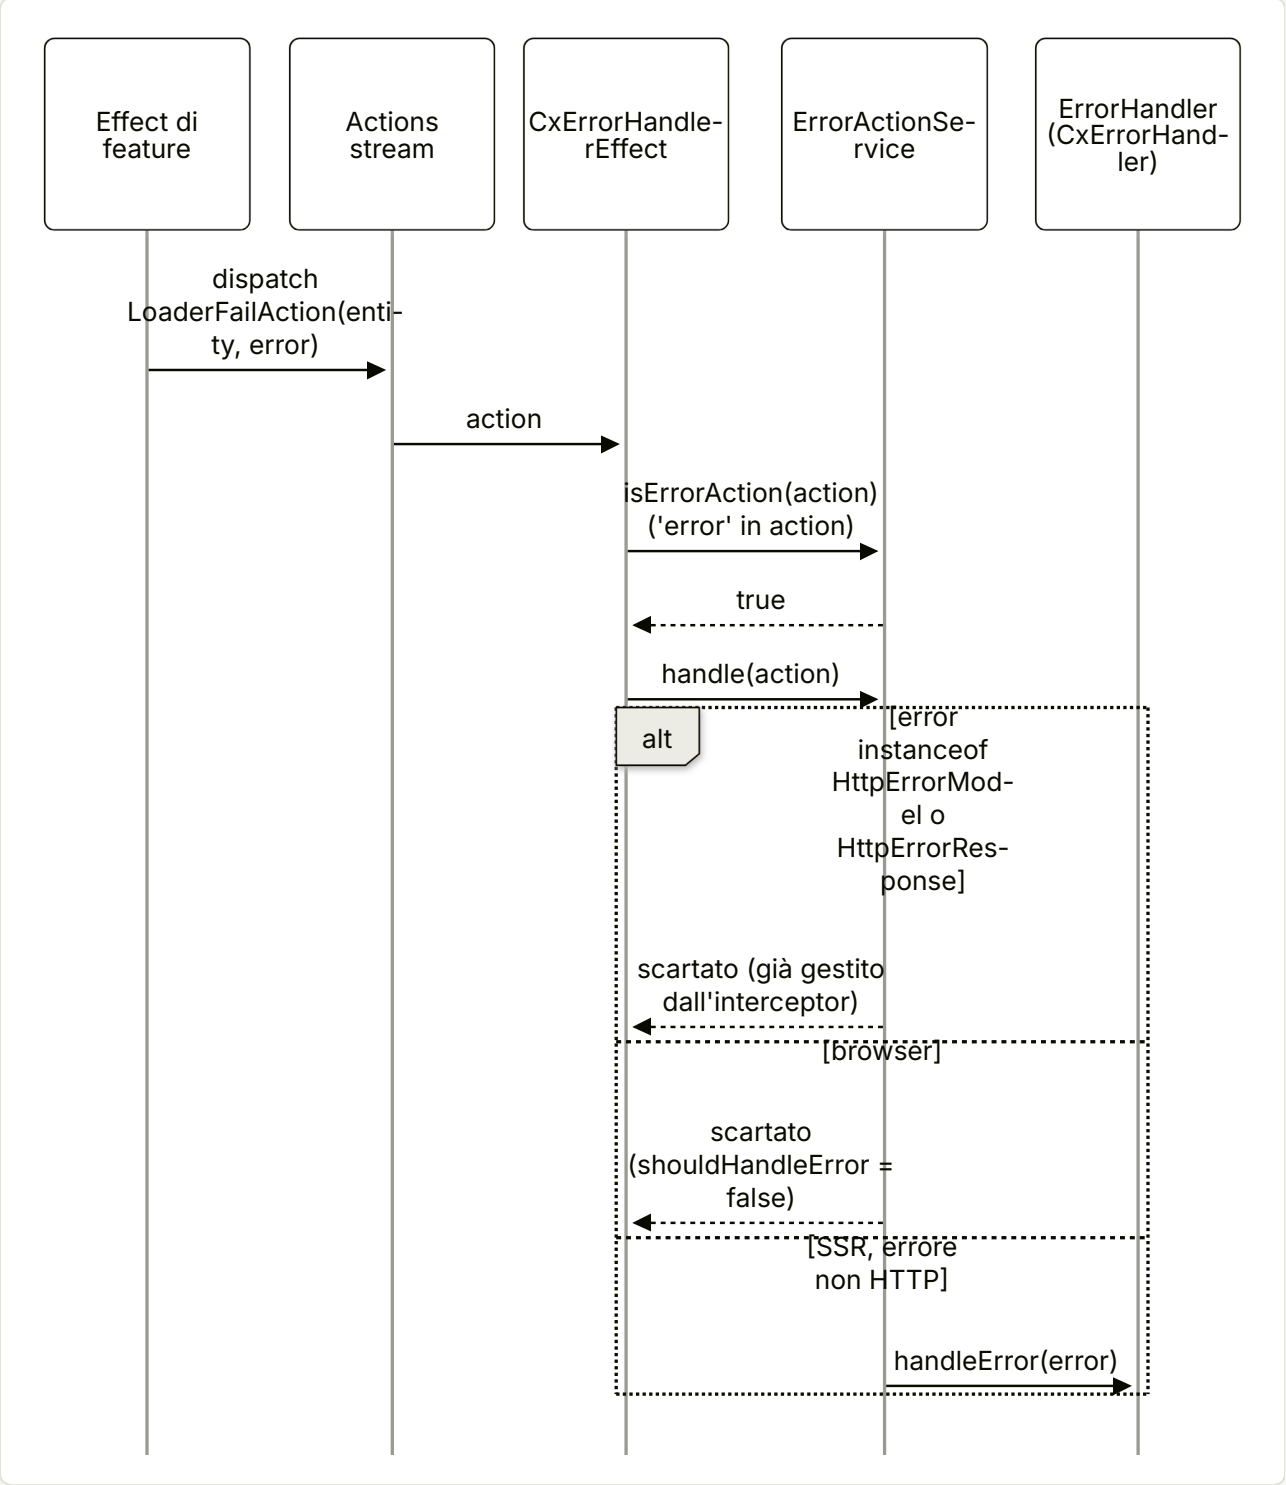
Riferimenti: §3.2 passi 2-9 e §3.3 passi 1-8.

4.3 Ciclo di vita di un global message nello store



Riferimenti: core-libs/core/src/global-message/facade/global-message.service.ts:L43-L72, core-libs/core/src/global-message/store/reducers/global-message.reducer.ts:L24-L67, core-libs/core/src/global-message/store/effects/global-message.effect.ts:L31-L106.

4.4 Fail action NgRx verso l'`ErrorHandler`



Riferimenti: §3.4.

5. Estratti di codice reale

5.1 ErrorHandlingModule

core-libs/core/src/error-handling/error-handling.module.ts:L13-L32

```ts
@NgModule({
  imports: [
    EffectsErrorHandlerModule.forRoot(),
    HttpErrorHandlerModule.forRoot(),
  ],
})
export class ErrorHandlingModule {
  static forRoot(): ModuleWithProviders<ErrorHandlingModule> {
    return {
      ngModule: ErrorHandlingModule,
      providers: [
        provideMultiErrorHandler(),
        {
          provide: ErrorHandler,
          useClass: CxErrorHandler,
        },
      ],
    };
  }
}
```

5.2 CxErrorHandler

core-libs/core/src/error-handling/cx-error-handler.ts:L18-L31

```ts
@Injectable()
export class CxErrorHandler implements ErrorHandler {
  protected errorHandlers = inject(MULTI_ERROR_HANDLER);

  /**
   * Error handler method. Handles the error by passing it to the registered multi error handlers.
   * @param error - The error to be handled.
   */
  handleError(error: unknown): void {
    this.errorHandlers.forEach((handler) => {
      handler.handleError(error);
    });
  }
}
```

5.3 `HttpErrorHandlerInterceptor` (cuore)

core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L40-L81

```ts
@Injectable({ providedIn: 'root' })
export class HttpErrorHandlerInterceptor implements HttpInterceptor {
  protected errorHandler = inject(ErrorHandler);
  protected occEndpointsService = inject(OccEndpointsService);
  protected windowRef = inject(WindowRef);

  protected userId = toSignal(inject(UserIdService).getUserId());

  intercept(
    request: HttpRequest<unknown>,
    next: HttpHandler
  ): Observable<HttpEvent<unknown>> {
    return next.handle(request).pipe(
      tap({
        error: (error: unknown) => {
          if (this.shouldHandleError(error)) {
            this.handleError(error);
          }
        },
      })
    );
  }
  // ...
  protected shouldHandleError(_error: unknown): boolean {
    return !this.windowRef.isBrowser();
  }

  protected handleError(error: unknown): void {
    error = this.isCmsPageNotFoundHttpError(error)
      ? new CmsPageNotFoundOutboundHttpError(error)
      : new OutboundHttpError(error);
    this.errorHandler.handleError(error);
  }
```

5.4 `HttpErrorInterceptor` (global message)

core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L22-L65

```ts
@Injectable({ providedIn: 'root' })
export class HttpErrorInterceptor implements HttpInterceptor {
  constructor(protected unifiedInjector: UnifiedInjector) {}

  protected handlers$: Observable<HttpErrorHandler[]> = this.unifiedInjector
    .getMulti(HttpErrorHandler)
    .pipe(shareReplay(1));
```

```
  intercept(
    request: HttpRequest<any>,
    next: HttpHandler
  ): Observable<HttpEvent<any>> {
    return next.handle(request).pipe(
      tap({
        error: (response: any) => {
          if (response instanceof HttpErrorResponse) {
            this.handleErrorResponse(request, response);
          }
        },
      })
    );
  }

  protected handleErrorResponse(
    request: HttpRequest<any>,
    response: HttpErrorResponse
  ): void {
    const handler = this.getResponseHandler(response);
    if (handler) {
      handler.handleError(request, response);
    }
  }
  // ...
  protected getResponseHandler(
    response: HttpErrorResponse
  ): HttpErrorHandler | undefined {
    return resolveApplicable(getLastValueSync(this.handlers$) ?? [], [
      response,
    ]);
  }
```

5.5 `resolveApplicable`: la regola di scelta

core-libs/core/src/util/applicable.ts:L63-L87

```ts
export function resolveApplicable<T extends Applicable>(
  applicables: T[],
  matchParams: any[] = [],
  priorityParams: any[] = []
): T | undefined {
  const matchedApplicables = (applicables ?? []).filter(
    (applicable) => !applicable.hasMatch || applicable.hasMatch(...matchParams)
  );

  if (matchedApplicables.length < 2) {
```

```
    return matchedApplicables[0];
  }

  let lastPriority = -Infinity;
  return matchedApplicables.reduce((acc: T | undefined, curr: T) => {
    const currPriority = curr.getPriority
      ? curr.getPriority(...priorityParams)
      : Priority.NORMAL;
    if (lastPriority > currPriority) {
      return acc;
    }
    lastPriority = currPriority;
    return curr;
  }, undefined);
}
```

Nota la condizione `lastPriority > currPriority`: a parità (`===`) non si ritorna `acc`, si sostituisce con `curr`. È questo che realizza "provided later wins".

5.6 `HttpErrorHandler` (classe base)

core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts:L12-L44

TS

```
@Injectable({
  providedIn: 'root',
})
export abstract class HttpErrorHandler implements Applicable {
  constructor(
    protected globalMessageService: GlobalMessageService,
    @Inject(PLATFORM_ID) protected platformId?: Object
  ) {}

  /**
   * The http response status number which is handled by this handler.
   * Implementations can set the response status number, i.e. 404, so that
   * the handler can be found by the error interceptor.
   */
  responseStatus?: number;
  // ...
  abstract handleError(
    request: HttpRequest<any>,
    errorResponse: HttpErrorResponse
  ): void;
  // ...
  hasMatch(errorResponse: HttpErrorResponse): boolean {
    return errorResponse.status === this.responseStatus;
  }
```

5.7 UnknownErrorHandler

core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L22-L50

```ts
export class UnknownErrorHandler extends HttpErrorHandler {
  protected logger = inject(LoggerService);

  responseStatus = HttpResponseStatus.UNKNOWN;

  /**
   * hasMatch always returns true, to mach all errors
   */
  hasMatch(_errorResponse: HttpErrorResponse): boolean {
    return true;
  }

  handleError(_request: HttpRequest<any>, errorResponse: HttpErrorResponse) {
    // Error is already handled and logged by the `HttpErrorHandlerInterceptor`.
    // Log error here only in dev mode.
    if (isDevMode()) {
      this.logger.warn(
        `An unknown http error occurred\n`,
        errorResponse.message
      );
    }
  }

  /**
   * Fallback priority assures that the handler is used as a last resort
   */
  getPriority() {
    return Priority.FALLBACK;
  }
}
```

5.8 ForbiddenHandler

core-libs/core/src/global-message/http-interceptors/handlers/forbidden/forbidden.handler.ts:L20-L50

```ts
export class ForbiddenHandler extends HttpErrorHandler {
  responseStatus = HttpResponseStatus.FORBIDDEN;

  handleError(request: HttpRequest<any>) {
    if (
      request.url.endsWith(
        this.occEndpoints.buildUrl('user', {
          urlParams: { userId: 'current' },
        })
```

```
      )
    ) {
      this.authService.logout();
    }
    this.globalMessageService.add(
      { key: 'httpHandlers.forbidden' },
      GlobalMessageType.MSG_TYPE_ERROR
    );
  }

  getPriority(): Priority {
    return Priority.LOW;
  }

  constructor(
    protected globalMessageService: GlobalMessageService,
    protected authService: AuthService,
    protected occEndpoints: OccEndpointsService
  ) {
    super(globalMessageService);
  }
}
```

5.9 `BadCartRequestHandler`: come una feature specializza il 400

feature-libs/cart/base/core/http-interceptors/handlers/bad-cart-request.handler.ts:L21-L38

TS

```
export class BadCartRequestHandler extends HttpErrorHandler {
  responseStatus = HttpResponseStatus.BAD_REQUEST;

  getPriority(): Priority {
    return Priority.NORMAL;
  }

  hasMatch(errorResponse: HttpErrorResponse): boolean {
    return (
      super.hasMatch(errorResponse) &&
      this.getErrors(errorResponse).some(isCartError)
    );
  }

  handleError(request: HttpRequest<any>, response: HttpErrorResponse): void {
    this.handleCartNotFoundError(request, response);
    this.handleOtherCartErrors(request, response);
  }
```

5.10 `ErrorActionService`

core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L24-L43

```ts
handle(action: ErrorAction): void {
  const error: unknown = action.error;

  // Http errors are already handled in HttpErrorHandlerInterceptor.
  // To avoid duplicate errors we want to check if the error is not of type
  // HttpErrorModel or HttpErrorResponse.
  const isNotHttpError =
    !(error instanceof HttpErrorModel) &&
    !(error instanceof HttpErrorResponse);

  if (isNotHttpError && this.shouldHandleError(error)) {
    this.errorHandler.handleError(error);
  }
}

/** Here we want to filter which error actions should be handled.
 * By default, we check if action implements interface ErrorAction  */
isErrorAction(action: Action): action is ErrorAction {
  return 'error' in action;
}
```

5.11 `GlobalMessageService.add` / `remove`

core-libs/core/src/global-message/facade/global-message.service.ts:L43-L72

```ts
add(
  text: string | Translatable,
  type: GlobalMessageType,
  timeout?: number
): void {
  this.store.dispatch(
    new GlobalMessageActions.AddMessage({
      text: typeof text === 'string' ? { raw: text } : text,
      type,
      timeout,
    })
  );
}
// ...
remove(type: GlobalMessageType, index?: number): void {
  this.store.dispatch(
    index !== undefined
      ? new GlobalMessageActions.RemoveMessage({
          type: type,
          index: index,
```

```
        })
      : new GlobalMessageActions.RemoveMessagesByType(type)
  );
}
```

5.12 hideAfterDelay$

core-libs/core/src/global-message/store/effects/global-message.effect.ts:L70-L106

```ts
hideAfterDelay$:
  | Observable<GlobalMessageActions.RemoveMessage>
  | (() => Observable<never>) = createEffect(() =>
  isPlatformBrowser(this.platformId) // we don't want to run this logic when doing SSR
    ? this.actions$.pipe(
        ofType(GlobalMessageActions.ADD_MESSAGE),
        map((action) => (action as GlobalMessageActions.AddMessage).payload),
        concatMap((message) => {
          const config = this.config.globalMessages?.[message.type];
          return this.store.pipe(
            select(
              GlobalMessageSelectors.getGlobalMessageCountByType(message.type)
            ),
            take(1),
            filter(
              (count: number) =>
                ((config && config.timeout !== undefined) ||
                  message.timeout !== undefined) &&
                count > 0
            ),
            delay((message.timeout as number) || (config?.timeout as number)),
            switchMap(() =>
              of(
                new GlobalMessageActions.RemoveMessage({
                  type: message.type,
                  index: 0,
                })
              )
            )
          );
        })
      )
    : // workaround is required due to NGRX mutating a global static
      // observable EMPTY, causing to throw an error if we have
      // effect registered on the same observable twice
      () => EMPTY
);
```

5.13 LoggerService

core-libs/core/src/logger/logger.service.ts:L15-L30

```ts
@Injectable({
  providedIn: 'root',
})
export class LoggerService {
  log(...args: Parameters<typeof console.log>): void {
    /* eslint-disable-next-line no-console */
    console.log(...args);
  }
  warn(...args: Parameters<typeof console.warn>): void {
    /* eslint-disable-next-line no-console */
    console.warn(...args);
  }
  error(...args: Parameters<typeof console.error>): void {
    /* eslint-disable-next-line no-console */
    console.error(...args);
  }
  // ...
```

5.14 Il ponte verso Express

core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32

```ts
export const defaultExpressErrorHandlers =
  (documentContent: string): ErrorRequestHandler =>
  (err, _req, res, _next) => {
    if (!res.headersSent) {
      res.set('Cache-Control', 'no-store');
      const statusCode =
        err instanceof CmsPageNotFoundOutboundHttpError
          ? HttpResponseStatus.NOT_FOUND
          : HttpResponseStatus.INTERNAL_SERVER_ERROR;
      res.status(statusCode).send(documentContent);
    }
  };
```

6. Configurazione

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
`globalMessages[MSG_TYPE_CONFIRMATION].timeout`	`number?` (ms)	3000	`core-libs/core/src/global-message/config/global-message-config.ts:L15-L27`; default `core-libs/core/src/global-message/config/default-global-message-config.ts:L12-L14`	`core-libs/core/src/global-message/store/effects/global-message.effect.ts:L78-L90`
`globalMessages[MSG_TYPE_INFO].timeout`	`number?`	3000	idem; default `core-libs/core/src/global-message/config/default-global-message-config.ts:L15-L17`	idem
`globalMessages[MSG_TYPE_ERROR].timeout`	`number?`	7000	idem; default `core-libs/core/src/global-message/config/default-global-message-config.ts:L18-L20`	idem
`globalMessages[MSG_TYPE_WARNING].timeout`	`number?`	7000	idem; default `core-libs/core/src/global-message/config/default-global-message-config.ts:L21-L23`	idem
`globalMessages[MSG_TYPE_ASSISTIVE].timeout`	`number?`	7000	idem; default `core-libs/core/src/global-message/config/default-global-message-config.ts:L24-L26`	idem
`timeout` del singolo messaggio (3° argomento di `GlobalMessageService.add`)	`number?`	`undefined`	`core-libs/core/src/global-message/facade/global-message.service.ts:L43-L54`	`core-libs/core/src/global-message/store/effects/global-message.effect.ts:L86-L90` (prevale se truthy)
feature toggle `enablePasswordExpiredErrorTranslation`	`boolean?`	`true`	`core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L174-L179`; default `core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1031-L1031`	`core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L50-L57`
feature toggle `a11yFilteredFacetAnnouncement`	`boolean?`	`false`	`core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L333-L333`; default `core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1054-L1054`	`core-libs/storefront/cms-components/misc/global-message/global-message.component.html:L1-L24`: se attivo, i messaggi `MSG_TYPE_ASSISTIVE` vanno in un'unica live region `aria-live="polite"`; se disattivo, viene creata una live region per ogni messaggio

Note:

- `GlobalMessageTypeConfig` contiene **solo** `timeout` — core-libs/core/src/global-message/config/global-message-config.ts:L11-L13. `GlobalMessageConfig` è `providedIn: 'root'` con `useExisting: Config` e arricchisce `Config` via module augmentation — core-libs/core/src/global-message/config/global-message-config.ts:L15-L31. Si configura quindi con `provideConfig({ globalMessages: { ... } })` come qualsiasi altra chiave (vedi 11 — Configurazione).
- Il default è registrato con `provideDefaultConfig(defaultGlobalMessageConfig)` — core-libs/core/src/global-message/global-message.module.ts:L24-L24; `defaultGlobalMessageConfig` non è esportato dal barrel pubblico — core-libs/core/src/global-message/index.ts:L7-L16.
- Non esistono chiavi di configurazione per l'error handling (`MULTI_ERROR_HANDLER`, `shouldHandleError`, logger): si personalizza solo via DI (§8). I toggle in generale sono trattati in 42 — Feature toggle e deprecazioni.

---

7. Commenti e note notevoli dal sorgente

- "The CxErrorHandler is the default ErrorHandler for Spartacus. ... The prefix `Cx` was used to distinguish it from Angular's `ErrorHandler` class." — core-libs/core/src/error-handling/cx-error-handler.ts:L10-L17.
- "CAUTION: It MUST be provided as the first one in the application to be able to catch errors from all subsequent interceptors." — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L27-L39. Il contraltare in `BaseCoreModule`: "Import this module before any other interceptor to handle HTTP errors efficiently" — core-libs/core/src/base-core.module.ts:L28-L28.
- "Be default, we avoid sending unpredictable errors to the browser's console, to prevent possibly exposing there potentially confidential user's data. This isn't an issue in SSR, where pages are rendered anonymously." — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L63-L71 (testo identico, refuso "Be default" compreso, in core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L45-L53).
- "It ensures that HTTP errors, which are already handled by `HttpErrorHandlerInterceptor`, are not processed again to avoid duplicate error handling." — core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L14-L18.
- "Multi provided error handlers will be called in the order they are provided." — core-libs/core/src/error-handling/multi-error-handler/multi-error-handler.ts:L20-L23.
- "Intentional empty error handler to avoid we fallabck to the unknown error handler" — core-libs/core/src/global-message/http-interceptors/handlers/not-found/not-found.handler.ts:L19-L19.
- "Error is already handled and logged by the `HttpErrorHandlerInterceptor`. Log error here only in dev mode." — core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L35-L36. Vero solo in SSR: vedi §9, trappola 1.
- "return the error handler that matches the `HttpResponseStatus` code. If no handler is available, the UNKNOWN handler is returned." — core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L55-L58.
- "Updating email and changing password share same http error occurence." — core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L76-L77.
- "Added in 3.2, depends on the injected `platformId`." (su `isSsr()`) — core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts:L63-L67.
- "workaround is required due to NGRX mutating a global static observable EMPTY, causing to throw an error if we have effect registered on the same observable twice" — core-libs/core/src/global-message/

store/effects/global-message.effect.ts:L102-L105.

- "It's a good extension point for customizing the destination of logs (e.g. to use a 3rd party logger library) or to enhance logs with more contextual data." — core-libs/core/src/logger/logger.service.ts:L9-L14.
- "Should be used with caution, as it's not a legitimate way for getting value from the observable." (su getLastValueSync) — core-libs/core/src/util/rxjs/get-last-value-sync.ts:L13-L15.
- "CXSPA-11104: Revise type to avoid redundant types - typescript:S6571" — core-libs/core/src/util/try-normalize-http-error.ts:L28-L28.
- "We need it until Angular implements a proper propagation of async errors ... https://github.com/angular/angular/issues/33642" — core-libs/setup/ssr/error-handling/multi-error-handlers/propagating-to-server-error-handler.ts:L18-L20.
- La proprietà error aggiunta "to be recognizable by CxErrorHandlerEffect (which expects error property in every fail action)" — feature-libs/pickup-in-store/core/store/actions/pickup-location.action.ts:L83-L87.
- Nei 55 file dell'area non ci sono @deprecated, TODO o FIXME (dossier, sezione N).

---

8. Extension point

COSA VUOI FARE	EXTENSION POINT	DEFINIZIONE	PUBBLICO?
Messaggio custom per uno status o per un sotto-caso di uno status	nuovo HttpErrorHandler multi-provider con getPriority() > LOW e/o hasMatch più stretto	core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts:L15-L74	sì, core-libs/core/src/global-message/index.ts:L10-L10
Modificare un handler esistente	estendere BadRequestHandler, ForbiddenHandler, … e registrarlo con priorità maggiore	core-libs/core/src/global-message/http-interceptors/handlers/index.ts:L7-L15	sì
Mostrare/rimuovere messaggi da codice applicativo	GlobalMessageService	core-libs/core/src/global-message/facade/global-message.service.ts:L21-L73	sì, core-libs/core/src/global-message/index.ts:L8-L8
Cambiare i timeout	GlobalMessageConfig via provideConfig	core-libs/core/src/global-message/config/global-message-config.ts:L15-L27	sì, core-libs/core/src/global-message/index.ts:L7-L7
Leggere lo store direttamente	GlobalMessageSelectors, GlobalMessageActions, GLOBAL_MESSAGE_FEATURE	core-libs/core/src/global-message/store/selectors/index.ts:L7-L8, core-libs/core/src/global-message/store/actions/index.ts:L7-L8	sì, core-libs/core/src/global-message/index.ts:L14-L16
Inviare gli errori a un servizio esterno (Sentry, APM…)	nuovo MultiErrorHandler su MULTI_ERROR_HANDLER (multi: true)	core-libs/core/src/error-handling/multi-error-handler/multi-error-handler.ts:L16-L27	sì, core-libs/core/src/error-handling/multi-error-handler/index.ts:L8-L8
Cambiare destinazione/formato dei log	sostituire LoggerService (useClass/useExisting)	core-libs/core/src/logger/logger.service.ts:L15-L39	sì, core-libs/core/src/logger/index.ts:L7-L7

COSA VUOI FARE	EXTENSION POINT	DEFINIZIONE	PUBBLICO?
Inoltrare errori HTTP all'`ErrorHandler` anche nel browser, o filtrarli	estendere `HttpErrorHandlerInterceptor` e sovrascrivere `shouldHandleError` (protected)	core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L72-L98	sì, core-libs/core/src/error-handling/http-error-handler/index.ts:L7-L7
Decidere quali fail action contano come errore	estendere `ErrorActionService` (`isErrorAction`, `shouldHandleError`)	core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L41-L56	sì, core-libs/core/src/error-handling/effects-error-handler/index.ts:L9-L9
Far riconoscere una fail action custom	implementare `ErrorAction` (proprietà `error`)	core-libs/core/src/error-handling/effects-error-handler/error-action.ts:L9-L11	sì
Sostituire del tutto l'`ErrorHandler`	`{ provide: ErrorHandler, useClass: ... }`	core-libs/core/src/error-handling/error-handling.module.ts:L25-L28	`CxErrorHandler` pubblico, core-libs/core/src/error-handling/index.ts:L7-L7
Distinguere errori lato server	`OutboundHttpError`, `CmsPageNotFoundOutboundHttpError` (`instanceof`)	core-libs/core/src/error-handling/http-error-handler/outbound-http-error.ts:L10-L25	sì
Silenziare il logger nei test	`LoggerTestingModule` / `MockLoggerService`	core-libs/core/src/logger/testing/logger-testing.module.ts:L11-L14	sì, core-libs/core/src/logger/index.ts:L8-L8

Non sono extension point pubblici: `HttpErrorInterceptor` (importato ma non riesportato da core-libs/core/src/global-message/http-interceptors/index.ts:L20-L20), `CxErrorHandlerEffect` (core-libs/core/src/error-handling/effects-error-handler/index.ts:L7-L9), `GlobalMessageEffect`, il reducer, `defaultGlobalMessageConfig` (core-libs/core/src/global-message/index.ts:L7-L16) e `provideMultiErrorHandler` (core-libs/core/src/error-handling/multi-error-handler/index.ts:L7-L8). Vedi 54 — API pubblica vs interna.

8.1 Schema: handler custom per uno status

Esempio illustrativo (nomi applicativi inventati, simboli Spartacus esportati da `@spartacus/core`), costruito sullo stesso schema di `BadCartRequestHandler` (§5.9) e della sua registrazione (feature-libs/cart/base/core/cart-base-core.module.ts:L37-L41):

```ts
// ESEMPIO — non presente nel repository
@Injectable({ providedIn: 'root' })
export class MyNotFoundHandler extends HttpErrorHandler {
  responseStatus = HttpResponseStatus.NOT_FOUND;

  hasMatch(errorResponse: HttpErrorResponse): boolean {
    return super.hasMatch(errorResponse) && /* condizione specifica */ true;
  }

  handleError(_request: HttpRequest<any>, _response: HttpErrorResponse): void {
    this.globalMessageService.add(
```

```
      { key: 'myApp.notFound' },
      GlobalMessageType.MSG_TYPE_WARNING
    );
  }

  getPriority(): Priority {
    return Priority.NORMAL; // > LOW del NotFoundHandler di default
  }
}

// providers: [{ provide: HttpErrorHandler, useExisting: MyNotFoundHandler, multi: true }]
```

Vincoli verificati sul codice: il provider deve essere `multi: true`, altrimenti `UnifiedInjector.getMulti` lancia "Multi-providers mixed with single providers" (core-libs/core/src/lazy-loading/unified-injector.ts:L79-L93); se l'handler vive in un modulo lazy viene visto solo dopo il caricamento di quel modulo (core-libs/core/src/lazy-loading/unified-injector.ts:L32-L35).

8.2 Schema: multi error handler verso un servizio esterno

TS

```
// ESEMPIO — non presente nel repository
@Injectable({ providedIn: 'root' })
export class ApmErrorHandler implements MultiErrorHandler {
  handleError(error: unknown): void {
    // inviare error al servizio esterno; non lanciare mai da qui
  }
}

// providers: [{ provide: MULTI_ERROR_HANDLER, useExisting: ApmErrorHandler, multi: true }]
```

Ricorda che i default di Spartacus inoltrano a `ErrorHandler` errori HTTP e fail action **solo in SSR** (§3.3, §3.4); per raccoglierli anche nel browser serve sovrascrivere `shouldHandleError` in `HttpErrorHandlerInterceptor` / `ErrorActionService` — tenendo conto della motivazione di privacy del commento originale (§7).

Ricette correlate in Parte III:

- 50 — Ricette: configurazione, DI, interceptor, eventi: override di servizi via DI (`LoggerService`, `ErrorActionService`, `HttpErrorHandlerInterceptor`), multi-provider, interceptor custom e loro posizione nella catena.
- 53 — Ricette: feature lib lazy, carrello/checkout, stili, traduzioni: override delle chiavi `httpHandlers.*` e aggiunta di chiavi per handler custom.
- 54 — API pubblica vs interna, upgrade, anti-pattern, checklist: perché non estendere `HttpErrorInterceptor` o `CxErrorHandlerEffect` (non esportati).

9. Trappole, casi limite, comportamenti controintuitivi

1. **Nel browser il** `LoggingErrorHandler` **non vede errori HTTP né fail action.** Sia `HttpErrorHandlerInterceptor` sia `ErrorActionService` filtrano con `!isBrowser()`; il commento dell'`UnknownErrorHandler` ("already handled and logged by the HttpErrorHandlerInterceptor") è vero solo in SSR. Nel browser un errore di rete/timeout non lascia traccia in produzione — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L72-L74, core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L54-L56, core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L35-L42.
2. **Un solo handler per errore.** `HttpErrorInterceptor` invoca solo l'handler con priorità più alta: un handler custom con priorità maggiore **sostituisce** il default per quella risposta, non si somma — core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L45-L53, core-libs/core/src/util/applicable.ts:L76-L86.
3. **Priorità di default bassa.** Tutti gli handler di default sono LOW (Unknown FALLBACK): un handler custom senza `getPriority` vale NORMAL e vince; a parità vince il provider registrato più tardi, anche se in un modulo lazy — core-libs/core/src/util/applicable.ts:L54-L57, core-libs/core/src/lazy-loading/unified-injector.ts:L79-L93. Attenzione però: `getPriority` è dichiarato `abstract getPriority?()` nella base, quindi è opzionale anche per TypeScript — core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts:L61-L61.
4. `hasMatch` **troppo largo = handler che "mangia" tutto.** Se sovrascrivi `hasMatch` restituendo `true` (come `UnknownErrorHandler`) con priorità > FALLBACK, intercetti ogni status — core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L30-L32.
5. **Ordine degli interceptor.** `ErrorHandlingModule` deve restare il primo import con interceptor: gli errori lanciati da un interceptor registrato prima (quindi più esterno) non attraversano `HttpErrorHandlerInterceptor` e non arrivano all'`ErrorHandler`. Viceversa, un interceptor registrato dopo (più interno) che cattura o sostituisce l'errore gli consegna un errore già trasformato, o nessuno — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L37-L38, core-libs/core/src/base-core.module.ts:L28-L28, angular:packages/common/http/src/interceptor.ts:L233-L240.
6. **Il 401 non ha handler.** `UNAUTHORIZED` è nell'enum ma non tra i registrati; se un 401 sfugge all'auth interceptor cade nell'`UnknownErrorHandler` (nessun messaggio) — core-libs/core/src/global-message/models/response-status.model.ts:L10-L10, core-libs/core/src/global-message/http-interceptors/index.ts:L22-L63.
7. **Timeout e rete sono silenziosi.** Status 0 → `UnknownErrorHandler` → solo `warn` in dev mode; la chiave `httpHandlers.unknownError` esiste nelle traduzioni ma questo handler non la usa — core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L34-L43, core-libs/assets/src/translations/en/common.json:L131-L131.
8. `HttpErrorInterceptor` **ignora errori non HTTP**, mentre `HttpErrorHandlerInterceptor` li inoltra tutti — core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L37-L39, core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L54-L58.
9. **Il 404 è volutamente muto** (`NotFoundHandler` vuoto): per le pagine CMS il 404 è gestito dal `CmsPageGuardService`, che carica la pagina CMS `notFound` e la associa al contesto richiesto (core-libs/storefront/cms-structure/guards/cms-page-guard.service.ts:L112-L127), e in SSR diventa un 404 HTTP via `CmsPageNotFoundOutboundHttpError` — core-libs/core/src/global-message/http-interceptors/handlers/not-found/not-found.handler.ts:L18-L20, core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L26-L29.

10. **403 e logout.** `ForbiddenHandler` fa `logout()` solo se l'URL termina con quello OCC di `users/current`; per altri 403 mostra solo il messaggio — core-libs/core/src/global-message/http-interceptors/handlers/forbidden/forbidden.handler.ts:L24-L32.
11. **Un 400 può produrre molti messaggi.** I sei sotto-handler di `BadRequestHandler` girano tutti, uno `add` per ogni `ErrorModel` corrispondente — core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L26-L33.
12. **Testo backend non tradotto.** `IllegalArgumentError` e `UnknownIdentifierError` (con message) mostrano `error.message` raw del backend — core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L106-L118, core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L143-L152.
13. **Presupposti sul formato della richiesta.** `handleBadPassword` chiama `request.body?.get('grant_type')` (presuppone `HttpParams`), `handleBadLoginResponse` usa `new URL(_request.url)` — core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L42-L42, core-libs/core/src/global-message/http-interceptors/handlers/bad-request/bad-request.handler.ts:L78-L78. DA VERIFICARE — con un URL relativo (es. `occ.baseUrl` vuoto) il costruttore `URL` senza base lancerebbe; il caso non è coperto da test nel dossier.
14. `hideAfterDelay$` **rimuove l'indice 0, non "quel" messaggio.** Se l'utente chiude manualmente un messaggio, il timer successivo rimuoverà un altro messaggio dello stesso tipo — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L91-L97.
15. **Timer serializzati.** `concatMap` accoda i timer: con tre errori, il secondo inizia a contare solo dopo la scadenza del primo — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L77-L77.
16. `timeout: 0` **non significa "subito".** Supera il filtro (`!== undefined`) ma `delay(0 || config.timeout)` usa il timeout di config — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L86-L90.
17. **Il** `timeout` **non arriva allo store**: il reducer salva solo `text`, quindi non puoi leggerlo da un selettore — core-libs/core/src/global-message/store/reducers/global-message.reducer.ts:L32-L41.
18. **Dedup che sposta in fondo.** `removeDuplicated$` rimuove la prima occorrenza (la più vecchia), così il messaggio riappare in coda — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L52-L62. Il timer del primo `ADD_MESSAGE` resta però in coda in `concatMap` e, alla scadenza, rimuove l'indice 0. Nel caso di un singolo messaggio duplicato, il messaggio sparisce alla scadenza del timer originale; il timer del nuovo `ADD_MESSAGE` trova `count = 0` e non fa nulla — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L77-L97. Il confronto è deep-equal sul `Translatable`: stessa key con `params` diversi = due messaggi distinti — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L47-L51.
19. **In SSR i messaggi non scadono** (`hideAfterDelay$ = () => EMPTY`) — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L73-L105.
20. `RemoveMessagesByType` **lascia** `[]`, non elimina la chiave; `RemoveMessage` con indice fuori range è un no-op (`splice`) — core-libs/core/src/global-message/store/reducers/global-message.reducer.ts:L57-L58, core-libs/core/src/global-message/store/reducers/global-message.reducer.ts:L69-L73.
21. `isErrorAction` **è "duck typing" puro**: qualunque action con chiave `error` (anche `undefined`) è considerata d'errore — core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L41-L43. Viceversa una fail action **senza** `error` sfugge (vedi il commento in pickup-in-store, feature-libs/pickup-in-store/core/store/actions/pickup-location.action.ts:L83-L87).
22. **Override di** `isErrorAction` **e** `this`**.** L'effect passa il metodo non legato: `filter(this.errorActionService.isErrorAction)` — core-libs/core/src/error-handling/effects-error-handler/cx-error-handler.effect.ts:L25-L26; RxJS lo invoca con `predicate.call(thisArg, ...)` e `thisArg` assente — deps:rxjs-7.8.2/package/dist/cjs/internal/operators/filter.js:L6-L11. Un override che usi `this` (es. per iniettare

dipendenze) troverà `this === undefined`: usa una arrow function come proprietà o non dipendere da `this`.

23. **Fail action con `HttpErrorResponse` grezzo**: viene scartata comunque (`instanceof HttpErrorResponse`), anche se non normalizzata — `core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L30-L32`.
24. **Un multi handler che lancia blocca gli altri.** `CxErrorHandler` itera senza `try/catch` — `core-libs/core/src/error-handling/cx-error-handler.ts:L26-L30`. In SSR `LoggingErrorHandler` è registrato prima di `PropagatingToServerErrorHandler`; un handler custom aggiunto in mezzo che lancia impedirebbe la propagazione al server.
25. `provideMultiErrorHandler` **non è pubblico**: per aggiungere handler usa direttamente `MULTI_ERROR_HANDLER` con `multi: true` — `core-libs/core/src/error-handling/multi-error-handler/index.ts:L7-L8`.
26. `userId` **del signal.** `isCmsPageNotFoundHttpError` usa il valore corrente del signal `userId` per costruire l'URL atteso — `core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L46-L46`, `core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L90-L92`. `UserIdService._userId` è un `ReplaySubject<string>(1)` senza valore iniziale (`core-libs/core/src/auth/user-auth/facade/user-id.service.ts:L25-L25`): finché nessuno chiama `setUserId` il signal vale `undefined` e l'URL atteso potrebbe non corrispondere. DA VERIFICARE — l'effetto concreto sul confronto URL non è verificato a runtime.
27. `isSsr()` **falso negativo.** Restituisce `false` se la sottoclasse non passa `platformId` a `super`, come fa `ForbiddenHandler` — `core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts:L68-L73`, `core-libs/core/src/global-message/http-interceptors/handlers/forbidden/forbidden.handler.ts:L48-L48`.
28. **Errori di effect vs fail action.** Un errore non catturato in un effect arriva a `CxErrorHandler` tramite il `defaultEffectsErrorHandler` di NgRx anche nel browser (e l'effect viene risottoscritto fino a 10 volte) — `deps:ngrx-effects-21.0.1/package/fesm2022/ngrx-effects.mjs:L174-L185`.
29. `getLastValueSync` **"funziona per costruzione"**: solo perché `injectors$` emette sincronamente il root injector (`startWith`) e `shareReplay(1)` memorizza l'ultimo array — `core-libs/core/src/lazy-loading/unified-injector.ts:L32-L35`, `core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L26-L28`.

---

10. Come fare debug

- **Quale handler ha gestito l'errore?** Metti un breakpoint in `HttpErrorInterceptor.handleErrorResponse` e ispeziona `handler` (`core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L49-L52`). Per vedere *tutti* i candidati, ispeziona il risultato di `getLastValueSync(this.handlers$)` in `getResponseHandler` (`core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L62-L64`) e confronta `responseStatus` e `getPriority()` di ciascuno con le regole di `core-libs/core/src/util/applicable.ts:L63-L87`.
- **Il mio handler custom non viene usato.** Verifica: (a) `multi: true` sul provider (`core-libs/core/src/lazy-loading/unified-injector.ts:L83-L88`); (b) priorità > LOW o `hasMatch` corretto; (c) se è in un modulo lazy, che il modulo sia già caricato al momento dell'errore (`core-libs/core/src/lazy-loading/unified-injector.ts:L32-L35`).
- **Nessun messaggio a video.** Status 0 (timeout/rete), 401 o 404 non producono messaggi di default (§9 punti 6, 7, 9). Con Redux DevTools cerca le action `[Global-message] Add a Message` (`core-libs/core/src/global-message/store/actions/global-message.actions.ts:L13-L16`): se ci sono, il problema è nel rende-

ring (`cx-global-message` deve essere nel layout, importato via `GlobalMessageComponentModule` da core-libs/storefront/base-storefront.module.ts:L26-L30) o nelle traduzioni mancanti.

- **Messaggi che spariscono "a caso".** Ricorda indice 0 e `concatMap` (§9 punti 14-15). Seguire nella timeline le coppie `Add a Message` / `Remove a Message` e il loro `index`.
- **Errori in dev mode.** `UnknownErrorHandler` scrive `An unknown http error occurred` via `LoggerService.warn` solo con `isDevMode()` (core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L37-L42); `tryNormalizeHttpError` scrive `Error passed to tryNormalizeHttpError is not HttpErrorResponse instance` se riceve un errore non HTTP (core-libs/core/src/util/try-normalize-http-error.ts:L59-L65).
- **SSR risponde 500 inatteso.** Cerca nei log server l'`Outbound HTTP Error` scritto da `LoggingErrorHandler` (core-libs/core/src/error-handling/multi-error-handler/logging-error-handler.ts:L23-L25) e ispeziona la sua `cause` (core-libs/core/src/error-handling/http-error-handler/outbound-http-error.ts:L10-L14): è la richiesta OCC fallita. Un errore non HTTP proveniente da una fail action arriva invece "nudo" (§3.4). Approfondimento in 39 — SSR ottimizzato.
- **Simulare il comportamento SSR nel browser.** Un `HttpErrorHandlerInterceptor` esteso con `shouldHandleError` che restituisce `true` fa passare gli errori HTTP da `CxErrorHandler` anche lato client (core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L72-L74) — solo in sviluppo, per la nota di privacy di §7.
- **Test unitari rumorosi.** Importa `LoggerTestingModule` (sostituisce `LoggerService` con `MockLoggerService`) — core-libs/core/src/logger/testing/logger-testing.module.ts:L11-L14. Vedi 44 — Strategia di test.

---

11. Domande di autoverifica

1. **Perché `ErrorHandlingModule.forRoot()` è il primo import di `BaseCoreModule`?** Perché registra `HttpErrorHandlerInterceptor`, che deve essere il più esterno per vedere gli errori di tutti gli interceptor successivi; Angular annida gli interceptor con `reduceRight`, quindi il primo registrato è l'ultimo a ricevere l'errore. — core-libs/core/src/base-core.module.ts:L26-L29, core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L37-L38, angular:packages/common/http/src/interceptor.ts:L232-L240.
2. **Un backend risponde 500 nel browser. Quante volte viene chiamato `CxErrorHandler`?** Zero (per questo percorso): `HttpErrorInterceptor` mostra `httpHandlers.internalServerError`, ma `HttpErrorHandlerInterceptor.shouldHandleError` è `false` nel browser. — core-libs/core/src/global-message/http-interceptors/handlers/internal-server/internal-server.handler.ts:L16-L28, core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L72-L74.
3. **Registro un handler per il 400 senza `getPriority`. Chi vince fra il mio, `BadRequestHandler` e `UnknownErrorHandler`?** Il mio: senza `getPriority` vale NORMAL (0), che batte LOW (−10) e FALLBACK (−50). — core-libs/core/src/util/applicable.ts:L7-L24, core-libs/core/src/util/applicable.ts:L76-L86.
4. **Due handler con la stessa priorità e lo stesso `hasMatch`: quale viene scelto?** Quello registrato più tardi, perché il `reduce` sostituisce l'accumulatore quando `lastPriority <= currPriority`. — core-libs/core/src/util/applicable.ts:L54-L57, core-libs/core/src/util/applicable.ts:L81-L85.
5. **Perché un timeout HTTP non mostra alcun messaggio di default?** `HttpTimeoutInterceptor` produce un `HttpErrorResponse` con status 0; nessun handler ha quello status, quindi vince `UnknownErrorHandler`, che fa solo `warn` in dev mode. — core-libs/core/src/http/http-timeout/http-timeout.interceptor.ts:L101-L110, core-libs/core/src/global-message/http-interceptors/handlers/unknown-error/unknown-error.handler.ts:L34-L43.

6. **In SSR, come fa il server a rispondere 404 invece di 500 per una pagina CMS inesistente?** `HttpErrorHandlerInterceptor` riconosce il 404 sull'endpoint `pages` e crea `CmsPageNotFoundOutboundHttpError`; `PropagatingToServerErrorHandler` lo propaga e `defaultExpressErrorHandlers` lo mappa su 404 con `instanceof`. — core-libs/core/src/error-handling/http-error-handler/http-error-handler.interceptor.ts:L76-L98, core-libs/setup/ssr/error-handling/multi-error-handlers/propagating-to-server-error-handler.ts:L35-L37, core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L26-L30.
7. **Una fail action porta un `HttpErrorModel`. Arriva all'`ErrorHandler` in SSR?** No: `ErrorActionService.handle` scarta `HttpErrorModel` e `HttpErrorResponse` perché già gestiti dall'interceptor, evitando il doppio log. — core-libs/core/src/error-handling/effects-error-handler/error-action.service.ts:L27-L36.
8. **Chiamo `globalMessageService.add('Salvato', MSG_TYPE_CONFIRMATION, 0)`. Dopo quanto sparisce?** Dopo 3000 ms: `timeout: 0` passa il filtro `!== undefined`, ma `delay(0 || config.timeout)` usa il default di config per CONFIRMATION. Inoltre la stringa diventa `{ raw: 'Salvato' }`. — core-libs/core/src/global-message/store/effects/global-message.effect.ts:L84-L90, core-libs/core/src/global-message/config/default-global-message-config.ts:L12-L14, core-libs/core/src/global-message/facade/global-message.service.ts:L50-L50.
9. **Come aggiungo l'invio degli errori a un servizio esterno senza perdere il logging di default?** Registrando un `MultiErrorHandler` su `MULTI_ERROR_HANDLER` con `multi: true` (il token è pubblico; `provideMultiErrorHandler` no); `CxErrorHandler` chiamerà tutti gli handler in ordine. — core-libs/core/src/error-handling/multi-error-handler/multi-error-handler.ts:L16-L27, core-libs/core/src/error-handling/cx-error-handler.ts:L26-L30, core-libs/core/src/error-handling/multi-error-handler/index.ts:L7-L8.
10. **Perché un 403 su `users/current` causa un logout, ma un 403 su un altro endpoint no?** `ForbiddenHandler` confronta `request.url` con `occEndpoints.buildUrl('user', { urlParams: { userId: 'current' } })` tramite `endsWith` e chiama `authService.logout()` solo in quel caso; il messaggio `httpHandlers.forbidden` è mostrato sempre. — core-libs/core/src/global-message/http-interceptors/handlers/forbidden/forbidden.handler.ts:L23-L37.

TAVOLA 41.1 **4.1 Registrazione e ordine della catena di interceptor**

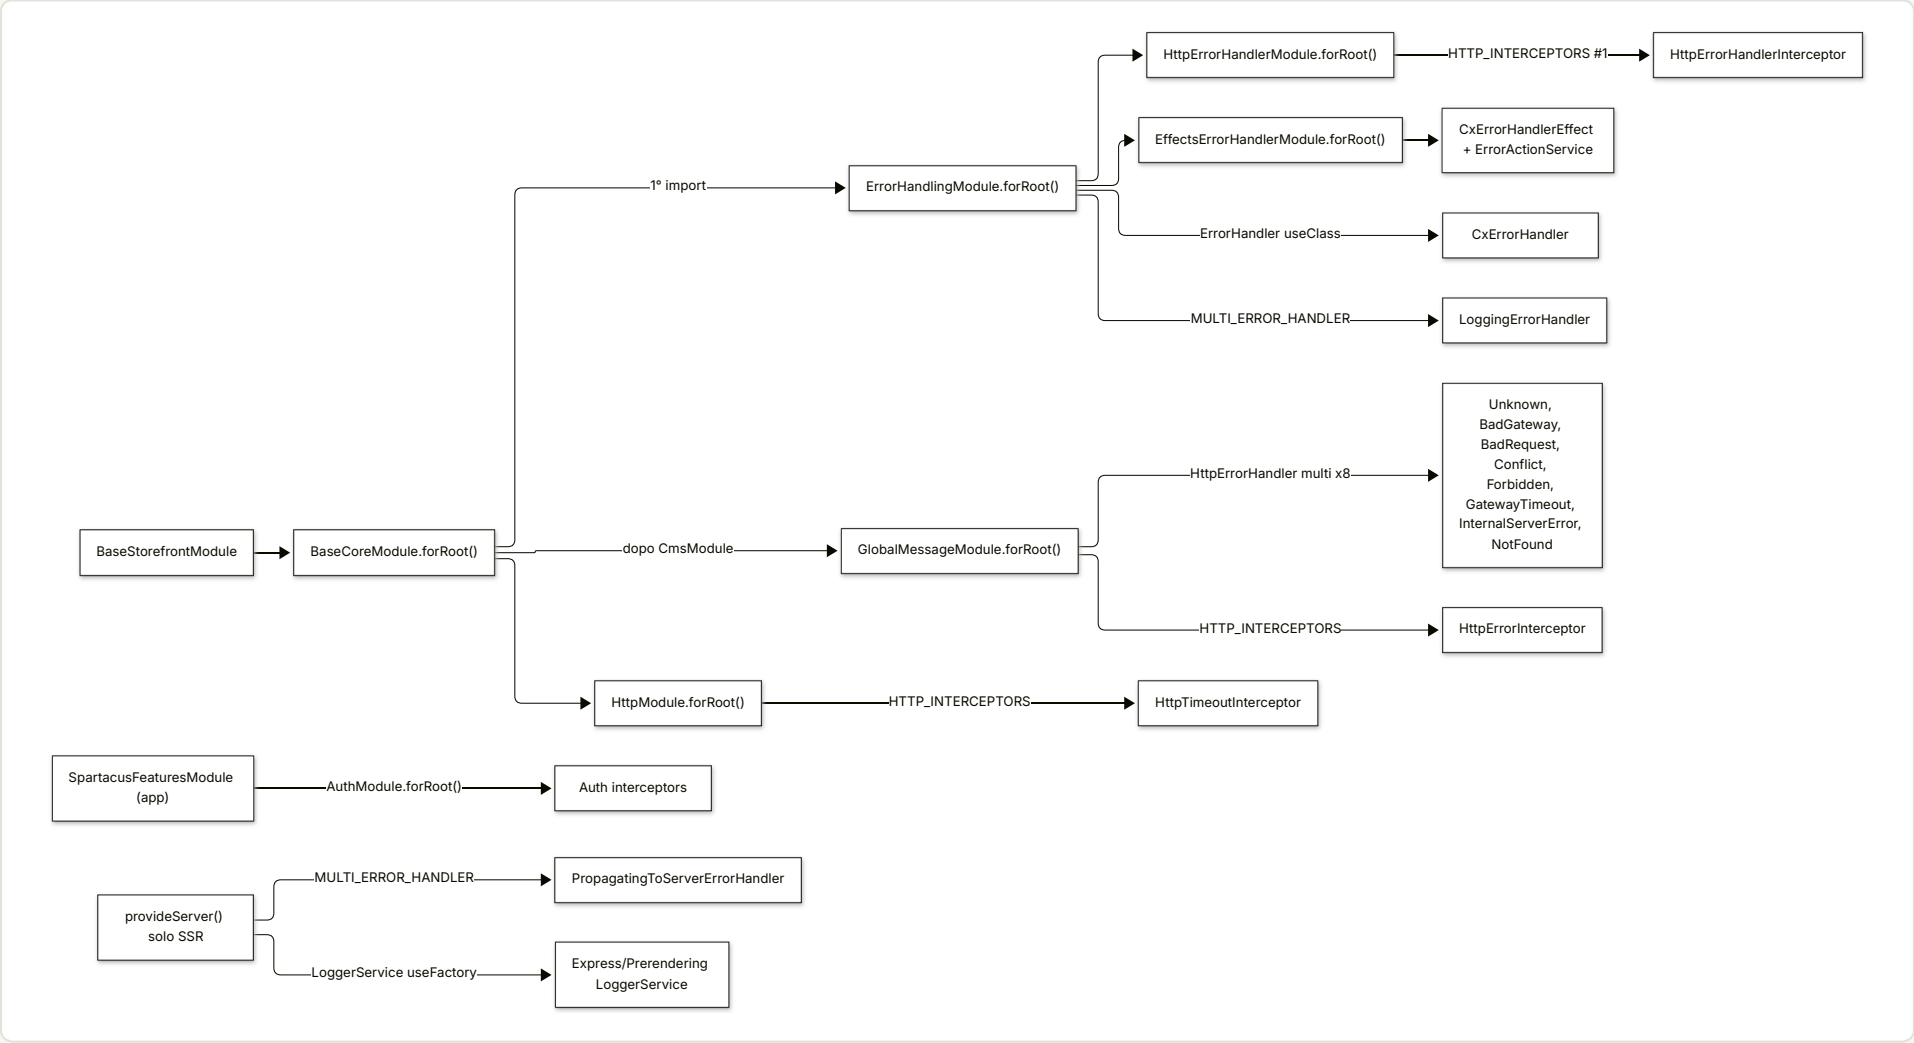


TAVOLA 41.2 **4.2 Un errore 500 che risale la catena: browser vs SSR**

Riferimenti allo SHA `5b7a1c2bf2808d7380bc20596d10f4fa710c3da1` (vedi 00-meta).

1. A cosa serve e perché esiste

Spartacus è una libreria che i clienti estendono per ereditarietà, sostituzione via DI e override SCSS. Ogni correzione che cambia DOM, stili o comportamento rischia quindi di rompere un'estensione a valle. La risposta del progetto è un meccanismo di **feature toggle**: la correzione viene scritta accanto al vecchio comportamento, protetta da un flag booleano con nome, e il cliente la attiva quando è pronto. Lo dice la JSDoc del token principale: "Properties for gradual adaptation to breaking changes in Spartacus via feature toggles. Each toggle has its own lifespan defined in the official docs." (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L10-L14).

Allo SHA convivono **due generazioni** di API:

GENERAZIONE	SIMBOLI	STATO	DOVE LEGGE
Legacy	`FeaturesConfig` (`features.*` dentro il `Config` globale), `FeatureConfigService.isEnabled/isLevel`, `features.level`, `FeatureLevelDirective`	`@deprecated` (core-libs/core/src/features-config/config/features-config.ts:L10-L26, core-libs/core/src/features-config/services/feature-config.service.ts:L15-L22)	`Config.features`, costruito con `deepMerge`
Attuale	`FeatureToggles` (classe astratta DI + interfaccia), `provideFeatureToggles(...)`, `provideDefaultFeatureToggles(...)`	raccomandata (core-libs/core/src/features-config/config/features-config.ts:L10-L26)	oggetto piatto costruito con `Object.assign` (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L15-L24)

Le due generazioni sono collegate da un **ponte a senso unico** (toggle → config) installato da `FeaturesConfigModule.forRoot()` "for backward compatibility with the deprecated FeaturesConfig" (core-libs/core/src/features-config/features-config.module.ts:L28-L52). La direttiva strutturale `*cxFeature`, che nei template è il modo più diffuso di leggere un toggle, passa ancora dal servizio legacy (core-libs/core/src/features-config/directives/feature.directive.ts:L11-L17): per questo il ponte non si può togliere.

Il capitolo copre anche il lato **stili**: un toggle può attivare regole SCSS tramite il mixin `forFeature()` e la funzione TS `useFeatureStyles()`, che insieme fanno comparire classi `cxFeat_<chiave>` sull'elemento root (core-libs/core/src/features-config/services/feature-styles.service.ts:L17-L26, core-libs/styles/scss/_features.scss:L41-L62). Il vecchio approccio per versione, `forVersion()`, è deprecato (core-libs/styles/scss/_versioning.scss:L1-L2).

Infine si guarda alla **politica di deprecazione** come emerge dal codice: tag `@deprecated` (165 occorrenze nelle librerie, tabella completa in A10 — API deprecate), interfaccia dei toggle volutamente *strict* (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L7-L11), TODO "Remove feature flag next major release." e regole ESLint dedicate.

L'elenco delle 107 chiavi, con default, descrizione e conteggi d'uso, è in A09 — Feature toggle. Questo capitolo spiega il meccanismo; l'appendice è il catalogo.

> Nota sul focus dell'OUTLINE: una **pipe** dedicata ai feature toggle allo SHA **non esiste**. Allo SHA nessuna `@Pipe` legge i feature toggle: le pipe del repo (es. `cxTranslate`, `cxUrl`, `cxDate`, `cxArgs`, `formatTimer`, `cxMultiLine`) non hanno a che fare con `FeatureToggles` (core-libs/core/src/i18n/translate.pipe.ts:L25-L28, core-libs/core/src/routing/configurable-routes/url-translation/url.pipe.ts:L11-L11,

> core-libs/core/src/i18n/date.pipe.ts:L13-L13, feature-libs/asm/core/utils/args/args.pipe.ts:L33-L33).

Capitoli collegati: la meccanica di `Config`/`ConfigChunk`/`deepMerge` è in 11 — Configurazione; i token `providedIn: 'root'` e i multi provider in 01 — Dependency injection; gli `APP_BOOTSTRAP_LISTENER` nel contesto del bootstrap in 10 — Bootstrap e inizializzazione; gli stili in generale in 38 — Stili e theming; le migrazioni in 43 — Schematics e migrazioni; il test tooling in 44 — Test tooling.

3. Come funziona passo per passo

3.1 Il catalogo: `FeatureTogglesInterface` e `defaultFeatureToggles`

Tutte le chiavi stanno in un solo file. L'interfaccia apre con un commento programmatico:

- niente index signature, così che una chiave rimossa provochi un errore di compilazione nel codice cliente: "customers using a property that was recently removed, will know they have to adapt their code" (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L7-L11);
- l'interfaccia va da L11 a L1011 e dichiara 107 proprietà `?: boolean` (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L11-L1011);
- `defaultFeatureToggles` è tipato `Required<FeatureTogglesInterface>`: il compilatore obbliga a dare un default a ogni chiave. Allo SHA sono 32 `true` e 75 `false` (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1013-L1121);
- l'ordine delle chiavi nei default non coincide con quello dell'interfaccia (es. `alignNavigationMenuWithHeader` sta a L469 nell'interfaccia e a L1016 nei default: core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L469-L469, core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1016-L1016).

Le JSDoc seguono convenzioni ricorrenti: una descrizione, spesso `Affects: <Classi>`, note `NOTE:` sulle dipendenze esterne (es. `authorizationCodeFlowByDefault` richiede un Authorization Server CCv2 "September 2025 update or higher": core-libs/core/src/features-config/feature-toggles/config/feature-toggles.

ts:L153-L161) o da altri toggle (`authorizationCodeFlowByDefaultCsrfTokenRefresh` "Only applies when `authorizationCodeFlowByDefault` is also enabled": core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L163-L172). Alcune elencano anche i file SCSS toccati (`a11yHighContrastFix`: core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L995-L1010). Non tutti i toggle riguardano la UI: `enableCartSlowNetworkResilience` attiva i fix CXSPA-10582 sul carrello e descrive cosa torna "pre-fix" quando è OFF (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L554-L583).

Il barrel `feature-toggles/index.ts` **non** esporta questo file: "don't export from './config/feature-toggles' as it contains private API" (core-libs/core/src/features-config/feature-toggles/index.ts:L7-L9). Dall'esterno si usa il tipo `FeatureToggles`, che estende l'interfaccia.

3.2 I token: due livelli, quattro token

`feature-toggles-tokens.ts` definisce una piramide a due livelli, **default** (librerie) e **root** (applicazione):

1. `DefaultFeatureTogglesChunk` e `FeatureTogglesChunk` sono `InjectionToken<FeatureToggles[]>` `providedIn: 'root'` con factory `() => []`, alimentati come multi provider (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L60-L78). La JSDoc del primo fissa la regola: "all FeatureToggles provided in libraries should be provided as `default`" (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L69-L78).
2. `DefaultFeatureToggles` unisce i chunk default con `Object.assign({}, ...chunks)`, con fallback `[]` (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L33-L43).
3. `RootFeatureToggles` fa lo stesso con i `FeatureTogglesChunk` (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L48-L58). Se due chunk hanno la stessa chiave, "last provided wins" (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.spec.ts:L58-L58).
4. `FeatureToggles` è una classe astratta `providedIn: 'root'` con `useFactory` che restituisce `Object.assign({}, inject(DefaultFeatureToggles), inject(RootFeatureToggles))`: i valori root vincono sui default, e il merge è **shallow** (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L15-L24).
5. La riga `export interface FeatureToggles extends FeatureTogglesInterface {}` usa il declaration merging di TypeScript: la classe astratta, che serve da token DI, riceve le 107 proprietà tipate (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L25-L25).
6. `FeatureToggleKey = keyof FeatureToggles` e `FeatureToggleExpression = FeatureToggleKey | \!${FeatureToggleKey}`: la negazione è un template literal type, quindi '!chiavelnesistente' non compila (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L27-L28`).

3.3 I provider

`feature-toggles-providers.ts` espone quattro helper simmetrici:

- `provideFeatureToggles(toggles = {})` → `ValueProvider` multi su `FeatureTogglesChunk`. La JSDoc dice che va fornito "in the root injector (in an eagerly loaded module)" e rimanda le librerie a `provideDefaultFeatureToggles()` (core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L16-L33).
- `provideFeatureTogglesFactory(factory)` → `FactoryProvider` multi sullo stesso token, senza `deps`: la factory usa `inject()` (core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L44-L52). Il tipo della factory è `(...props: any[]) => FeatureToggles` (core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L14-L14).

- `provideDefaultFeatureToggles` / `provideDefaultFeatureTogglesFactory` → stessi provider su `DefaultFeatureTogglesChunk`, con "CAUTION: It should be provided only in the root injector" (core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L54-L86).

3.4 `FeaturesConfigModule.forRoot()` e il ponte verso `Config.features`

`BaseCoreModule` importa `FeaturesConfigModule.forRoot()` senza argomenti, dopo `ProcessModule.forRoot()` e prima di `SiteContextModule.forRoot()` (core-libs/core/src/base-core.module.ts:L36-L38). `forRoot(defaultLevel = '3.0')` registra quattro cose (core-libs/core/src/features-config/features-config.module.ts:L28-L52):

1. `provideDefaultFeatureToggles(defaultFeatureToggles)`: il catalogo diventa il primo chunk default;
2. `...populateFeatureTogglesToFeaturesConfig`: il ponte;
3. `provideDefaultConfig({ features: { level: defaultLevel || '*' } })`: il livello legacy;
4. un `APP_BOOTSTRAP_LISTENER` che chiama `FeatureStylesService.init(compRef)` (core-libs/core/src/features-config/features-config.module.ts:L41-L49), descritto in §3.8.

Il ponte è un array di due `FactoryProvider` (core-libs/core/src/features-config/feature-toggles/populate-feature-toggles-to-features-config.ts:L18-L33):

- `provideConfigFactory(() => ({ features: { ...inject(RootFeatureToggles) } }))` → un `ConfigChunk`;
- `provideDefaultConfigFactory(() => ({ features: { ...inject(DefaultFeatureToggles) } }))` → un `DefaultConfigChunk`.

`provideConfigFactory` e `provideDefaultConfigFactory` producono multi provider su `ConfigChunk` / `DefaultConfigChunk` (core-libs/core/src/config/config-providers.ts:L37-L48, core-libs/core/src/config/config-providers.ts:L69-L79). `RootConfig` e `DefaultConfig` sono il `deepMerge` dei rispettivi chunk e `Config = deepMerge({}, DefaultConfig, RootConfig)` (core-libs/core/src/config/config-tokens.ts:L10-L21, core-libs/core/src/config/config-tokens.ts:L23-L39). `FeaturesConfig` è `@Injectable({ providedIn: 'root', useExisting: Config })` (core-libs/core/src/features-config/config/features-config.ts:L27-L31) e il file aggiunge `FeaturesConfig` a `Config` con module augmentation (core-libs/core/src/features-config/config/features-config.ts:L120-L122): iniettare `FeaturesConfig` restituisce lo stesso oggetto `Config` globale.

Il ponte va **in un solo verso**: copia i toggle nella config, mai la config nei toggle. Chi scrive `provideConfig({ features: { x: true } })` lo vede con `FeatureConfigService.isEnabled('x')` e con `*cxFeature`, ma **non** con `inject(FeatureToggles).x` (vedi §9).

3.5 Lettura legacy: `FeatureConfigService` e `isFeatureEnabled`

`FeatureConfigService` è `providedIn: 'root'`, `@deprecated - Use FeatureToggles instead`, e riceve `FeaturesConfig`, cioè il `Config`, nel costruttore (core-libs/core/src/features-config/services/feature-config.service.ts:L15-L22). Ha due metodi (core-libs/core/src/features-config/services/feature-config.service.ts:L24-L33):

- `isLevel(version)` (deprecato, "features level is no longer used") → `isFeatureLevel(config, version)`;
- `isEnabled(feature)` → `isFeatureEnabled(config, feature)`.

`isFeatureEnabled` (core-libs/core/src/features-config/utils/feature-config-utils.ts:L48-L65):

1. se `config.features` è falsy, restituisce `false` (guardia `isFeatureConfig`: core-libs/core/src/features-config/utils/feature-config-utils.ts:L11-L13);
2. toglie l'eventuale `!` e legge `config.features[key]`;

3. se il valore è una **stringa**, lo tratta come livello di versione e delega a `isFeatureLevel`; altrimenti usa `valore ?? false`;
4. se l'espressione era negata, inverte il risultato.

La firma accetta anche il letterale `'disableConfigUpdates'` oltre a `FeatureToggleExpression` (core-libs/core/src/features-config/utils/feature-config-utils.ts:L48-L51): così `ConfigurationService.emitUnifiedConfig()` legge quella chiave per decidere se fare il deep-merge della config unificata (inclusi i chunk dei moduli lazy) dentro l'oggetto `Config` globale (core-libs/core/src/config/services/configuration.service.ts:L92-L106).

`isFeatureLevel` (core-libs/core/src/features-config/utils/feature-config-utils.ts:L36-L46) supporta la negazione `'!x.y'` e restituisce `false` se `features.level` manca. Il confronto vero è nel privato `isInLevel` (core-libs/core/src/features-config/utils/feature-config-utils.ts:L15-L34): `'*'` vale sempre; altrimenti scorre le parti numeriche della versione richiesta (le parti mancanti del livello valgono 0) e alla prima differenza restituisce `livello > versione`; se tutte le parti coincidono, `true`.

3.6 Lettura nei template: `*cxFeature`

`FeatureDirective` (selettore `[cxFeature]`) inietta `TemplateRef`, `ViewContainerRef` e il `FeatureConfigService` deprecato (core-libs/core/src/features-config/directives/feature.directive.ts:L11-L17). Il setter dell'input (core-libs/core/src/features-config/directives/feature.directive.ts:L19-L29):

- toggle abilitato e nessuna vista → `createEmbeddedView(templateRef)` e `hasView = true`;
- toggle disabilitato e vista presente → `viewContainer.clear()` e `hasView = false`.

La direttiva non si sottoscrive a nulla e rivaluta solo quando cambia il valore dell'input. Il pattern tipico è la coppia positivo/negato, vecchia UI contro nuova, come in `ProductImageZoomViewComponent` (feature-libs/product/image-zoom/components/product-image-zoom/product-image-zoom-view/product-image-zoom-view.component.html:L15-L15, feature-libs/product/image-zoom/components/product-image-zoom/product-image-zoom-view/product-image-zoom-view.component.html:L35-L35). Allo SHA ci sono 165 occorrenze di `*cxFeature=` in 62 file `.html`, 67 delle quali negate; `cxFeatureLevel` non compare in nessun template, solo nella direttiva e nel mock core-libs/storefront/shared/test/mock-feature-level-directive.ts:L9-L9 (conteggi del dossier, F50).

`FeatureLevelDirective` (`[cxFeatureLevel]`) ha la stessa logica con `isLevel(level.toString())` ed è `@deprecated Unused directive` (core-libs/core/src/features-config/directives/feature-level.directive.ts:L10-L31). Entrambe le direttive non dichiarano `standalone`, che in Angular 21 vale `true` per default (`standalone: directiveDefinition.standalone ?? true`: angular:packages/core/src/render3/definition.ts:L637-L637; JSDoc dell'opzione: angular:packages/core/src/metadata/directives.ts:L335-L337). Per questo `FeaturesConfigModule` le mette in `imports` ed `exports` invece che in `declarations` (core-libs/core/src/features-config/features-config.module.ts:L23-L27).

3.7 Lettura in TypeScript: `inject(FeatureToggles)`

Il pattern raccomandato è un campo `private` (`private featureToggles = inject(FeatureToggles)`) letto come proprietà: `this.featureToggles.a11yKeyboardAccessibleZoom` (feature-libs/product/image-zoom/components/product-image-zoom/product-image-zoom-view/product-image-zoom-view.component.ts:L92-L92, feature-libs/product/image-zoom/components/product-image-zoom/product-image-zoom-view/product-image-zoom-view.component.ts:L234-L234). Il dossier conta 126 occorrenze di `inject(FeatureToggles)` in 117 file non-spec e 180 accessi `featureToggles.<chiave>` in 99 file. Fuori da `features-config`, a runtime `FeatureConfigService` è iniettato solo da `CxApiService`, come campo `public` opzionale (core-libs/

storefront/cms-structure/page/component/services/cx-api.service.ts:L46-L46). Le altre occorrenze sono dati delle migrazioni schematics, regole ESLint e commenti.

I toggle si leggono anche **dentro le factory di config di default**. `defaultAuthConfigFactory` destruttura `authorizationCodeFlowByDefault`, `asyncAuthConfigInitializer` e `oauthCallbackPage` da `inject(FeatureToggles)` (core-libs/core/src/auth/user-auth/config/default-auth-config.ts:L76-L83) ed è registrata con `provideDefaultConfigFactory(defaultAuthConfigFactory)` in `UserAuthModule` (core-libs/core/src/auth/user-auth/user-auth.module.ts:L106-L106). Qui si usa `FeatureToggles` e non `FeatureConfigService` per evitare un ciclo di DI: `FeatureConfigService` dipende da `Config`, che a sua volta dipende da tutti i `DefaultConfigChunk`, compresa questa factory. La regola ESLint lo dice esplicitamente: `inject(FeatureToggles)` "is preferred over `inject(FeatureConfigService)` inside `provideDefaultConfigFactory()` to avoid circular DI" (tools/eslint-rules/rules/feature-toggles-must-be-private.ts:L23-L26). Il flusso auth completo è in 22 — Autenticazione.

3.8 Stili per feature: `useFeatureStyles` + `forFeature` + `FeatureStylesService`

Un toggle può attivare regole CSS senza toccare il DOM del componente. I pezzi sono tre.

SCSS. `_core.scss` importa prima `features` e poi `versioning` (core-libs/styles/scss/_core.scss:L1-L2). `_features.scss` definisce il prefisso `$CSS_FEATURE_FLAG_PREFIX: 'cxFeat_'` e la funzione `getFeatureCssClass` (core-libs/styles/scss/_features.scss:L3-L14). Il mixin `forFeature($feature, $classTarget: 'ancestorSelector')`:

- valida i parametri con `@error`: `$feature` deve essere una stringa, `$classTarget` deve valere `'ancestorSelector'` o `'currentSelector'` (core-libs/styles/scss/_features.scss:L42-L49);
- con `ancestorSelector` emette `@at-root .cxFeat_<f> & { ... }`, cioè la classe sta su un antenato; con `currentSelector` emette `@at-root &.cxFeat_<f> { ... }`, cioè la classe sta sullo stesso elemento (core-libs/styles/scss/_features.scss:L51-L61). Il secondo caso va usato "ONLY in one edge case", per gli stili dell'elemento root (core-libs/styles/scss/_features.scss:L38-L40). L'unico uso di produzione è in `root.scss`, dentro `:root`, per `a11yPreventWindowsHighContrastOverride` (core-libs/styles/scss/root.scss:L36-L44).

TS, lato componente. `useFeatureStyles(feature)` chiama `assertInInjectionContext`, inietta `FeatureStylesService` e `DestroyRef`, registra l'uso e lo cancella in `destroyRef.onDestroy` (core-libs/core/src/features-config/utils/use-feature-styles.ts:L32-L40). La JSDoc impone di chiamarla nel costruttore di **ogni** componente il cui SCSS usa `forFeature`, altrimenti gli stili "MIGHT NOT be activated EVEN if the flag is enabled" (core-libs/core/src/features-config/utils/use-feature-styles.ts:L11-L31). Fuori da un injection context, `assertInInjectionContext` lancia `RuntimeError` `MISSING_INJECTION_CONTEXT` (angular:packages/core/src/di/contextual.ts:L77-L88).

TS, lato servizio. `FeatureStylesService` (core-libs/core/src/features-config/services/feature-styles.service.ts:L17-L26):

1. legge `FeatureToggles` (non `FeaturesConfig`) e crea un `Renderer2` con `createRenderer(null, null)` (core-libs/core/src/features-config/services/feature-styles.service.ts:L27-L41);
2. tiene `usagesCounter: Map<string, number>`: quando un contatore passa a >0 aggiunge la classe, quando torna a 0 la toglie (core-libs/core/src/features-config/services/feature-styles.service.ts:L50-L56);
3. `registerUsage` aggiunge la classe solo se il flag è abilitato e il contatore era 0, poi incrementa il contatore **anche se il flag è spento** (core-libs/core/src/features-config/services/feature-styles.service.ts:L89-L95);
4. `unregisterUsage` in dev mode avvisa se il contatore è già 0, toglie la classe se il flag è abilitato e il contatore vale 1, poi decrementa con `Math.max(..., 0)` (core-libs/core/src/features-config/services/

feature-styles.service.ts:L103-L115);

5. addClass/removeClass non fanno nulla se rootElement non è ancora impostato o se getCssClass restituisce undefined (core-libs/core/src/features-config/services/feature-styles.service.ts:L130-L150). getCssClass restituisce cxFeat_<feature> solo se il flag è truthy (core-libs/core/src/features-config/services/feature-styles.service.ts:L158-L162), e isEnabled è !!this.featureToggles[feature] (core-libs/core/src/features-config/services/feature-styles.service.ts:L120-L122).

Bootstrap. Il servizio non conosce l'elemento root finché non riceve init. Angular chiama gli APP_BOOTSTRAP_LISTENER in _loadComponent, **dopo** il primo tick() del componente root, leggendoli dall'injector in modo lazy "to prevent DI cycles" (angular:packages/core/src/application/application_ref.ts:L775-L794; token: angular:packages/core/src/application/application_ref.ts:L64-L66). Il listener di forRoot() passa il ComponentRef a init, che salva rootComponent.location.nativeElement e aggiunge le classi per tutti i contatori >0 già registrati (core-libs/core/src/features-config/services/feature-styles.service.ts:L65-L77). Senza questo recupero si perderebbero le registrazioni fatte nei costruttori dei componenti creati prima dell'invocazione dei listener (il commento del sorgente cita il costruttore del root component), che arrivano prima dell'init. DA VERIFICARE: in quale fase esatta (creazione del root component o primo tick()) vengono costruiti i componenti figli come StorefrontComponent non è stato tracciato nel renderer di Angular; per il meccanismo conta solo che avvenga prima dei listener.

StorefrontComponent registra così sei stili globali nel costruttore (core-libs/storefront/layout/main/storefront.component.ts:L118-L123). Per uno di questi la classe sull'elemento root dell'app non basta: le regole stanno su :root, cioè <html>. Per questo ngOnInit aggiunge a mano cxFeat_a11yPreventWindowsHighContrastOverride a document.documentElement ("TODO: Required to use feature flag with root styles": core-libs/storefront/layout/main/storefront.component.ts:L141-L147).

Il dossier conta 56 chiamate a useFeatureStyles(in 44 file TS non-spec (esclusa features-config) e 70 @include forFeature(in 40 file .scss di produzione (78 in 41 contando lo spec core-libs/styles/test/features.spec.scss) (F73).

3.9 Il vecchio approccio SCSS: _versioning.scss

_versioning.scss apre con "🚨 CAUTION": forVersion($level) è deprecato e sostituito da forFeature($featureName) (core-libs/styles/scss/_versioning.scss:L1-L2). Il file contiene:

- le versioni interne $_fullVersion: (major: 221121, minor: 22, patch: 0) e $_majorVersion: 2211 (core-libs/styles/scss/_versioning.scss:L29-L37);
- le variabili di opt-in del cliente, $styleVersion: $_majorVersion !default e $useLatestStyles: false !default (core-libs/styles/scss/_versioning.scss:L41-L46);
- il mixin forVersion($from, $to: 0), @deprecated since 2211.20, che emette il contenuto solo se $from <= $_fullVersion e la versione è stabile e valida, oppure è richiesta come breaking change (core-libs/styles/scss/_versioning.scss:L63-L77);
- useBreakingChanges(), vera se $useLatestStyles è attivo o $styleVersion > $_majorVersion (core-libs/styles/scss/_versioning.scss:L228-L231).

forVersion non ha usi di produzione: compare solo nel commento d'esempio (core-libs/styles/scss/_versioning.scss:L18-L18) e nella utility di test (core-libs/styles/test/versioning-test-util.scss:L6-L6). La storefrontapp imposta comunque $useLatestStyles: true; (projects/storefrontapp/src/styles-config.scss:L2-L2).

3.10 Chi fornisce i toggle nell'applicazione

- **App demo**: `provideFeatureTogglesFactory` restituisce un oggetto tipato `Required<FeatureToggles>`, quindi aggiungere un toggle alla libreria obbliga ad aggiornare anche l'app (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L297-L301). La regola `no-storefrontapp-false-feature-toggles` impone che tutti i valori siano `true`; un `false` è ammesso solo con un eslint-disable che citi un ticket CX-SPA (tools/eslint-rules/rules/no-storefrontapp-false-feature-toggles.ts:L33-L45, projects/storefrontapp/eslint.config.mjs:L26-L28).
- **App nuova (`ng add`)**: lo schematic genera `provideFeatureToggles({...})` con **tutte** le chiavi di `defaultFeatureToggles` a `true` (core-libs/schematics/src/add-spartacus/spartacus-feature-toggles.ts:L77-L93). Per non dipendere a runtime da `@spartacus/core`, lo schematic legge una copia del file TS del core (core-libs/schematics/src/add-spartacus/spartacus-feature-toggles.ts:L95-L113). La copia è fatta in pre-build dallo script `copy-feature-toggles` (core-libs/schematics/package.json:L16-L16) con un semplice `fs.copyFileSync` verso `./src/feature-toggles.copied-from-core-lib.ts` (core-libs/schematics/copy-feature-toggles.js:L5-L10); il path di lettura è la costante `FEATURE_TOGGLES_COPIED_FROM_CORE_LIB_PATH` (core-libs/schematics/src/shared/constants.ts:L1176-L1177). Gli schematics sono trattati in 43 — Schematics e migrazioni.
- **Test con `TestConfigModule`**: fornisce di proposito toggle ad alta priorità con `provideFeatureTogglesFactory(() => inject(TEST_CONFIG)?.features)`, disattivando la regola di lint per quella riga (core-libs/core/src/config/test-config.module.ts:L94-L98).

3.11 Strumenti di test

`provideMockFeatureToggles(initial)` crea un `MockFeatureTogglesController` e lo lega **come stesso oggetto** a `MockFeatureTogglesController`, `FeatureToggles`, `RootFeatureToggles`, `DefaultFeatureToggles` e `FeatureTogglesChunk` (multi), e lo inserisce anche in un `ConfigChunk` (`features: controller`) tramite `provideConfigFactory` (core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L150-L204). `Config.features`, però, nasce dal deep-merge dei chunk e non condivide il riferimento: per questo il mock sostituisce anche `FeatureConfigService` (core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L121-L125). Il controller è un oggetto che fa sia da toggle sia da API di controllo: `set` assegna una chiave, `reset` cancella tutto tranne `set`/`reset` e poi applica `Object.assign` (core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L95-L119). Viene creato da capo a ogni setup di TestBed, quindi le mutazioni non passano da un test all'altro (core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L154-L159).

Il mock sostituisce anche `FeatureConfigService` con un `MockFeatureConfigService` che legge il controller (core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L206-L216). Senza questa sostituzione `*cxFeature` leggerebbe lo snapshot `Config.features`, già deep-merged al bootstrap, e non vedrebbe le chiamate a `set(...)`. `MockFeatureConfigService` riusa `isFeatureEnabled`/`isFeatureLevel` passando un finto `Config { features: this.toggles }` (core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L132-L148).

Il testing **non** è un entry point pubblicato: le librerie lo raggiungono tramite alias nei tsconfig o nella config vitest, per esempio `@spartacus/core/testing/feature-toggles` in storefront (core-libs/storefront/tsconfig.spec.json:L17-L19) e `@spartacus/core/testing/mock-feature-toggles` in checkout (feature-libs/checkout/vitest.config.ts:L26-L26). `provideMockFeatureToggles` compare in 87 file `.spec.ts` (F95). Dettagli in 44 — Test tooling.

3.12 Deprecazioni: cosa dice il codice

- **Conteggi.** `@deprecated` nei `.ts` non-spec delle librerie, esclusi i path con `schematics`, `testing` e `mock`: 165 occorrenze in 124 file, uguale al totale di A10 (`docs/spartacus-book/appendici/A10-deprecated.md:L11-L30`). La distribuzione è molto sbilanciata: `@spartacus/epd-visualization` ne ha 91, `@spartacus/core` 14. Delle 14 di core, 10 stanno nella sola cartella `features-config` (F109).
- **Formati.** Non sono uniformi: con versione (`@deprecated since 2211.22 - should not be a public API`: `core-libs/core/src/config/config-initializer/config-initializer.module.ts:L33-L33`; `@deprecated since 2211.32. Use initOnce() ...`: `core-libs/core/src/site-context/services/site-context-routes-handler.ts:L51-L51`), con alternativa e senza versione (`@deprecated - Use FeatureToggles instead`), oppure in un commento `//` con una scadenza ("will be removed in 12 months": `core-libs/core/src/cms/facade/page-meta.service.ts:L39-L39`).
- **Da token a toggle.** `USE_AUTHORIZATION_CODE_FLOW_BY_DEFAULT` è "@deprecated since 221121.1 Please use the `authorizationCodeFlowByDefault` feature toggle instead" (`core-libs/core/src/auth/user-auth/config/default-auth-config.ts:L11-L19`). Il provider legacy `provideAuthorizationCodeFlowByDefault(enable)` chiama `inject(FeatureToggles)` nel proprio corpo e usa `authorizationCodeFlowByDefault ?? enable` (`core-libs/core/src/auth/user-auth/config/default-auth-config.ts:L37-L46`).
- **Fine vita dei toggle.** Il codice da rimuovere è segnato con TODO "Remove feature flag next major release.", di solito con un ticket CXSPA: 23 occorrenze in 14 file ts/html/scss non-spec (F111), per esempio `core-libs/storefront/cms-components/product/product-intro/product-intro.component.html:L6-L6`. La "lifespan" di ogni toggle è "defined in the official docs" (`core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L16-L19`). DA VERIFICARE: nel repo non c'è una policy di rimozione codificata oltre a questi TODO; la documentazione ufficiale non è stata verificata.
- **Lint come politica.** `feature-toggles-must-be-private` richiede che `FeatureToggles` sia iniettato `private`: la rimozione di un toggle, "the normal end-of-life of a toggle", non deve diventare un breaking change TypeScript per chi lo referenzia da una sottoclasse (`tools/eslint-rules/rules/feature-toggles-must-be-private.ts:L11-L26`). Questa regola e `feature-config-service-must-be-private` sono `error` su `**/*.ts` (`eslint.config.mjs:L255-L256`). Nei `**/*.module.ts` delle librerie, `use-provide-default-feature-toggles(-factory)` sono `error` (`eslint.config.mjs:L237-L238`, messaggio: `tools/eslint-rules/rules/use-provide-default-feature-toggles.ts:L34-L35`); la storefrontapp le spegne (`projects/storefrontapp/eslint.config.mjs:L14-L15`).

---

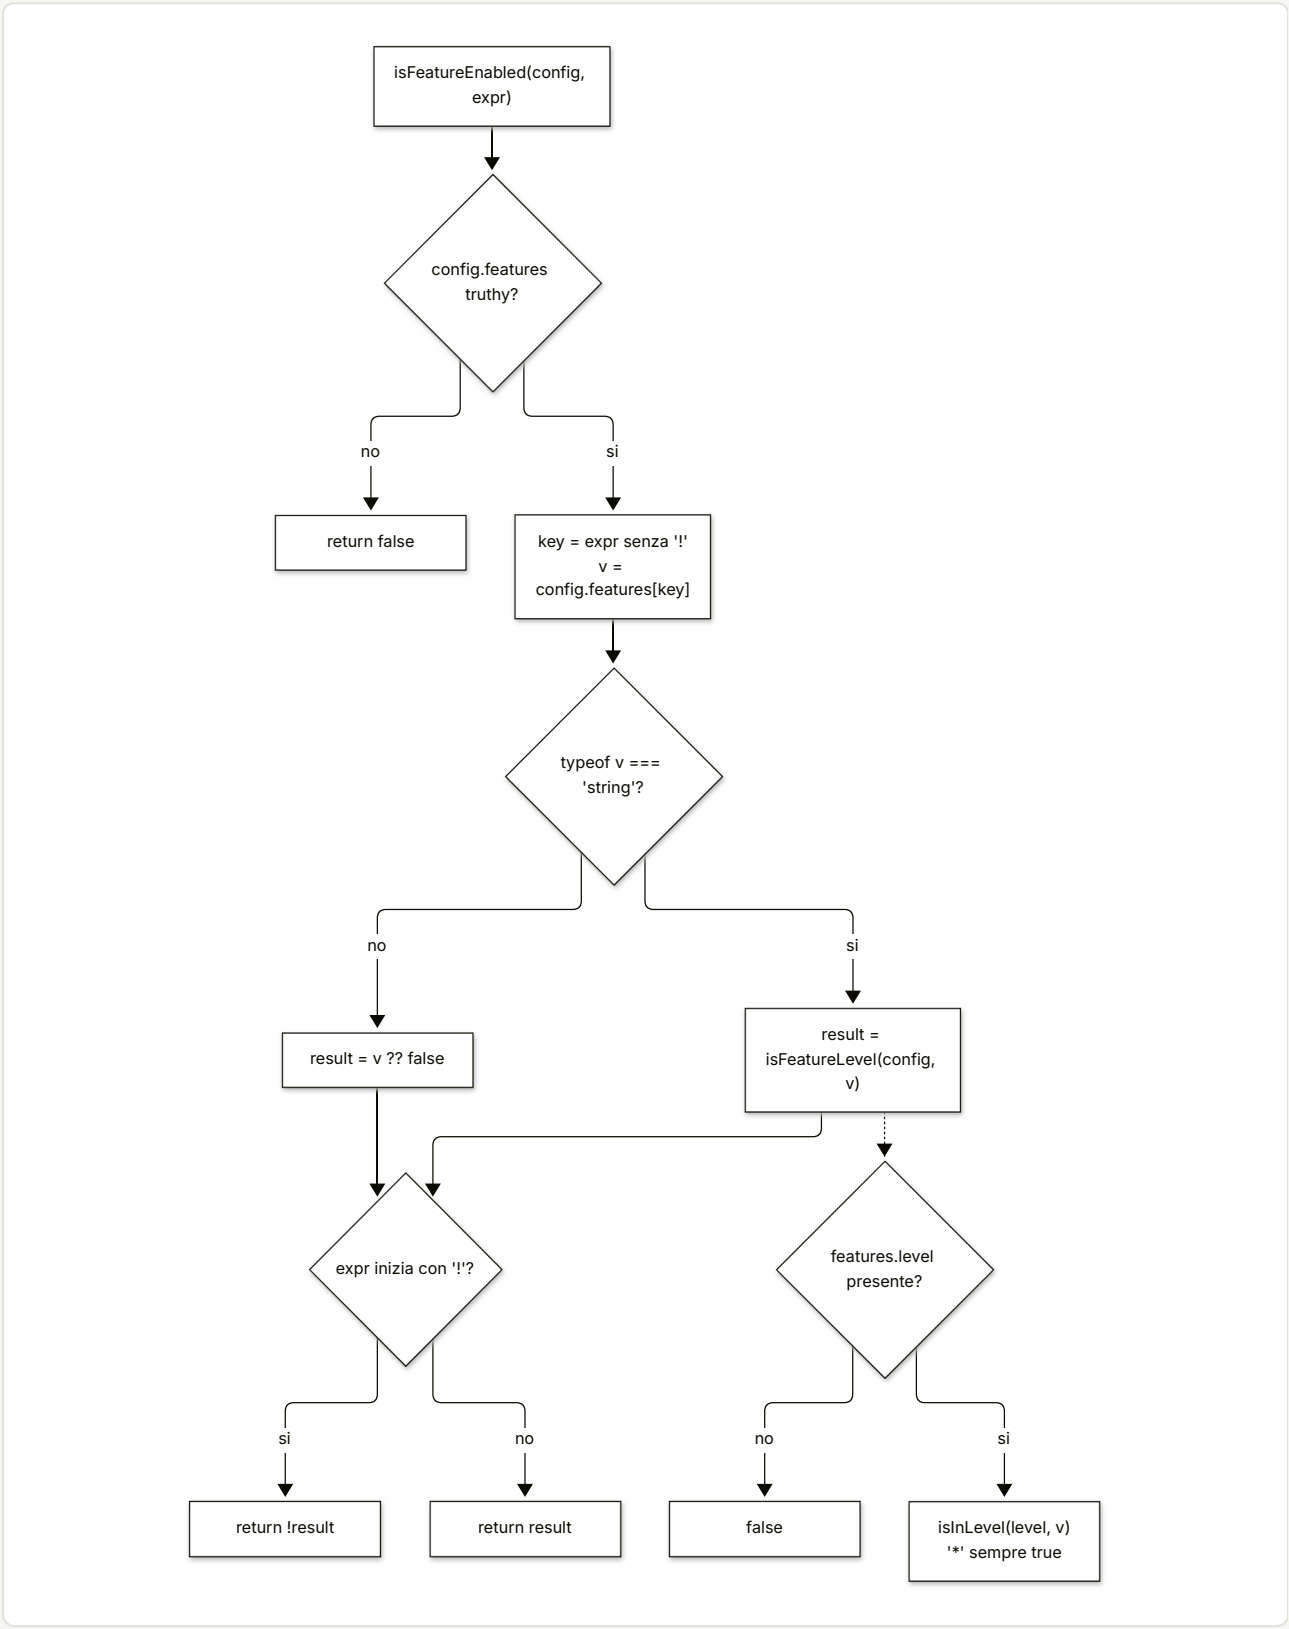
4. Diagrammi

4.1 Costruzione di `FeatureToggles` e ponte verso `Config.features`

■ **TAVOLA 42.1** diagramma a tutta pagina, in fondo al capitolo

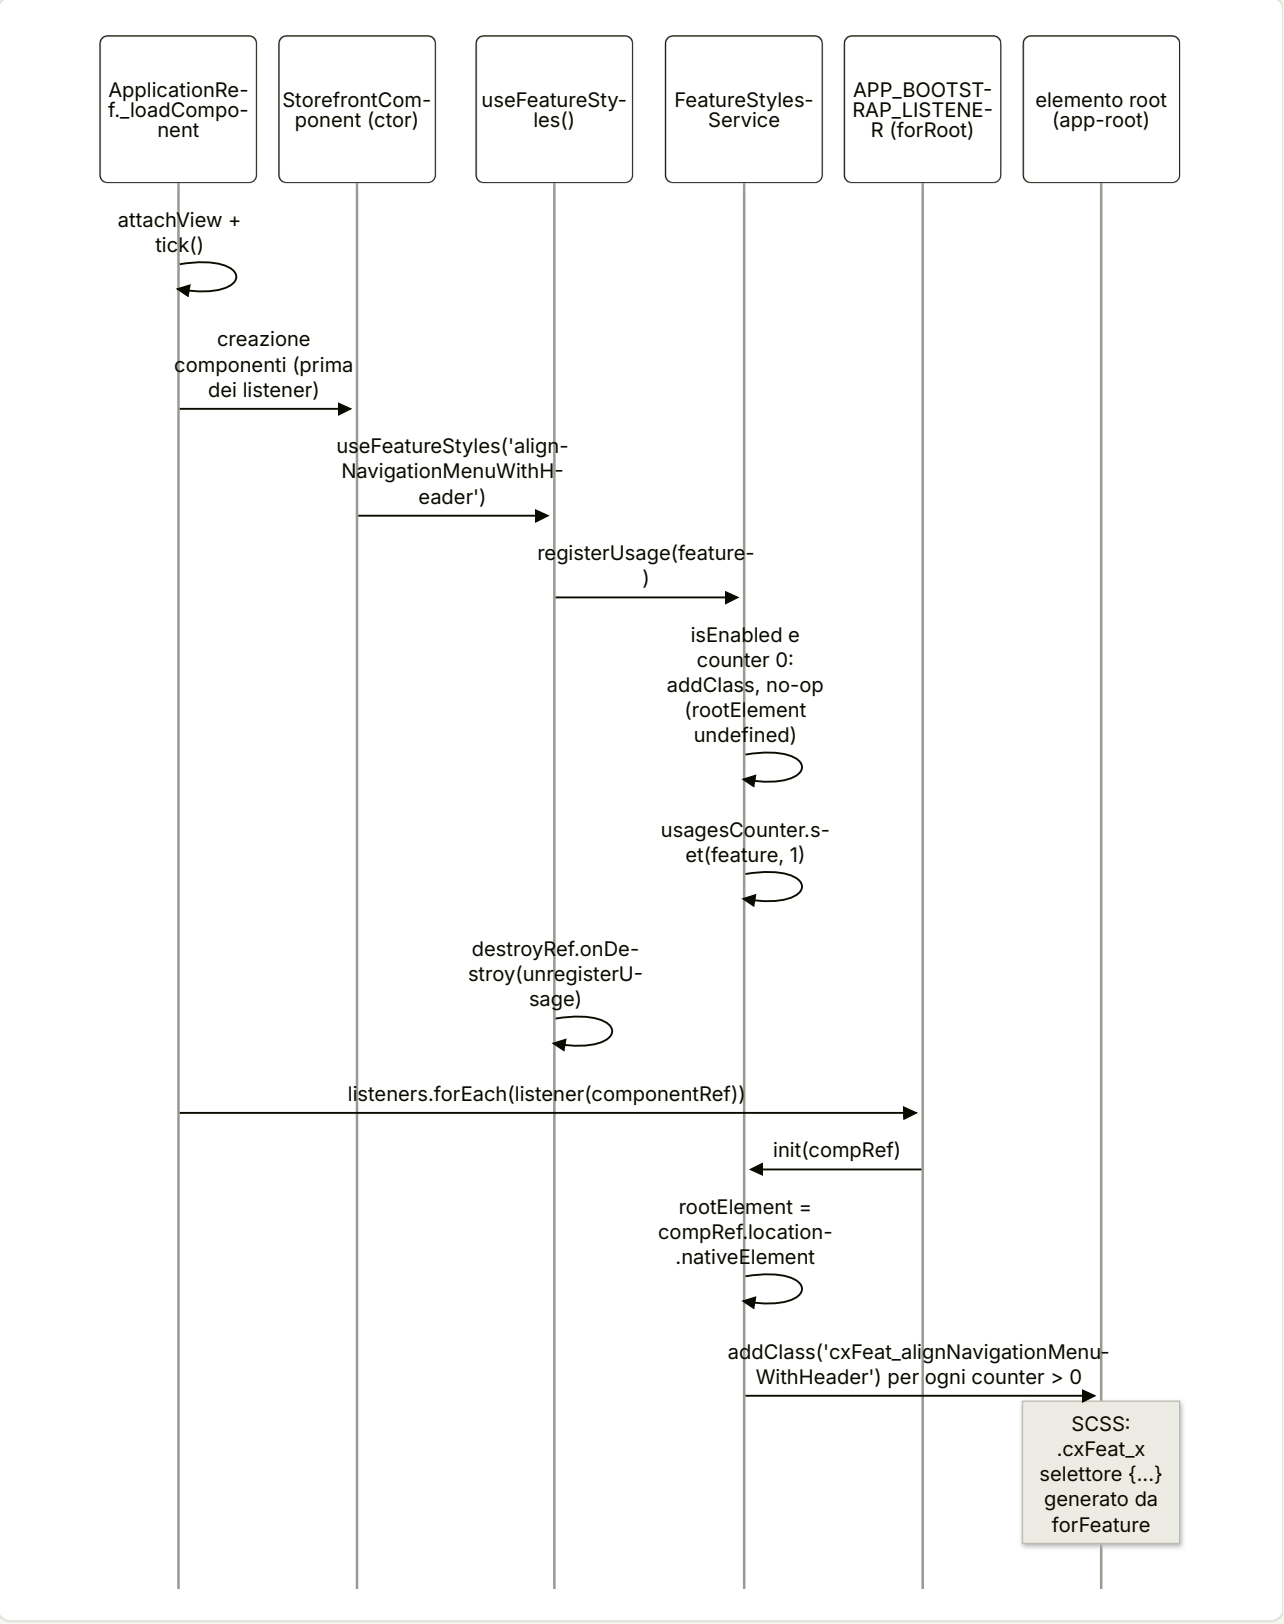
Riferimenti: chunk e token `core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L15-L78`; ponte `core-libs/core/src/features-config/feature-toggles/populate-feature-toggles-to-features-config.ts:L18-L33`; `Config` `core-libs/core/src/config/config-tokens.ts:L10-L39`; `useExisting` `core-libs/core/src/features-config/config/features-config.ts:L27-L31`. Non c'è nessuna freccia da `Config` verso `FeatureToggles`: il ponte è a senso unico.

4.2 Valutazione di un'espressione legacy (`isFeatureEnabled`)



Riferimenti: `core-libs/core/src/features-config/utils/feature-config-utils.ts:L11-L65`.

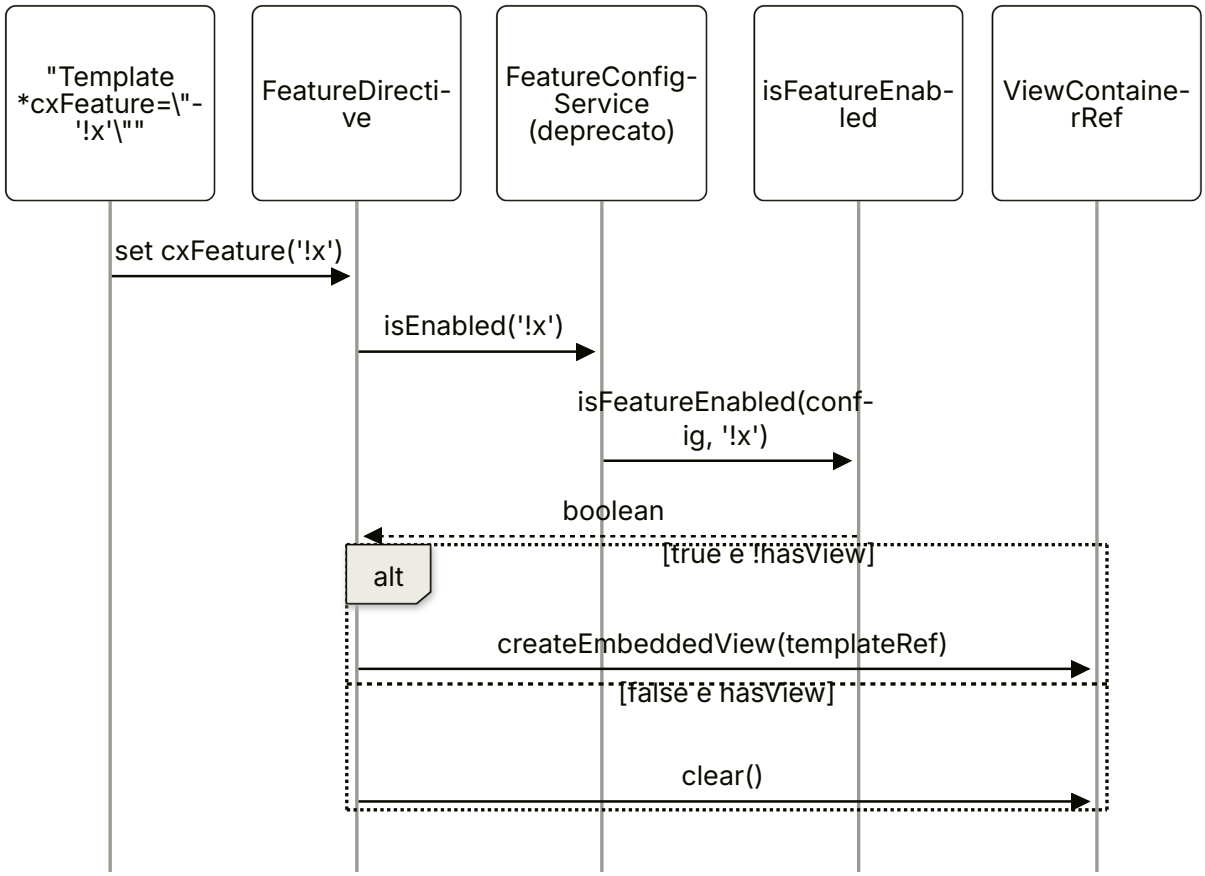
4.3 Stili per feature durante il bootstrap



Riferimenti: angular:packages/core/src/application/application_ref.ts:L775-L794; core-libs/storefront/layout/main/storefront.component.ts:L118-L123; core-libs/core/src/features-config/utils/use-feature-styles.ts:L32-L40; core-libs/core/src/features-config/services/feature-styles.service.ts:L65-L95;

core-libs/core/src/features-config/services/feature-styles.service.ts:L130-L136; core-libs/core/src/features-config/features-config.module.ts:L41-L49; core-libs/styles/scss/_features.scss:L51-L56.

4.4 `*cxFeature` nel template



Riferimenti: core-libs/core/src/features-config/directives/feature.directive.ts:L19-L29; core-libs/core/src/features-config/services/feature-config.service.ts:L31-L33.

5. Estratti di codice reale

Il token principale e il tipo dell'espressione — core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L15-L28

```ts
@Injectable({
  providedIn: 'root',
  useFactory: () =>
    Object.assign(
      {},
      inject(DefaultFeatureToggles),
      inject(RootFeatureToggles)
    ),
```

```
})
export abstract class FeatureToggles {}
export interface FeatureToggles extends FeatureTogglesInterface {}

export type FeatureToggleKey = keyof FeatureToggles;
export type FeatureToggleExpression = FeatureToggleKey | `!${FeatureToggleKey}`;
```

Interfaccia strict per scelta — core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L7-L11

```ts
// Let's NOT add here any wildcard property like
//  `[key: string]: boolean | undefined;`
// We want this interface to be STRICT and cause a compilation error when a removed property is used.
// Thanks to that, customers using a property that was recently removed, will know they have to adapt
their code.
export interface FeatureTogglesInterface {
```

Provider per l'applicazione — core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L25-L33

```ts
export function provideFeatureToggles(
  toggles: FeatureToggles = {}
): ValueProvider {
  return {
    provide: FeatureTogglesChunk,
    useValue: toggles,
    multi: true,
  };
}
```

Il ponte verso la config legacy — core-libs/core/src/features-config/feature-toggles/populate-feature-toggles-to-features-config.ts:L18-L33

```ts
export const populateFeatureTogglesToFeaturesConfig: FactoryProvider[] = [
  // Copies RootFeatureToggles to RootConfig
  provideConfigFactory(() => {
    const flags = inject(RootFeatureToggles);
    return { features: { ...flags } };
  }),

  // Copies DefaultFeatureToggles to DefaultFeaturesConfig
  provideDefaultConfigFactory(() => {
    const flags = inject(DefaultFeatureToggles);
    return { features: { ...flags } };
  }),
];
```

forRoot() — core-libs/core/src/features-config/features-config.module.ts:L28-L52

```ts
  static forRoot(
    defaultLevel = '3.0'
  ): ModuleWithProviders<FeaturesConfigModule> {
    return {
      ngModule: FeaturesConfigModule,
      providers: [
        provideDefaultFeatureToggles(defaultFeatureToggles),
        ...populateFeatureTogglesToFeaturesConfig, // for backward compatibility with the deprecated
FeaturesConfig
        provideDefaultConfig(<FeaturesConfig>{
          features: {
            level: defaultLevel || '*',
          },
        }),
        {
          provide: APP_BOOTSTRAP_LISTENER,
          multi: true,
          useFactory: (): ((compRef: ComponentRef<any>) => void) => {
            const featureStylesService = inject(FeatureStylesService);
            return (compRef: ComponentRef<any>) =>
              featureStylesService.init(compRef);
          },
        },
      ],
    };
  }
```

Valutazione legacy — core-libs/core/src/features-config/utils/feature-config-utils.ts:L48-L65

```ts
export function isFeatureEnabled(
  config: Config,
  feature: FeatureToggleExpression | 'disableConfigUpdates'
): boolean {
  if (isFeatureConfig(config)) {
    const featureConfig = feature.startsWith('!')
      ? config.features[feature.substring(1)]
      : config.features[feature];

    const result =
      typeof featureConfig === 'string'
        ? isFeatureLevel(config, featureConfig)
        : (featureConfig ?? false);

    return feature.startsWith('!') ? !result : result;
  }
  return false;
}
```

La direttiva strutturale — core-libs/core/src/features-config/directives/feature.directive.ts:L19-L29

```ts
  private hasView = false;

  @Input() set cxFeature(feature: FeatureToggleExpression) {
    if (this.featureConfig.isEnabled(feature) && !this.hasView) {
      this.viewContainer.createEmbeddedView(this.templateRef);
      this.hasView = true;
    } else if (!this.featureConfig.isEnabled(feature) && this.hasView) {
      this.viewContainer.clear();
      this.hasView = false;
    }
  }
```

Registrazione d'uso degli stili — core-libs/core/src/features-config/services/feature-styles.service.ts:L65-L95

```ts
  init(rootComponent: ComponentRef<any>): void {
    this.rootElement = rootComponent.location.nativeElement;

    // Handle edge-case:
    // Add classes for all features that were used (called `registerUsage()`) before `init()` was
invoked.
    // (e.g. it's the case when `registerUsage` was called in the constructor of the root component,
    //       which happens before the hook APP_BOOTSTRAP_LISTENER is invoked by Angular, therefore
before `init` is invoked.)
    for (const [feature, count] of this.usagesCounter.entries()) {
      if (count > 0) {
        this.addClass(feature as FeatureToggleKey);
      }
    }
  }
  // ...
  registerUsage(feature: FeatureToggleKey): void {
    const currentCounter = this.usagesCounter.get(feature) ?? 0;
    if (this.isEnabled(feature) && currentCounter === 0) {
      this.addClass(feature);
    }
    this.usagesCounter.set(feature, currentCounter + 1);
  }
```

useFeatureStyles — core-libs/core/src/features-config/utils/use-feature-styles.ts:L32-L40

```ts
export function useFeatureStyles(feature: FeatureToggleKey): void {
  assertInInjectionContext(useFeatureStyles);

  const featureStylesService = inject(FeatureStylesService);
  const destroyRef = inject(DestroyRef);
```

```
  featureStylesService.registerUsage(feature);
  destroyRef.onDestroy(() => featureStylesService.unregisterUsage(feature));
}
```

Il mixin SCSS — core-libs/styles/scss/_features.scss:L41-L62

```scss
@mixin forFeature($feature, $classTarget: 'ancestorSelector') {
  // Validate params
  @if (type-of($feature) != 'string') {
    @error "forFeature: $feature param must be a string, but #{type-of($feature)} was provided.";
  }
  @if (not index(('ancestorSelector', 'currentSelector'), $classTarget)) {
    @error "forFeature: $classTarget must be either 'ancestorSelector' or 'currentSelector', but #
{$classTarget} was provided.";
  }
  // Validate params end

  $featureClass: getFeatureCssClass($feature);
  @if ($classTarget == 'ancestorSelector') {
    @at-root .#{$featureClass} & {
      @content;
    }
  }
  @if ($classTarget == 'currentSelector') {
    @at-root &.#{$featureClass} {
      @content;
    }
  }
}
```

Coppia TS + SCSS in un componente reale — feature-libs/product/image-zoom/components/product-image-zoom/product-image-zoom-view/product-image-zoom-view.component.ts:L181-L188 e feature-libs/product/image-zoom/styles/_product-image-zoom-view.scss:L14-L19

```ts
  constructor(
    protected currentProductService: CurrentProductService,
    protected renderer: Renderer2,
    protected cdRef: ChangeDetectorRef,
    protected breakpointService: BreakpointService
  ) {
    useFeatureStyles('a11yKeyboardAccessibleZoom');
  }
```

```scss
      // TODO: (CXSPA-7492) - Remove feature flag next major release.
      @include forFeature('a11yKeyboardAccessibleZoom') {
        cx-media {
```

```
          display: unset;
        }
      }
```

Workaround per gli stili su `:root` — core-libs/storefront/layout/main/storefront.component.ts:L141-L147

```ts
    // TODO: Required to use feature flag with root styles.
    //       Remove this entire block once the a11yPreventWindowsHighContrastOverride feature flag is removed
    if (this.featureToggles.a11yPreventWindowsHighContrastOverride) {
      this.document?.documentElement.classList.add(
        'cxFeat_a11yPreventWindowsHighContrastOverride'
      );
    }
```

Lo schematic accende tutto — core-libs/schematics/src/add-spartacus/spartacus-feature-toggles.ts:L80-L93

```ts
function createFeatureTogglesProvider(): string {
  const defaultFeatureToggles = getDefaultFeatureToggles();

  //for each key in `defaultFeatureToggles` map it to a key with value true
  const featureTogglesAllEnabled: Record<string, boolean> = Object.keys(
    defaultFeatureToggles
  ).reduce((acc, key) => ({ ...acc, [key]: true }), {});
  const featureTogglesString = JSON.stringify(
    featureTogglesAllEnabled,
    null,
    2
  );
  return `provideFeatureToggles(${featureTogglesString})`;
}
```

Il mock dei test sostituisce anche il servizio legacy — core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L206-L216

```ts
    // Override `FeatureConfigService` (used by the `*cxFeature` directive
    // and any other `isEnabled()` consumer) so it queries our mutable
    // controller directly. Otherwise the directive would read from the
    // immutable, deep-merged `Config.features` snapshot built at bootstrap
    // and would NOT see runtime mutations done via `controller.set(...)`.
    {
      provide: FeatureConfigService,
      useFactory: (c: MockFeatureTogglesController) =>
        new MockFeatureConfigService(c as unknown as Record<string, unknown>),
      deps: [MockFeatureTogglesController],
    },
```

6. Configurazione

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
`FeatureToggles.<chiave>` (107 chiavi, catalogo in A09)	`boolean`	da `defaultFeatureToggles`: 32 `true` / 75 `false`	interfaccia `core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L11-L1011`; default `core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1013-L1121`	`inject(FeatureToggles)`; `FeatureConfigService.isEnabled` / `*cxFeature` tramite il ponte; `FeatureStylesService` (`core-libs/core/src/features-config/services/feature-styles.service.ts:L120-L122`)
`features.<chiave>` (legacy)	`string | boolean | undefined`	copia dei toggle tramite il ponte	`core-libs/core/src/features-config/config/features-config.ts:L72-L88`; ponte `core-libs/core/src/features-config/feature-toggles/populate-feature-toggles-to-features-config.ts:L18-L33`	`isFeatureEnabled` (`core-libs/core/src/features-config/utils/feature-config-utils.ts:L48-L65`)
`features.level` (deprecata)	`string`	`'3.0'` (default di `forRoot`), `'*'` se l'argomento è falsy	`core-libs/core/src/features-config/config/features-config.ts:L49-L70`; `core-libs/core/src/features-config/features-config.module.ts:L28-L40`	`isFeatureLevel` (`core-libs/core/src/features-config/utils/feature-config-utils.ts:L36-L46`), anche quando un toggle legacy ha valore stringa (`core-libs/core/src/features-config/utils/feature-config-utils.ts:L57-L60`)
`features.consignmentTracking`	`boolean`	`'1.2'` (stringa, fornita da `OrderDetailsModule` con `provideDefaultConfig`, interpretata come livello: `true` con `level '3.0'`; `feature-libs/order/components/order-details/order-details.module.ts:L173-L175`). La chiave non è in `FeatureTogglesInterface`: arriva solo dalla config legacy	`core-libs/core/src/features-config/config/features-config.ts:L90-L99`	`*cxFeature` in `OrderConsignedEntriesComponent` (`feature-libs/order/components/order-details/order-detail-items/order-consigned-entries/order-consigned-entries.component.html:L19-L19`)
`features.disableConfigUpdates` (deprecata)	`boolean`	non definita → `false` (`?? false`)	`core-libs/core/src/features-config/config/features-config.ts:L101-L116`	`core-libs/core/src/config/services/configuration.service.ts:L92-L106`
`$styleVersion` (SCSS, deprecata)	numero di versione	`$_majorVersion` (2211) `!default`	`core-libs/styles/scss/_versioning.scss:L41-L41`	`useBreakingChanges()` (`core-libs/styles/scss/_versioning.scss:L228-L231`)

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
`$useLatestStyles` (SCSS, deprecata)	bool	`false !default;` storefrontapp `true`	core-libs/styles/scss/_versioning.scss:L46-L46; projects/storefrontapp/src/styles-config.scss:L2-L2	core-libs/styles/scss/_versioning.scss:L228-L231
`$CSS_FEATURE_FLAG_PREFIX` (SCSS) / `CSS_FEATURE_FLAG_PREFIX` (TS)	string	`'cxFeat_'`	core-libs/styles/scss/_features.scss:L6-L6; core-libs/core/src/features-config/services/feature-styles.service.ts:L31-L36	`getFeatureCssClass` (core-libs/styles/scss/_features.scss:L12-L14); `getCssClass` (core-libs/core/src/features-config/services/feature-styles.service.ts:L158-L162)
`forFeature(..., $classTarget)`	`'ancestorSelector' | 'currentSelector'`	`'ancestorSelector'`	core-libs/styles/scss/_features.scss:L41-L41	core-libs/styles/scss/_features.scss:L51-L61

7. Commenti e note notevoli dal sorgente

- "Let's NOT add here any wildcard property ... We want this interface to be STRICT" (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L7-L10): la rottura in compilazione quando un toggle sparisce è una **scelta**, non un effetto collaterale.
- "don't export from './config/feature-toggles' as it contains private API" (core-libs/core/src/features-config/feature-toggles/index.ts:L7-L7).
- "for backward compatibility with the deprecated FeaturesConfig" (core-libs/core/src/features-config/features-config.module.ts:L35-L35).
- JSDoc di `provideFeatureToggles`: "For using in a library, call `provideDefaultFeatureToggles() instead."` (nel sorgente il backtick non è chiuso: core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L21-L21`).
- I `@deprecated` di `FeaturesConfig` coprono la classe, `features`, `level`, la index signature e `disableConfigUpdates` (core-libs/core/src/features-config/config/features-config.ts:L11-L11, core-libs/core/src/features-config/config/features-config.ts:L33-L33, core-libs/core/src/features-config/config/features-config.ts:L54-L54, core-libs/core/src/features-config/config/features-config.ts:L73-L73, core-libs/core/src/features-config/config/features-config.ts:L102-L102). L'ultimo rimanda a CXSPA-13592 per lo spostamento in un injection token.
- "The properties below should be moved in the future to the global config, because they are not temporary feature toggles but rather permanent config options" (core-libs/core/src/features-config/config/features-config.ts:L90-L99): una distinzione esplicita tra *toggle temporaneo* e *opzione permanente*.
- `@deprecated Unused directive. Please use named feature flags instead of feature level.` (core-libs/core/src/features-config/directives/feature-level.directive.ts:L11-L11).
- "🚨 CAUTION. The approach of using `forVersion($level)` in this file is deprecated" (core-libs/styles/scss/_versioning.scss:L1-L2) e `// @deprecated since 2211.20` (core-libs/styles/scss/_versioning.

scss:L63-L63): una deprecazione dentro SCSS, dove non c'è nessun compilatore che la segnali.

- "IMPORTANT: Please mind to call `useFeatureStyles(feature)` ... Otherwise the feature-flagged styles MIGHT NOT be activated" (core-libs/styles/scss/_features.scss:L18-L21).
- `$featureMessagingItems: true;` (core-libs/styles/scss/_features.scss:L1-L1): variabile che non è referenziata da nessun'altra parte del repo (F80).
- Lo spec avverte che la precedenza tra `FeaturesConfig` e `FeatureToggles` "might not be intuitive" (core-libs/core/src/features-config/features-config.module.spec.ts:L84-L93).
- Il commento della config vitest di checkout spiega perché serve l'alias di `@spartacus/core` verso il sorgente: altrimenti "`*cxFeature` never sees the mocked toggles" (feature-libs/checkout/vitest.config.ts:L35-L42).
- JSDoc incoerente: `a11yCardNotificationMessage` descrive un fix sulla tabella organization, non solo sul messaggio della card (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L237-L242).

8. Extension point

PUNTO	TIPO	DEFINIZIONE	NOTE
`provideFeatureToggles`, `provideFeatureTogglesFactory`	funzioni provider (app)	core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L25-L52	da usare nel root injector
`provideDefaultFeatureToggles`, `provideDefaultFeatureTogglesFactory`	funzioni provider (librerie)	core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L54-L86	regola ESLint nelle librerie Spartacus
`FeatureToggles`	classe astratta DI + interfaccia	core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L15-L25	iniettare `private`
`FeatureTogglesChunk`, `DefaultFeatureTogglesChunk`, `RootFeatureToggles`, `DefaultFeatureToggles`	`InjectionToken`	core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L33-L78	"Should not be used directly" per i chunk
`FeatureToggleKey`, `FeatureToggleExpression`, `FeatureTogglesFactory`	tipi	core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L27-L28, core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L14-L14	—
`FeatureDirective` (`*cxFeature`)	direttiva standalone	core-libs/core/src/features-config/directives/feature.directive.ts:L11-L29	importabile anche via `FeaturesConfigModule`

PUNTO	TIPO	DEFINIZIONE	NOTE
`FeatureStylesService`	servizio con metodi `protected` sovrascrivibili (`isEnabled`, `addClass`, `removeClass`, `getCssClass`)	`core-libs/core/src/features-config/services/feature-styles.service.ts:L25-L163`	sostituibile via DI
`useFeatureStyles`	funzione da injection context	`core-libs/core/src/features-config/utils/use-feature-styles.ts:L32-L40`	nel costruttore
`forFeature($feature, $classTarget)`	mixin SCSS	`core-libs/styles/scss/_features.scss:L41-L62`	da accoppiare a `useFeatureStyles`
`isFeatureEnabled`	funzione pura	`core-libs/core/src/features-config/utils/feature-config-utils.ts:L48-L65`	legge un `Config`
`FeaturesConfig`, `FeatureConfigService`, `FeatureLevelDirective`, `isFeatureLevel`, `forVersion`	legacy	vedi §3.4–3.9	`@deprecated`: non costruirci sopra codice nuovo
`provideMockFeatureToggles`, `MockFeatureTogglesController`	test util	`core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L48-L218`	**non** nel public API; solo con alias
`FeatureTogglesInterface`, `defaultFeatureToggles`	—	`core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L11-L11`, `core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1013-L1013`	**non** esportati (`core-libs/core/src/features-config/feature-toggles/index.ts:L7-L9`)

Tutto ciò che è pubblico arriva da `core-libs/core/public_api.ts:L19-L19` → `core-libs/core/src/features-config/index.ts:L7-L15`.

Ricette pertinenti della Parte III:

- 50 — Ricette: configurazione, DI, interceptor, eventi: fornire i toggle (`provideFeatureToggles` / `provideFeatureTogglesFactory`) accanto agli altri override di configurazione; scegliere tra livello root e default.
- 53 — Ricette: feature lib lazy, carrello/checkout, stili, traduzioni: stili condizionati da toggle (`forFeature` + `useFeatureStyles`) negli override SCSS; toggle di default in una feature lib custom con `provideDefaultFeatureToggles`.
- 54 — API pubblica vs interna, upgrade, anti-pattern, checklist: cosa succede quando un toggle viene rimosso, come usare A09 e A10 per pianificare un upgrade, perché non estendere classi referenziando `featureToggles`.

Schema minimo (usa solo simboli esportati da `@spartacus/core`):

```ts
// Applicazione (root injector, modulo eager)
providers: [
  provideFeatureToggles({ a11yKeyboardAccessibleZoom: true }),
];

// Libreria propria: default sovrascrivibili dall'app
providers: [provideDefaultFeatureToggles({ a11yKeyboardAccessibleZoom: false })];

// Componente
export class MyComponent {
  private featureToggles = inject(FeatureToggles); // private: regola ESLint
  constructor() {
    useFeatureStyles('a11yKeyboardAccessibleZoom'); // se lo SCSS usa forFeature(...)
  }
}
```

Nota: una libreria esterna non può aggiungere **nuove chiavi** a `FeatureToggles` senza una module augmentation dell'interfaccia, che però non è esportata (core-libs/core/src/features-config/feature-toggles/index.ts:L7-L9). DA VERIFICARE: nel repo non c'è un pattern documentato per estendere `FeatureTogglesInterface` da librerie di terze parti.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. **Ponte a senso unico.** `provideConfig({ features: { x: true } })` non arriva a `inject(FeatureToggles).x`: il ponte copia solo toggle → config (core-libs/core/src/features-config/feature-toggles/populate-feature-toggles-to-features-config.ts:L18-L33). In un'app che usa ancora la config legacy, `*cxFeature="'x'"` e `this.featureToggles.x` possono quindi dare risultati diversi **sulla stessa chiave**. Lo stesso vale per gli stili: `FeatureStylesService` legge `FeatureToggles` (core-libs/core/src/features-config/services/feature-styles.service.ts:L27-L29), quindi la classe `cxFeat_x` non compare.
2. **Allo stesso livello la config legacy vince.** Con `provideConfig({features:{x:true}})` e `provideFeatureToggles({x:false})` nello stesso livello, `isEnabled('x')` restituisce `true` qualunque sia l'ordine dei provider, perché il chunk del ponte entra presto nell'albero DI tramite `forRoot()` (core-libs/core/src/features-config/features-config.module.spec.ts:L84-L111). Tra livelli diversi vale invece ROOT > DEFAULT (core-libs/core/src/features-config/features-config.module.spec.ts:L37-L44).
3. **Due merge diversi.** I toggle si uniscono con `Object.assign` (shallow, vince l'ultimo); la config con `deepMerge` (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L18-L22 contro core-libs/core/src/config/config-tokens.ts:L10-L12). Per valori booleani la differenza non si vede, ma l'ordine di precedenza segue regole diverse (punto 2).
4. **Moduli lazy.** I token sono `providedIn: 'root'` e i provider "should be provided in the root injector" (core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L16-L19, core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L54-L57): un `provideFeatureToggles` dentro un modulo lazy non arriva né a `FeatureToggles` né a `Config.features`. `ConfigurationService` raccoglie dagli injector lazy solo `ConfigChunk` e `DefaultConfigChunk` (core-libs/core/src/config/services/configuration.service.ts:L58-L65), e il ponte che converte i toggle in `ConfigChunk` è registrato soltanto nel root da `forRoot()` (core-libs/core/src/features-config/features-config.module.ts:L33-L35, core-libs/core/src/features-config/feature-toggles/populate-feature-

toggles-to-features-config.ts:L21-L33). Solo un `provideConfig({ features: ... })` legacy in un modulo lazy viene unito in `Config` da `ConfigurationService`, se `disableConfigUpdates` è falso (core-libs/core/src/config/services/configuration.service.ts:L92-L106).

5. `*cxFeature` **non è reattiva.** Rivaluta solo quando cambia l'input; se cambia un toggle con la stessa stringa d'input, la vista non viene ri-renderizzata (core-libs/core/src/features-config/directives/feature.directive.ts:L19-L29).
6. **Stringhe interpretate come livelli.** `features: { x: '2.1' }` non è "truthy": viene letto come livello, quindi `isFeatureLevel(config, '2.1')`, che con il livello di default `'3.0'` restituisce `true` (core-libs/core/src/features-config/utils/feature-config-utils.ts:L57-L60, core-libs/core/src/features-config/features-config.module.ts:L28-L40). Con `forRoot('')` il livello diventa `'*'`, cioè tutti i livelli (core-libs/core/src/features-config/features-config.module.ts:L38-L38).
7. **Stili che non si accendono.** Se un componente non chiama `useFeatureStyles` nel costruttore, i blocchi `forFeature` restano spenti anche con il toggle a `true` (core-libs/core/src/features-config/utils/use-feature-styles.ts:L11-L31). La chiamata fuori da un injection context lancia `MISSING_INJECTION_CONTEXT` (angular:packages/core/src/di/contextual.ts:L77-L88). Un indizio utile: se la classe compare solo quando è montato *un altro* componente che registra lo stesso flag, significa che manca la registrazione nel componente stilizzato.
8. **Contatori anche per flag spenti.** `registerUsage` incrementa sempre; `unregisterUsage` con contatore 0 avvisa solo in dev mode (core-libs/core/src/features-config/services/feature-styles.service.ts:L89-L115).
9. **Nessuna reazione alle mutazioni.** Se un toggle passa da `true` a `false` dopo `addClass`, `unregisterUsage` salta `removeClass` perché `isEnabled(feature)` è falso (core-libs/core/src/features-config/services/feature-styles.service.ts:L111-L113), e in ogni caso `getCssClass` restituirebbe `undefined`: la classe **non** viene rimossa (core-libs/core/src/features-config/services/feature-styles.service.ts:L144-L150, core-libs/core/src/features-config/services/feature-styles.service.ts:L158-L162). In produzione `FeatureToggles` è un oggetto costruito una sola volta, quindi il caso riguarda soprattutto i test.
10. **Il "root" non è** `<html>`. Le classi finiscono su `compRef.location.nativeElement`, cioè l'elemento del componente di bootstrap (core-libs/core/src/features-config/services/feature-styles.service.ts:L65-L66). Per gli stili su `:root` servono `currentSelector` (core-libs/styles/scss/root.scss:L36-L44) e l'aggiunta manuale su `document.documentElement` in `StorefrontComponent` (core-libs/storefront/layout/main/storefront.component.ts:L141-L147).
11. **App nuova contro app migrata.** `ng add` accende tutti i 107 toggle (core-libs/schematics/src/add-spartacus/spartacus-feature-toggles.ts:L84-L86), mentre i default della libreria ne hanno 75 a `false` (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1013-L1121). Due progetti con la stessa versione di Spartacus possono quindi avere DOM e stili diversi.
12. **Rimozione di un toggle = errore di compilazione.** Chi referenzia una chiave rimossa non compila più: è voluto (core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L7-L10). È anche il motivo per cui `FeatureToggles` va iniettato `private` (tools/eslint-rules/rules/feature-toggles-must-be-private.ts:L11-L21). Se una sottoclasse cliente legge `this.featureToggles.x` da un campo `protected`, la rimozione di `x` rompe il suo codice.
13. `provideAuthorizationCodeFlowByDefault` **e** `inject()`**.** La funzione chiama `inject()` nel proprio corpo, quindi va invocata in un injection context; inoltre `authorizationCodeFlowByDefault ?? enable` ignora `enable` ogni volta che il toggle è definito, e il default lo definisce sempre (core-libs/core/src/auth/user-auth/config/default-auth-config.ts:L37-L46).
14. **Mock nei test.** `MockFeatureDirective` di storefront ignora i valori e mostra sempre il ramo non negato (core-libs/storefront/shared/test/mock-feature-directive.ts:L16-L22). `provideMockFeatureToggles` funziona con `*cxFeature` solo se il token `FeatureConfigService` ha la stessa identità di classe; da qui l'a-

lias di `@spartacus/core` verso il sorgente in checkout (feature-libs/checkout/vitest.config.ts:L35-L42).

15. **Non esiste una pipe** per i toggle (nessuna delle pipe del repo, es. `cxTranslate` in core-libs/core/src/i18n/translate.pipe.ts:L25-L28 o `cxArgs` in feature-libs/asm/core/utils/args/args.pipe.ts:L33-L33, legge `FeatureToggles`). Nei template si usa `*cxFeature`; per valori calcolati si espone un campo dal componente letto da `FeatureToggles`.

---

10. Come fare debug

- **Valore effettivo di un toggle.** In un componente o in un test: `inject(FeatureToggles)` restituisce l'oggetto finale già unito (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L15-L24). Per capire *da dove* arriva un valore, confronta `inject(DefaultFeatureToggles)` e `inject(RootFeatureToggles)`: sono token pubblici (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L33-L58).
- **Divergenza tra template e TS.** Se `*cxFeature` e `this.featureToggles.x` non concordano, cerca `provideConfig(` con `features` nell'app (trappole 1 e 2). Il valore che vede la direttiva è `inject(Config).features.x`, letto da `isFeatureEnabled` (core-libs/core/src/features-config/utils/feature-config-utils.ts:L48-L65).
- **Classe CSS assente.** Ispeziona l'elemento root dell'app (non `<html>`) e cerca `cxFeat_<chiave>`. Se manca: (a) il toggle è falsy in `FeatureToggles` (core-libs/core/src/features-config/services/feature-styles.service.ts:L120-L122); (b) nessun componente montato ha chiamato `useFeatureStyles('<chiave>')` (il dossier conta 56 chiamate: `git grep -n "useFeatureStyles('<chiave>')"`); (c) il componente è stato distrutto e il contatore è tornato a 0 (core-libs/core/src/features-config/services/feature-styles.service.ts:L103-L115). In dev mode, il warning `Feature flag CSS: "<chiave>" is already not used` indica una de-registrazione senza registrazione corrispondente (core-libs/core/src/features-config/services/feature-styles.service.ts:L103-L108).
- **Regola SCSS che non si applica pur con la classe presente.** Controlla il CSS compilato: con `ancestorSelector` la regola è `.cxFeat_x <selettore>` e richiede che l'elemento stilizzato stia *dentro* l'elemento root; per stili sull'elemento root stesso serve `currentSelector` (core-libs/styles/scss/_features.scss:L51-L61). Un errore di compilazione `forFeature: $classTarget must be either ...` indica un secondo argomento sbagliato (core-libs/styles/scss/_features.scss:L46-L48).
- **Catalogo e uso di una chiave.** A09 riporta per ogni chiave le righe di interfaccia e default e i conteggi d'uso in TS/HTML/SCSS. Per i dettagli, `git grep -n "'<chiave>'"` trova sia `*cxFeature` sia `useFeatureStyles`/`forFeature`.
- **Deprecazioni nel proprio codice.** A10 elenca i 165 `@deprecated` con simbolo e riferimento. Per le migrazioni automatiche tra versioni, vedi 43 — Schematics e migrazioni.
- **Nei test.** Usa `provideMockFeatureToggles({...})` e poi `TestBed.inject(MockFeatureTogglesController).set(key, value)` seguito da `fixture.detectChanges()`, come nell'esempio JSDoc (core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L39-L58). Se `*cxFeature` non reagisce, verifica che `FeatureConfigService` sia la stessa classe di quella sostituita dal mock (trappola 14).

11. Domande di autoverifica

1. **Perché** `FeatureTogglesInterface` **non ha una index signature?** Perché una chiave rimossa deve causare un errore di compilazione nel codice cliente, così chi la usa sa di dover adattare il codice. — `core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L7-L11`
2. **Un'app fornisce** `provideConfig({ features: { x: true } })`**. Che valore restituisce** `inject(FeatureToggles).x`**?** Il default di libreria (o `undefined`), non `true`: il ponte copia solo `FeatureToggles` → `Config.features`, mai il contrario. — `core-libs/core/src/features-config/feature-toggles/populate-feature-toggles-to-features-config.ts:L18-L33`
3. **Con** `provideConfig({features:{x:true}})` **e** `provideFeatureToggles({x:false})` **nell'app, cosa restituisce** `FeatureConfigService.isEnabled('x')`**? E se si invertono i provider?** `true` in entrambi i casi: allo stesso livello `FeaturesConfig` vince indipendentemente dall'ordine. — `core-libs/core/src/features-config/features-config.module.spec.ts:L84-L102`
4. **Perché** `defaultAuthConfigFactory` **usa** `inject(FeatureToggles)` **e non** `FeatureConfigService`**?** Perché la factory contribuisce a `DefaultConfig`/`Config`, da cui dipende `FeatureConfigService`: si creerebbe un ciclo di DI. `FeatureToggles` non dipende da `Config`. — `core-libs/core/src/auth/user-auth/config/default-auth-config.ts:L76-L83`, `tools/eslint-rules/rules/feature-toggles-must-be-private.ts:L23-L26`
5. **Un componente ha** `@include forFeature('x')` **nel suo SCSS, il toggle** `x` **è** `true`**, ma lo stile non si applica. Causa più probabile?** Il componente non chiama `useFeatureStyles('x')` nel costruttore, quindi `FeatureStylesService` non aggiunge `cxFeat_x` all'elemento root. — `core-libs/core/src/features-config/utils/use-feature-styles.ts:L11-L40`, `core-libs/core/src/features-config/services/feature-styles.service.ts:L89-L95`
6. **Perché** `FeatureStylesService.init` **scorre** `usagesCounter` **invece di limitarsi a salvare l'elemento root?** Perché i costruttori dei componenti (a partire dal root component) chiamano `registerUsage` prima che Angular invochi gli `APP_BOOTSTRAP_LISTENER`; in quel momento `addClass` non fa nulla perché `rootElement` non è ancora impostato. — `core-libs/core/src/features-config/services/feature-styles.service.ts:L65-L77`, `angular:packages/core/src/application/application_ref.ts:L775-L794`
7. **Quando si usa** `forFeature(..., 'currentSelector')`**?** Solo per gli stili dell'elemento root stesso; l'unico uso di produzione è in `root.scss` per `a11yPreventWindowsHighContrastOverride`. — `core-libs/styles/scss/_features.scss:L38-L40`, `core-libs/styles/scss/root.scss:L36-L44`
8. **Cosa restituisce** `isFeatureEnabled(config, 'x')` **se** `config.features.x === '2.1'` **e** `features.level` **vale** `'3.0'`**?** `true`: la stringa è interpretata come livello e `isInLevel('3.0', '2.1')` confronta 3 > 2. — `core-libs/core/src/features-config/utils/feature-config-utils.ts:L15-L34`, `core-libs/core/src/features-config/utils/feature-config-utils.ts:L57-L60`
9. **Perché** `FeatureToggles` **deve essere iniettato** `private`**?** Perché la rimozione di un toggle (il suo normale fine vita) diventerebbe un breaking change TypeScript per i clienti che lo referenziano da una sotto-classe. — `tools/eslint-rules/rules/feature-toggles-must-be-private.ts:L11-L21`
10. **Un'app creata con** `ng add` **e una con i soli default di libreria partono con gli stessi toggle?** No: lo schematic imposta tutte le chiavi a `true`, mentre i default ne hanno 75 su 107 a `false`. — `core-libs/schematics/src/add-spartacus/spartacus-feature-toggles.ts:L80-L93`, `core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1013-L1121`

1. A cosa serve e perché esiste

Spartacus non è un'applicazione da clonare: è un insieme di librerie npm che vanno *innestate* in un'applicazione Angular generata con `ng new`. L'innesto richiede decine di modifiche coordinate (moduli `app/spartacus/*`, config OCC, i18n, stili SCSS, `angular.json`, `package.json`, eventualmente SSR) e, a ogni release, modifiche inverse per adattare il codice del cliente ai breaking change. Il pacchetto `@spartacus/schematics` automatizza entrambe le cose con il meccanismo standard degli Angular schematics (vedi 08 — Schematics e builder per la parte Angular):

- **installazione** (`ng add @spartacus/schematics`, poi `ng add @spartacus/<feature-lib>`): scaffolding dell'app, configurazione, feature lazy-loaded, SSR;
- **generatori** di supporto (`add-cms-component`, `wrapper-module`, `ai-context`);
- **migrazioni** eseguite da `ng update` (`migrations.json`) e **modernizzazioni** manuali (`modernize-app-*`) per gli upgrade più invasivi.

Il pacchetto si dichiara con versione `221121.22.0` e registra la collection in `./src/collection.json` e le migrazioni in `./src/migrations/migrations.json` (core-libs/schematics/package.json:L2-L3, core-libs/schematics/package.json:L90-L90, core-libs/schematics/package.json:L43-L89). Nota: la versione dello schematics (`221121.22.0`) non coincide con la `2612.0.0` della root del monorepo; la cosa conta perché da quella versione dipendono `~<versione>` delle dipendenze installate e il "feature level" generato (core-libs/schematics/src/shared/utils/package-utils.ts:L139-L149).

Il pacchetto esporta anche utility per gli schematics delle altre librerie, con un avvertimento esplicito: "it exports utils for other Spartacus libs' schematics, but is not intended as a public API for external use. It may change without deprecation." (core-libs/schematics/index.ts:L7-L13). Ogni feature lib (es. `@spartacus/checkout`) ha infatti una propria piccola collection che riusa queste utility (feature-libs/checkout/schematics/add-checkout/index.ts:L13-L43).

Infine, un pezzo recente: il pacchetto `@spartacus/skills` e lo schematic `ai-context`, che copiano nel progetto del cliente una "skill" per assistenti AI (`.claude/skills/...`, `.agents/skills/...`), più una *living migration* che la tiene aggiornata a ogni `ng update` (core-libs/schematics/src/ai-context/index.ts:L16-L22, core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L22-L31).

> Nota: la semantica del devkit e della CLI citata nel capitolo (`chain`, task, `--dry-run`, selezione delle migrazioni di `ng update`, `ng-add.save`) è verificata sui sorgenti pubblicati di `@angular-devkit/schematics` e `@angular/cli` 21.2.23 (prefisso `deps:devkit/…`); vedi §3.9, §6 e le trappole 8, 16, 18 e 19 di §9.

Capitoli collegati: i feature toggle generati da `ng add` in 42 — Feature toggle e deprecazioni; lazy loading e `featureModules` in 12 — Feature module e lazy loading; `provideConfig` in 11 — Configurazione; lo stack SSR che `add-ssr` imposta in 39 — SSR ottimizzato; stili in 38 — Stili e theming; test tooling in 44 — Test tooling; strategia di upgrade in 54 — Upgrade safe.

2. Mappa dei file

PATH	RUOLO
`core-libs/schematics/package.json`	versione `221121.22.0`, `ng-add.save: devDependencies`, `ng-update.migrations`, `packageGroup` di tutte le `@spartacus/*`, script `build/clean/copy-feature-toggles/test`
`core-libs/schematics/index.ts`	"public API" (non stabile): `SpartacusOptions` + `src/shared/index`
`core-libs/schematics/copy-feature-toggles.js`	pre-build: copia `feature-toggles.ts` da core in `src/feature-toggles.copied-from-core-lib.ts` (git-ignored)
`core-libs/schematics/jest.schematics.config.js`, `core-libs/schematics/setup-jest.ts`, `core-libs/schematics/project.json`	test Jest (`*_spec.ts`), target Nx `test-jest`
`core-libs/schematics/src/collection.json`	9 schematics: `ng-add`, `add-spartacus`, `add-ssr`, `add-cms-component`, `wrapper-module`, `ai-context`, 3 × `modernize-app-*`
`core-libs/schematics/src/dependencies.json`	generato da `tools/schematics/dependency-collector.ts`: peer deps di ogni lib + deps della root
`core-libs/schematics/src/ng-add/index.ts`	`ng-add` = `add-spartacus` (+ `add-ssr` se `ssr`)
`core-libs/schematics/src/add-spartacus/index.ts`	`addSpartacus`: chain di ~20 rule; stili, budget, index.html, preprocessor, deps
`core-libs/schematics/src/add-spartacus/schema.json`, `core-libs/schematics/src/add-spartacus/schema.ts`	opzioni condivise da `ng-add`/`add-spartacus`/`add-ssr`
`core-libs/schematics/src/add-spartacus/{create-app-module,update-app-config,add-storefront-component-to-app-component,store,spartacus,spartacus-features,configuration,spartacus-feature-toggles,update-app-module}.ts`	singole rule di installazione

tools/breaking-changes/*.ts	generatori dei dati di deprecazione
feature-libs/checkout/schematics/*	esempio di collection di feature lib
core-libs/skills/*	pacchetto @spartacus/skills (skill spartacus-developer)

3. Come funziona passo per passo

3.1 Pacchetto, build e collection

1. **Build senza ng-packagr.** npm run build rigenera dependencies.json (generate:deps) e compila con tsc -p ./tsconfig.schematics.json; clean esegue copy-feature-toggles (core-libs/schematics/package.json:L14-L16). generate:deps è ts-node ./tools/schematics/dependency-collector.ts (package.json:L62-L64).
2. dependencies.json. Il collector scrive core-libs/schematics/src/dependencies.json: per ogni lib sotto projects, core-libs, feature-libs, integration-libs raccoglie le peerDependencies, per il package.json root (name storefrontapp) le dependencies (tools/schematics/dependency-collector.ts:L21-L31, tools/schematics/dependency-collector.ts:L46-L76). Questo file è la "fonte di verità" delle versioni installate da ng add e da ng update.
3. **Feature toggle copiati.** copy-feature-toggles.js copia core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts in src/feature-toggles.copied-from-core-lib.ts (core-libs/

schematics/copy-feature-toggles.js:L5-L10), file ignorato da git (core-libs/schematics/.gitignore:L21-L22). Serve a addFeatureToggles senza dipendere a runtime da @spartacus/core (§3.3).

4. **Collection.** collection.json registra 9 schematics; ng-add è private/hidden con alias install, gli altri hanno alias brevi (spa, ssr, cms, wrapper, ai) (core-libs/schematics/src/collection.json:L3-L53). ng-add, add-spartacus e add-ssr condividono lo stesso ./add-spartacus/schema.json (core-libs/schematics/src/collection.json:L7-L7, core-libs/schematics/src/collection.json:L15-L15, core-libs/schematics/src/collection.json:L21-L21); wrapper-module non dichiara uno schema (core-libs/schematics/src/collection.json:L30-L34).
5. ng-add è un semplice chain di schematic('add-spartacus') e, se options.ssr, schematic('add-ssr') (core-libs/schematics/src/ng-add/index.ts:L17-L24).

3.2 Opzioni (Schema / LibraryOptions)

- LibraryOptions è la base comune: project, lazy, features, debug, internal.existingSpartacusApplication, options (core-libs/schematics/src/shared/utils/lib-utils.ts:L85-L110).
- Schema di add-spartacus aggiunge baseUrl, occPrefix, baseSite, currency, language, urlParameters, useMetaTags, featureLevel (@deprecated), overwriteAppComponent, ssr, theme, aiTools; AiTool = 'claude' | 'agents' (core-libs/schematics/src/add-spartacus/schema.ts:L9-L27).
- Lo schema JSON propone 16 feature di default con x-prompt a lista (core-libs/schematics/src/add-spartacus/schema.json:L14-L34, core-libs/schematics/src/add-spartacus/schema.json:L94-L96) e default lazy: true, baseUrl: "https://localhost:9002", overwriteAppComponent: true, ssr: false, debug: false, aiTools: ["agents"] (core-libs/schematics/src/add-spartacus/schema.json:L333-L346, core-libs/schematics/src/add-spartacus/schema.json:L376-L385, core-libs/schematics/src/add-spartacus/schema.json:L390-L397).

3.3 add-spartacus: la catena di installazione

addSpartacus calcola **prima** le feature con le dipendenze transitive (analyzeCrossFeatureDependencies) e l'elenco delle dipendenze npm (prepareDependencies), poi restituisce un chain (core-libs/schematics/src/add-spartacus/index.ts:L531-L590). Le rule, nell'ordine:

1. detectAndSetupAppStructure — pretende un'app standalone con app.config.ts e il naming "2016" (app.component.ts); altrimenti SchematicsException con il consiglio di ricreare l'app con --file-name-style-guide=2016 e senza --standalone=false (core-libs/schematics/src/add-spartacus/index.ts:L324-L369).
2. createAppModule — crea un app.module.ts vuoto (@NgModule({})) accanto ad app.component.ts (core-libs/schematics/src/add-spartacus/create-app-module.ts:L22-L81). Spartacus continua quindi a configurarsi in un NgModule, agganciato all'app standalone tramite:
3. updateAppConfig — aggiunge provideHttpClient(withFetch(), withInterceptorsFromDi()) e importProvidersFrom(AppModule) ai providers di appConfig, evitando duplicati per confronto testuale (core-libs/schematics/src/add-spartacus/update-app-config.ts:L19-L46, core-libs/schematics/src/add-spartacus/update-app-config.ts:L55-L110).
4. addStorefrontComponentToAppComponent — importa StorefrontComponent e **sostituisce** l'array imports del @Component (removeOldImports: true) (core-libs/schematics/src/add-spartacus/add-storefront-component-to-app-component.ts:L36-L48, core-libs/schematics/src/add-spartacus/add-imports-to-component-decorator.ts:L56-L89).
5. analyzeApplication — imposta options.internal.existingSpartacusApplication se esiste già SpartacusFeaturesModule e, per app esistenti, verifica che i "marker module" degli importAfter siano installati (core-libs/schematics/src/shared/utils/feature-utils.ts:L279-L370).

6. setupStoreModules — `StoreModule.forRoot({})` ed `EffectsModule.forRoot([])` in `app.module.ts` (core-libs/schematics/src/add-spartacus/store.ts:L48-L70).
7. scaffoldStructure — via `ensureModuleExists` crea `app/spartacus/spartacus.module.ts` (dichiarato in `app`), `spartacus-features.module.ts` e `spartacus-configuration.module.ts` (dichiarati in `spartacus`) (core-libs/schematics/src/shared/utils/workspace-utils.ts:L170-L198).
8. setupSpartacusModule — `BaseStorefrontModule` in `imports` (order 0) e `exports` di `SpartacusModule` (core-libs/schematics/src/add-spartacus/spartacus.ts:L53-L84).
9. setupSpartacusFeaturesModule — moduli core/storefront fissi: `AuthModule.forRoot()`, `LogoutModule`, `LoginRouteModule`, moduli CMS base, consensi, Product, `CostCenterOccModule`, event module, `ExternalRoutesModule.forRoot()` (core-libs/schematics/src/add-spartacus/spartacus-features.ts:L51-L276).
10. addSpartacusConfiguration — in `spartacus-configuration.module.ts`: `provideConfigFactory(layoutConfigFactory)`, `provideConfig(mediaConfig)`, `...defaultCmsContentProviders`, poi config OCC, site context, i18n e `features.level` (core-libs/schematics/src/add-spartacus/configuration.ts:L83-L122, core-libs/schematics/src/add-spartacus/configuration.ts:L157-L208). Dettagli: con `useMetaTags` il `baseUrl` è omesso e `prefix` compare solo se `occPrefix` è valorizzato (core-libs/schematics/src/add-spartacus/configuration.ts:L210-L221); le CSV di site context passano per `parseCSV` (valute maiuscole, lingue minuscole) (core-libs/schematics/src/add-spartacus/configuration.ts:L124-L151, core-libs/schematics/src/shared/utils/transform-utils.ts:L7-L19); i18n usa `translationsEn`, `translationChunksConfig`, `fallbackLang: 'en'` (core-libs/schematics/src/add-spartacus/configuration.ts:L183-L196, core-libs/schematics/src/add-spartacus/configuration.ts:L223-L231); `features.level` è `featureLevel` o il `major.minor` dello schematics, funzione marcata `@deprecated` (core-libs/schematics/src/add-spartacus/configuration.ts:L233-L242, core-libs/schematics/src/shared/utils/package-utils.ts:L147-L149).
11. addFeatureToggles — `provideFeatureToggles({...})` con **tutte** le chiavi di `defaultFeatureToggles` a `true`, lette con `require` dal file copiato (core-libs/schematics/src/add-spartacus/spartacus-feature-toggles.ts:L62-L113, core-libs/schematics/src/shared/constants.ts:L1176-L1177).
12. updateAppModule — rimuove l'`AppRoutingModule` locale (import e file `app-routing.module.ts`) e importa quello di `@spartacus/storefront` con order 2 (core-libs/schematics/src/add-spartacus/update-app-module.ts:L80-L145).
13. **Stili** — `createStylesConfig` crea `styles-config.scss` con `$styleVersion` (core-libs/schematics/src/add-spartacus/index.ts:L70-L86, core-libs/schematics/src/shared/utils/styling-utils.ts:L10-L13); `installStyles` prende il primo elemento di `build.options.styles` e, se è un `.scss`, vi appende gli import di styles-config, `@spartacus/styles/scss/core`, Bootstrap vendorizzato sotto `@spartacus/styles/vendor/bootstrap/scss/*`, `@spartacus/styles/index` e, opzionalmente, il tema; se non è un `.scss` si limita a un warning (core-libs/schematics/src/add-spartacus/index.ts:L89-L89, core-libs/schematics/src/add-spartacus/index.ts:L120-L128, core-libs/schematics/src/add-spartacus/index.ts:L102-L187).
14. updateMainComponent — `<cx-storefront/>` in `app.component.html`, sostituendo tutto se `overwriteAppComponent` (core-libs/schematics/src/add-spartacus/index.ts:L189-L229). Con `useMetaTags`, `updateIndexFile` aggiunge le meta `occ-backend-base-url`/`media-backend-base-url` (core-libs/schematics/src/add-spartacus/index.ts:L231-L254).
15. increaseBudgets — `maximumError: '3.5mb'` per il budget `initial` in production (core-libs/schematics/src/add-spartacus/index.ts:L256-L315).
16. createStylePreprocessorOptions — `node_modules/` negli `includePaths` di build e test, `sass.silenceDeprecations` solo in build (core-libs/schematics/src/add-spartacus/index.ts:L371-L464), con `'import'` silenziato e la motivazione CXSPA-447 (core-libs/schematics/src/shared/utils/workspace-utils.ts:L209-L243).
17. addFeatures — per ogni feature `addLibraryFeature` + eventuali `wrapper-module` (§3.4).

18. `addAiContext` — `@spartacus/skills` in devDependencies (`overwrite: false`) se `aiTools` non è vuoto (core-libs/schematics/src/add-spartacus/ai-context.ts:L27-L48).
19. **Dipendenze** — sotto-chain: `addPackageJsonDependencies(prepareDependencies(features))`, forzatura di `rxjs` alla versione Spartacus, `installPackageJsonDependencies()`, `replaceCaretWithTildeForSpartacusDependencies` (core-libs/schematics/src/add-spartacus/index.ts:L571-L585). `prepareDependencies` unisce le core deps (`core`, `storefront`, `assets`, `styles`), le librerie delle feature (con `~<versione schematics>`) e le terze parti (core-libs/schematics/src/add-spartacus/index.ts:L466-L480, core-libs/schematics/src/shared/utils/package-utils.ts:L256-L294). Il passaggio ^→~ è motivato dalla scelta, dalla 2211.19, di rilasciare breaking change nei "minor" (core-libs/schematics/src/add-spartacus/index.ts:L482-L529).
20. `scheduleAiContext` — accoda `NodePackageInstallTask` e, dipendente da esso, `RunSchematicTask('ai-context', …)` (core-libs/schematics/src/add-spartacus/ai-context.ts:L54-L76).
21. `finalizeInstallation` — per un'app già Spartacus, warning "🚨 Detected Spartacus installation..." con l'elenco delle feature da verificare e ordinare (core-libs/schematics/src/shared/utils/lib-utils.ts:L897-L909).

3.4 Feature: `SchematicConfig`, `addFeatures`, `addLibraryFeature`

Ogni feature installabile è descritta da un oggetto dichiarativo `SchematicConfig`: `library {featureName, mainScope, featureScope?, b2b?}`, `folderName`, `moduleName`, `featureModule` (singolo o array), `rootModule?`, `lazyLoadingChunk?`, `i18n?`, `styles?`, `assets?`, `customConfig?`, `dependencyFeatures?`, `importAfter?` (core-libs/schematics/src/shared/utils/lib-utils.ts:L115-L199). Tutte le config sono elencate in `SCHEMATICS_CONFIGS`, che "*Must* be updated when adding a new schematics library or a feature" (core-libs/schematics/src/shared/schematics-config-mappings.ts:L99-L198); `generateMappings()` ne ricava 4 mappe (`libraryFeatureMapping`, `featureFeatureModuleMapping`, `featureRootModuleMapping`, `featureSchematicConfigMapping`) (core-libs/schematics/src/shared/schematics-config-mappings.ts:L203-L286).

1. **Closure delle dipendenze.** `analyzeCrossFeatureDependencies` raccoglie ricorsivamente le `dependencyFeatures` (es. Digital Payments trascina User-Account, User-Profile, Cart, Order, Checkout) e le ordina (core-libs/schematics/src/shared/utils/dependency-utils.ts:L29-L60).
2. **Ordine globale.** All'import di `graph-utils.ts` vengono calcolati, come costanti di modulo, `crossLibraryInstallationOrder` e `crossFeatureInstallationOrder` (core-libs/schematics/src/shared/utils/graph-utils.ts:L41-L49) con l'algoritmo di Kahn, che lancia `Circular dependency detected.` sui cicli e restituisce l'ordine **invertito** (dipendenze prima) (core-libs/schematics/src/shared/utils/graph-utils.ts:L85-L135). Il grafo delle librerie usa le dipendenze `@spartacus/*` di `dependencies.json` (core-libs/schematics/src/shared/utils/graph-utils.ts:L137-L166), quello delle feature un arco per ogni `dependencyFeatures` (core-libs/schematics/src/shared/utils/graph-utils.ts:L168-L184); `groupFeatures` avvicina le feature della stessa libreria (core-libs/schematics/src/shared/utils/graph-utils.ts:L51-L69). Le voci assenti dall'ordine finiscono in fondo (core-libs/schematics/src/shared/utils/lib-utils.ts:L878-L891).
3. `addFeatures`. In un'app nuova installa tutte le feature della closure; in un'app esistente solo `options.features` ("we don't want to force-install the dependent features"). Per ciascuna applica `customConfig(options).options` se c'è, accoda `addLibraryFeature` e uno `externalSchematic('@spartacus/schematics', 'wrapper-module', …)` per ogni `importAfter` (core-libs/schematics/src/shared/utils/feature-utils.ts:L102-L154).
4. `addLibraryFeature`. Se manca la struttura fa scaffolding, poi `handleFeature`, stili e assets (core-libs/schematics/src/shared/utils/lib-utils.ts:L239-L273). `handleFeature` crea `<moduleName>-feature.module.ts` in `app/spartacus/features/<folder>`, dichiarato in `spartacus-features`, e aggiunge root mo-

dule, feature module, traduzioni, custom config e, per b2b, `configureB2bFeatures` (core-libs/schematics/src/shared/utils/lib-utils.ts:L293-L326).

5. **Lazy vs eager.** Con `lazy` il feature module diventa `provideConfig(<CmsConfig>{ featureModules: { [CHUNK]: { module: () => import('…').then((m) => m.X) } } })`, altrimenti è importato staticamente (core-libs/schematics/src/shared/utils/lib-utils.ts:L397-L446). Questo è esattamente il formato consumato dal lazy loading descritto in 12.
6. **Traduzioni, stili, assets, B2B.** `addFeatureTranslations` → `provideConfig(<I18nConfig>{…})` (core-libs/schematics/src/shared/utils/lib-utils.ts:L448-L494); `addLibraryStyles` → `<sourceRoot>/styles/spartacus/<file>.scss` aggiunto a `styles` di build e test (core-libs/schematics/src/shared/utils/lib-utils.ts:L641-L728); `addLibraryAssets` → glob `./node_modules/@spartacus/<input>` in `assets` (core-libs/schematics/src/shared/utils/lib-utils.ts:L541-L629); per b2b `provideConfig(defaultB2bOccConfig)` + dipendenza `@spartacus/setup` (core-libs/schematics/src/shared/utils/lib-utils.ts:L786-L841, core-libs/schematics/src/shared/utils/config-utils.ts:L123-L139).

Esempio concreto: `CHECKOUT_BASE_SCHEMATICS_CONFIG` (feature `Checkout`, `CheckoutModule` da `@spartacus/checkout/base`, root `CheckoutRootModule`, chunk `CHECKOUT_FEATURE`, dipendenza da `Order`) e `CHECKOUT_B2B_SCHEMATICS_CONFIG` (`b2b: true`, stesso `moduleName`, `importAfter` per caricare `CheckoutB2BModule` dopo `CheckoutModule`) (core-libs/schematics/src/shared/lib-configs/checkout-schematics-config.ts:L40-L125).

3.5 `wrapper-module`: caricare una feature "dopo" un'altra

Alcune feature (es. Checkout B2B) estendono un'altra feature e devono essere importate **nello stesso chunk lazy, dopo** di essa. Il wrapper risolve il problema creando un modulo che importa staticamente entrambi, e ri-puntando il dynamic import a quel modulo. `generateWrapperModule` è un chain di sei rule (core-libs/schematics/src/wrapper-module/index.ts:L527-L541):

1. `checkWrapperModuleExists` — se un file importa già staticamente il marker module, il suo path finisce in `options.internal.wrapperModulePath`: le rule successive leggono questa **mutazione** delle opzioni (core-libs/schematics/src/wrapper-module/index.ts:L89-L114).
2. `createWrapperModule` — crea `app/spartacus/features/<folder>/<name>-wrapper.module.ts` importandolo temporaneamente nel feature module, workaround perché ts-morph "does not 'see' the newly created TS file if it is not referenced anywhere" (core-libs/schematics/src/wrapper-module/index.ts:L167-L207). Il nome file toglie `module`/`Module` e aggiunge `-wrapper` (core-libs/schematics/src/shared/utils/lib-utils.ts:L328-L331).
3. `updateFeatureModule` — `import('@spartacus/user/profile').then(...)` diventa `import('./profile-wrapper.module').then(...)` e l'import temporaneo è rimosso (core-libs/schematics/src/wrapper-module/index.ts:L222-L336).
4. `removeLibraryDynamicImport` / `cleanupConfig` — toglie `module` dal provider della feature dipendente e, se l'oggetto resta `{}`, l'intero provider (core-libs/schematics/src/wrapper-module/index.ts:L338-L405, core-libs/schematics/src/wrapper-module/index.ts:L413-L427).
5. `updateWrapperModule` ×2 — import statico di marker e poi feature module nel wrapper (core-libs/schematics/src/wrapper-module/index.ts:L457-L521).

Le opzioni comprendono `markerModuleName`, `featureModuleName` e `internal.wrapperModulePath` ("Should not be set by the user") (core-libs/schematics/src/wrapper-module/schema.ts:L9-L38).

3.6 `add-ssr`

`addSSR` riusa lo schematic ufficiale di Angular e poi lo "piega" verso lo stack SSR di Spartacus (`core-libs/schematics/src/add-ssr/index.ts:L437-L465`):

1. dipendenze `@spartacus/setup`, `@angular/platform-server`, `@angular/ssr`, con le versioni prese da `dependencies.json` alla chiave `storefrontapp` (`core-libs/schematics/src/add-ssr/index.ts:L59-L59`, `core-libs/schematics/src/add-ssr/index.ts:L131-L153`);
2. `externalSchematic('@angular/ssr', 'ng-add')`, che a sua volta delega a `@schematics/angular:ssr` (`deps:angular-ssr-21.2.23/package/schematics/ng-add/index.js:L11-L11`);
3. rimozione di `build.options.outputMode` ("This could be removed when we migrate to new SSR API") (`core-libs/schematics/src/add-ssr/index.ts:L362-L412`) e di `app.routes.server.ts` ("not supported by Spartacus SSR") (`core-libs/schematics/src/add-ssr/index.ts:L414-L435`);
4. `scripts["build:ssr"] = "ng build"` per la build CCv2 (TODO CXSPA-6466) (`core-libs/schematics/src/add-ssr/index.ts:L155-L181`);
5. `AppServerModule` vuoto in `app.module.server.ts` (`core-libs/schematics/src/add-ssr/create-app-server-module.ts:L22-L77`); in `app.config.server.ts` rimuove `withRoutes(serverRoutes)` e aggiunge `importProvidersFrom(AppServerModule)` (`core-libs/schematics/src/add-ssr/update-app-config-server.ts:L17-L58`, `core-libs/schematics/src/add-ssr/update-app-config-server.ts:L104-L140`); in `app.module.server.ts` inserisce `...provideServer({ serverRequestOrigin: process.env['SERVER_REQUEST_ORIGIN'] })` da `@spartacus/setup/ssr` (`core-libs/schematics/src/add-ssr/index.ts:L61-L96`);
6. meta OCC in `index.html` e `provideClientHydration(withEventReplay(), withNoHttpTransferCache())` in `appConfig` — transfer cache "temporarily disabled" (CXSPA-10430); il meta `occ-backend-base-url` è aggiunto da `modifyIndexHtmlFile` (`core-libs/schematics/src/add-ssr/index.ts:L98-L117`), l'hydration da `updateAppConfigInSsr` (`core-libs/schematics/src/add-ssr/update-app-config-in-ssr.ts:L47-L77`, `core-libs/schematics/src/add-ssr/update-app-config-in-ssr.ts:L104-L149`). I providers sono individuati cercando una variabile chiamata `appConfig` / `serverConfig` con un object literal che ha `providers` array (`core-libs/schematics/src/add-ssr/get-providers-array-from-named-object.ts:L22-L64`);
7. merge del template `server.ts` con `MergeStrategy.Overwrite` (`core-libs/schematics/src/add-ssr/index.ts:L455-L458`): `NgExpressEngineDecorator.get(ngExpressEngine)`, `getOriginValidationMiddleware`, `index.server.html`, `trust proxy: loopback`, `defaultExpressErrorHandlers` (`core-libs/schematics/src/add-ssr/files/server.__typescriptExt__:L1-L63`), route regex Express 5 e porta di default `4000` (`core-libs/schematics/src/add-ssr/files/server.__typescriptExt__:L45-L73`);
8. `prerender: false`, nuova configurazione `noSsr` agganciata a `serve` production/development (`core-libs/schematics/src/add-ssr/index.ts:L183-L360`); install.

3.7 `add-cms-component`

Valida che `cmsComponentDataModel` sia presente se `cmsComponentData` (`core-libs/schematics/src/add-cms-component/index.ts:L356-L362`); se non viene passato `declareCmsModule` genera un nuovo modulo con `@schematics/angular:module`, poi il componente con `@schematics/angular:component`, quindi aggiorna modulo/componente/template (`core-libs/schematics/src/add-cms-component/index.ts:L398-L447`). La registrazione usa la vecchia API `ConfigModule.withConfig(<CmsConfig>{ cmsComponents: … })` (`core-libs/schematics/src/add-cms-component/index.ts:L114-L136`).

3.8 AI context: `@spartacus/skills` e schematic `ai-context`

1. `@spartacus/skills` (versione `221121.22.0`, nessun target Nx) contiene la sola skill `skills/spartacus-developer` (`SKILL.md` + `references/`) (`core-libs/skills/package.json:L2-L14`, `core-libs/skills/project.json:L1-L7`). `SKILL.md` ha frontmatter `name: spartacus-developer` e una Quick Reference di regole per chi

sviluppa su Spartacus (core-libs/skills/skills/spartacus-developer/SKILL.md:L1-L5, core-libs/skills/skills/spartacus-developer/SKILL.md:L32-L58).

2. Lo schematic `ai-context` normalizza `aiTools` (solo `claude`, `agents`, nell'ordine fisso) e risolve la sorgente: se `SPARTACUS_SKILLS_DIR` è definita viene usata **in esclusiva** (path inesistente → `null` → warning, anche se `@spartacus/skills` è installato) (core-libs/schematics/src/ai-context/index.ts:L85-L88); altrimenti `require.resolve('@spartacus/skills/package.json', { paths: [cwd] })`, poi il fallback `node_modules/@spartacus/skills/skills/spartacus-developer`; se non trova nulla emette un warning ed esce (core-libs/schematics/src/ai-context/index.ts:L41-L111).
3. Legge i file dal **file system reale** (`fs.readdirSync`/`readFileSync`), li ordina e li scrive nel `Tree` (create/overwrite) (core-libs/schematics/src/ai-context/index.ts:L113-L132, core-libs/schematics/src/ai-context/index.ts:L178-L191).
4. Con `deleteBeforeCopy` svuota prima la destinazione e, se resta qualcosa, lancia "so the transactional Tree commit is aborted" (core-libs/schematics/src/ai-context/index.ts:L159-L176).
5. `verifySkillTree` confronta lo SHA-256 di ogni file e rifiuta file extra sotto la destinazione (core-libs/schematics/src/ai-context/index.ts:L193-L254).

3.9 `ng update`: struttura delle migrazioni

1. `ng-update.migrations` punta a `./src/migrations/migrations.json` (core-libs/schematics/package.json:L46-L47). La CLI legge `packageNode['ng-update'].migrations` e chiama `executeMigrations(..., from, options.to || packageNode.version, ...)` (deps:devkit/angular-cli-21.2.23/package/src/commands/update/cli.js:L252-L253, deps:devkit/angular-cli-21.2.23/package/src/commands/update/cli.js:L303-L303); seleziona le voci la cui `version` soddisfa il range `>from <=to` e le esegue in ordine di versione e poi di **nome** (deps:devkit/angular-cli-21.2.23/package/src/commands/update/utilities/migration.js:L107-L118, deps:devkit/angular-cli-21.2.23/package/src/commands/update/utilities/migration.js:L127-L127).
2. `migrations.json` contiene 25 voci: 10 per `2211.19.0`, 4 per `2211.36.0`, 10 per `221121.7.0` e 1 per `221121.22.0` (core-libs/schematics/src/migrations/migrations.json:L3-L127); le chiavi hanno un prefisso `00-`…`09-` per versione (core-libs/schematics/src/migrations/migrations.json:L3-L52): poiché la CLI ordina per versione e poi per nome, è questo prefisso a fissare l'ordine d'esecuzione dentro una stessa versione (deps:devkit/angular-cli-21.2.23/package/src/commands/update/utilities/migration.js:L127-L127).
3. Ogni voce punta a `./<versione>/<nome>/<file>#migrate`. Per le migrazioni "di codice" il `migrate()` per versione è un wrapper sottilissimo che passa i dati generati al mechanism (core-libs/schematics/src/migrations/221121_7/constructor-deprecations/constructor-deprecations.ts:L7-L19).
4. I dati (`data/generated-*.migration.ts`, "Generated file, don't update manually.") sono prodotti da `tools/breaking-changes/generate-*.ts` per `NEW_VERSION = '221121_7'`, con prefisso di commento `// TODO:Spartacus -` (core-libs/schematics/src/migrations/221121_7/constructor-deprecations/data/generated-constructor.migration.ts:L7-L9, tools/breaking-changes/common.ts:L12-L19). Dimensioni dei file dati 221121_7 (`wc -l`, righe totali compresi header e import): 191 costruttori, 350 metodi/proprietà, 306 API rimosse, 17 rename (una sola voce). L'unico rename sposta `cdsTranslationChunksConfig` da `@spartacus/cds` a `@spartacus/cds/assets` (core-libs/schematics/src/migrations/221121_7/rename-symbol/data/generated-rename-symbols.migration.ts:L11-L17).
5. Alcune migrazioni 2211_19 hanno dati vuoti (`config-deprecations`, `dependency-management`, `missing-packages`) (core-libs/schematics/src/migrations/2211_19/config-deprecations/config-deprecations.ts:L11-L11, core-libs/schematics/src/migrations/2211_19/dependency-management/dependency-management.ts:L10-L10, core-libs/schematics/src/migrations/2211_19/missing-packages/missing-

packages.ts:L13-L13); css si limita a un warning con link (core-libs/schematics/src/migrations/2211_19/css/css.ts:L10-L16).

Catalogo delle migrazioni di configurazione (non guidate da dati):

VERSIONE	MIGRAZIONE	COSA FA	RIFERIMENTO
2211.19.0	ssr	solo con legacy server builder: ripristina server.ts.bak, zone.js/dist/zone-node→zone.js/node, @nguniversal/express-engine→@spartacus/setup/ssr, elimina express.tokens.ts	core-libs/schematics/src/migrations/2211_19/ssr/ssr.ts:L11-L15, core-libs/schematics/src/migrations/2211_19/update-ssr/update-ssr-files.ts:L25-L137
2211.19.0	angular-json-styling	riusa createStylePreprocessorOptions()	core-libs/schematics/src/migrations/2211_19/angular-json-styles/angular-json-styles.ts:L7-L14
2211.36.0	ssr	index.html → join(serverDistFolder, 'index.server.html') (se isSsrUsed)	core-libs/schematics/src/migrations/2211_36/ssr/update-ssr/update-server-files.ts:L15-L149
2211.36.0	bootstrap	disinstalla bootstrap (npm/yarn/pnpm) e riscrive gli import verso @spartacus/styles/vendor/bootstrap/scss/*	core-libs/schematics/src/migrations/2211_36/bootstrap/bootstrap.ts:L16-L131, core-libs/schematics/src/migrations/2211_36/bootstrap/replace-bootstrap-imports.ts:L9-L198
2211.36.0	silence-sass-deprecations	silenceDeprecations: ['import']	core-libs/schematics/src/migrations/2211_36/silence-sass-deprecations/silence-sass-deprecations.ts:L14-L32
221121.7.0	angular-config	rimuove build.options.index	core-libs/schematics/src/migrations/221121_7/angular-config/index.ts:L13-L71
221121.7.0	angular-providers	provideBrowserGlobalErrorListeners() in app.module.ts	core-libs/schematics/src/migrations/221121_7/angular-providers/index.ts:L21-L88
221121.7.0	express-v5	express ^5.1.0, '*.*'→/.*\..*/, '*'→/.*/ (solo SSR)	core-libs/schematics/src/migrations/221121_7/ssr/express-v5/index.ts:L59-L109, core-libs/schematics/src/migrations/221121_7/ssr/express-v5/index.ts:L199-L261
221121.7.0	tsconfig-update	rimuove outDir/esModuleInterop/moduleResolution, module: "preserve", files: [] + references	core-libs/schematics/src/migrations/221121_7/tsconfig-update/index.ts:L10-L117
221121.7.0	move-zone-change-detection-to-main	sposta provideZoneChangeDetection da main.ts ad app.module.ts	core-libs/schematics/src/migrations/221121_7/move-zone-change-detection-to-main/index.ts:L11-L22
221121.7.0	build-ssr-script	ri-aggiunge build:ssr (solo SSR)	core-libs/schematics/src/migrations/221121_7/ssr/build-ssr-script/index.ts:L16-L73

VERSIONE	MIGRAZIONE	COSA FA	RIFERIMENTO
221121.22.0	`add-or-update-ai-skills`	living migration delle skill AI	`core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L32-L86`

3.10 I mechanism generici

- **Costruttori** — `migrateConstructorDeprecation` scorre tutti i `.ts` del sourceRoot del primo progetto; per ogni deprecazione candidata aggiunge e poi rimuove parametri, ricaricando il sorgente dopo ogni commit (`core-libs/schematics/src/migrations/mechanism/constructor-deprecations/constructor-deprecations.ts:L22-L79`). Un file è candidato se estende la classe deprecata importata dal path atteso, importa i tipi dei parametri e ha costruttore + `super()` corrispondenti (`core-libs/schematics/src/shared/utils/file-utils.ts:L352-L412`); `addConstructorParam` gestisce anche `@Inject(token)` e aggiorna `super(...)` (`core-libs/schematics/src/shared/utils/file-utils.ts:L532-L611`).
- **Metodi e proprietà** — commento `// TODO:Spartacus - '<old>' has been removed. Please try using '<new>' instead.` sopra gli usi (`core-libs/schematics/src/migrations/mechanism/methods-and-properties-deprecations/methods-and-properties-deprecations.ts:L20-L58`).
- **API rimosse** — commento sopra gli import dei simboli rimossi (`core-libs/schematics/src/migrations/mechanism/removed-public-api-deprecations/removed-public-api-deprecation.ts:L19-L53`).
- **Rename symbol** — mechanism su ts-morph (come `missing-packages`, `core-libs/schematics/src/migrations/mechanism/missing-packages/missing-packages.ts:L9-L9`, `core-libs/schematics/src/migrations/mechanism/missing-packages/missing-packages.ts:L30-L33`): sostituisce la dichiarazione di import (preservando l'alias) e chiama `saveAndFormat` (`core-libs/schematics/src/migrations/mechanism/rename-symbol/rename-symbol.ts:L14-L85`).
- **Config** — commento sopra ogni proprietà `propertyName` in un object literal (`core-libs/schematics/src/migrations/mechanism/config-deprecations/config-deprecation.ts:L17-L39`).
- **Componenti** — commenta nei template gli input/output rimossi e, nelle sottoclassi, le proprietà rimosse, usando `@angular/compiler` passato come parametro (`core-libs/schematics/src/migrations/mechanism/component-deprecations/component-deprecations.ts:L27-L156`). Allo SHA è usato solo dalle migrazioni di test: in `migrations.json` non c'è una migrazione component-deprecations (`core-libs/schematics/src/migrations/test/component-deprecations/component-deprecations.ts:L9-L31`).
- **Dependency management** — aggiorna con `overwrite: true` tutte le deps `@spartacus/*` (tranne `@spartacus/schematics`) secondo `dependencies.json` e installa (`core-libs/schematics/src/migrations/mechanism/dependency-management/dependency-management.ts:L28-L139`).
- **Missing packages** — avvisa se si importa da un pacchetto assente nel `package.json` (`core-libs/schematics/src/migrations/mechanism/missing-packages/missing-packages.ts:L18-L67`).

3.11 Living migration delle skill AI

`add-or-update-ai-skills` ha `version: "221121.22.0"` ma la sua JSDoc spiega che la versione "is updated to match the package version on every release so it always fires" (`core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L22-L31`, `core-libs/schematics/src/migrations/migrations.json:L123-L127`). Dato il range `>from <=to` della CLI, gira in ogni `ng update` che passa da una versione inferiore a quella allineata al pacchetto (allo SHA `221121.22.0`); non gira se `from` è già pari a quella versione (`deps:devkit/angular-cli-21.2.23/package/src/commands/update/utilities/migration.js:L107-L118`).

1. Senza TTY (`stdin.isTTY && stdout.isTTY` falso), se trova skill installate (sentinel `SKILL.md` in `.claude/...` o `.agents/...`) le ri-sincronizza, altrimenti stampa un avviso (`core-libs/schematics/src/migrations/`

add-or-update-ai-skills/index.ts:L33-L48, core-libs/schematics/src/migrations/add-or-update-ai-skills/ai-context.utils.ts:L35-L51).

2. Con TTY chiede `Install/Update … (Y/n)` via `readline`; in update riusa gli strumenti già presenti, altrimenti chiede uno per uno (core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L50-L85, core-libs/schematics/src/migrations/add-or-update-ai-skills/ai-context.utils.ts:L53-L86).
3. `scheduleSkillsDeleteAndCopy` aggiunge `@spartacus/skills` con `overwrite: true`, accoda l'install e poi `RunSchematicTask('@spartacus/schematics', 'ai-context', { aiTools, deleteBeforeCopy: true })` (core-libs/schematics/src/migrations/add-or-update-ai-skills/ai-context.utils.ts:L95-L115).

3.12 Modernize-app (schematics manuali)

Tre schematics da lanciare a mano con `ng generate` per gli upgrade che non si possono automatizzare in sicurezza dentro `ng update`:

- `modernize-app-migrated-from-6_8-to-2211_19`: application builder, tsconfig, app module e, solo con legacy server builder, 8 step SSR (core-libs/schematics/src/modernize-app-migrated-from-6_8-to-2211_19/index.ts:L26-L48);
- `modernize-app-migrated-from-2211_32-to-2211_36` (Angular 19): angular.json, tsconfig, assets e favicon in `public`, `main.ts`, i18n lazy loading, server.ts (core-libs/schematics/src/modernize-app-migrated-from-2211_32-to-2211_36/index.ts:L29-L48);
- `modernize-app-to-standalone-bootstrap-application`: `bootstrapModule(AppModule)` → `bootstrapApplication(AppComponent, appConfig)` (core-libs/schematics/src/modernize-app-to-standalone-bootstrap-application/index.ts:L26-L54), con un `app.config.ts` generato che contiene `provideBrowserGlobalErrorListeners()`, `provideZoneChangeDetection({ eventCoalescing: true })`, `provideHttpClient(...)`, `importProvidersFrom(AppModule)` (core-libs/schematics/src/modernize-app-to-standalone-bootstrap-application/csr-and-ssr/create-app-config.ts:L16-L59).

Ogni step è avvolto in `withFallbackDocs*`: un'eccezione viene loggata con il link alla guida manuale e viene restituito lo stesso `tree` (le modifiche già applicate dallo step prima dell'eccezione non vengono annullate) (core-libs/schematics/src/modernize-app-to-standalone-bootstrap-application/fallback-advice-to-follow-docs.ts:L12-L43, core-libs/schematics/src/modernize-app-to-standalone-bootstrap-application/fallback-advice-to-follow-docs.ts:L32-L41).

3.13 Utility AST: due mondi

Gli schematics usano **due** API di manipolazione del codice:

- **ts-morph** (installazione, wrapper, rename): `createProgram` crea un `Project` dal tsconfig sopra un `TreeFileSystem` che adatta il `Tree` del devkit (core-libs/schematics/src/shared/utils/program.ts:L11-L35); `saveAndFormat` fa `organizeImports()`, `formatText({indentSize: 2})`, `saveSync()` (core-libs/schematics/src/shared/utils/program.ts:L37-L48); `writeFileSync` evita la scrittura se il contenuto è identico (core-libs/schematics/src/shared/utils/tree-file-system.ts:L84-L94). `addModuleImport/Export/Provider` aggiungono agli array di `@NgModule` con un `order` opzionale (core-libs/schematics/src/shared/utils/new-module-utils.ts:L87-L176) e deduplicano con confronto testuale normalizzato (core-libs/schematics/src/shared/utils/new-module-utils.ts:L222-L284, core-libs/schematics/src/shared/utils/config-utils.ts:L52-L84).
- **TypeScript AST "classico"** + `InsertChange/RemoveChange/ReplaceChange` applicati con `UpdateRecorder` in `commitChanges` (core-libs/schematics/src/shared/utils/file-utils.ts:L292-L332): usato da quasi tutti i mechanism di migrazione.

3.14 Schematics delle feature lib

Esistono cartelle `schematics/` in 20 feature-libs e 12 integration-libs (censimento del dossier). Esempio `@spartacus/checkout`: `"schematics": "./schematics/collection.json"`, build `tsc -p ./tsconfig.schematics.json` (feature-libs/checkout/package.json:L21-L23, feature-libs/checkout/package.json:L51-L51), collection con `ng-add` (privato) e `add` su `addCheckoutFeatures` (feature-libs/checkout/schematics/collection.json:L3-L17). `addCheckoutFeatures` valida che `@spartacus/core` sia installato, calcola la closure, poi `analyzeApplication` → `addFeatures` → `addPackageJsonDependenciesForLibrary(peerDependencies)` → `finalizeInstallation` (feature-libs/checkout/schematics/add-checkout/index.ts:L25-L43, core-libs/schematics/src/shared/utils/workspace-utils.ts:L161-L168). Lo schema offre `Checkout`, `Checkout-B2B`, `Checkout-Scheduled-Replenishment` con default `["Checkout"]` (feature-libs/checkout/schematics/add-checkout/schema.json:L24-L33). Lo stesso schema vale per tutte le 32 collection: ogni `*/schematics/collection.json` di feature-libs e integration-libs dichiara sia `"ng-add"` sia `"add"`, e ogni `schematics/add-*/index.ts` chiama `validateSpartacusInstallation` e `finalizeInstallation` (verifica con `grep` su tutti i 32 file, es. feature-libs/checkout/schematics/collection.json:L3-L17, feature-libs/checkout/schematics/add-checkout/index.ts:L25-L43).

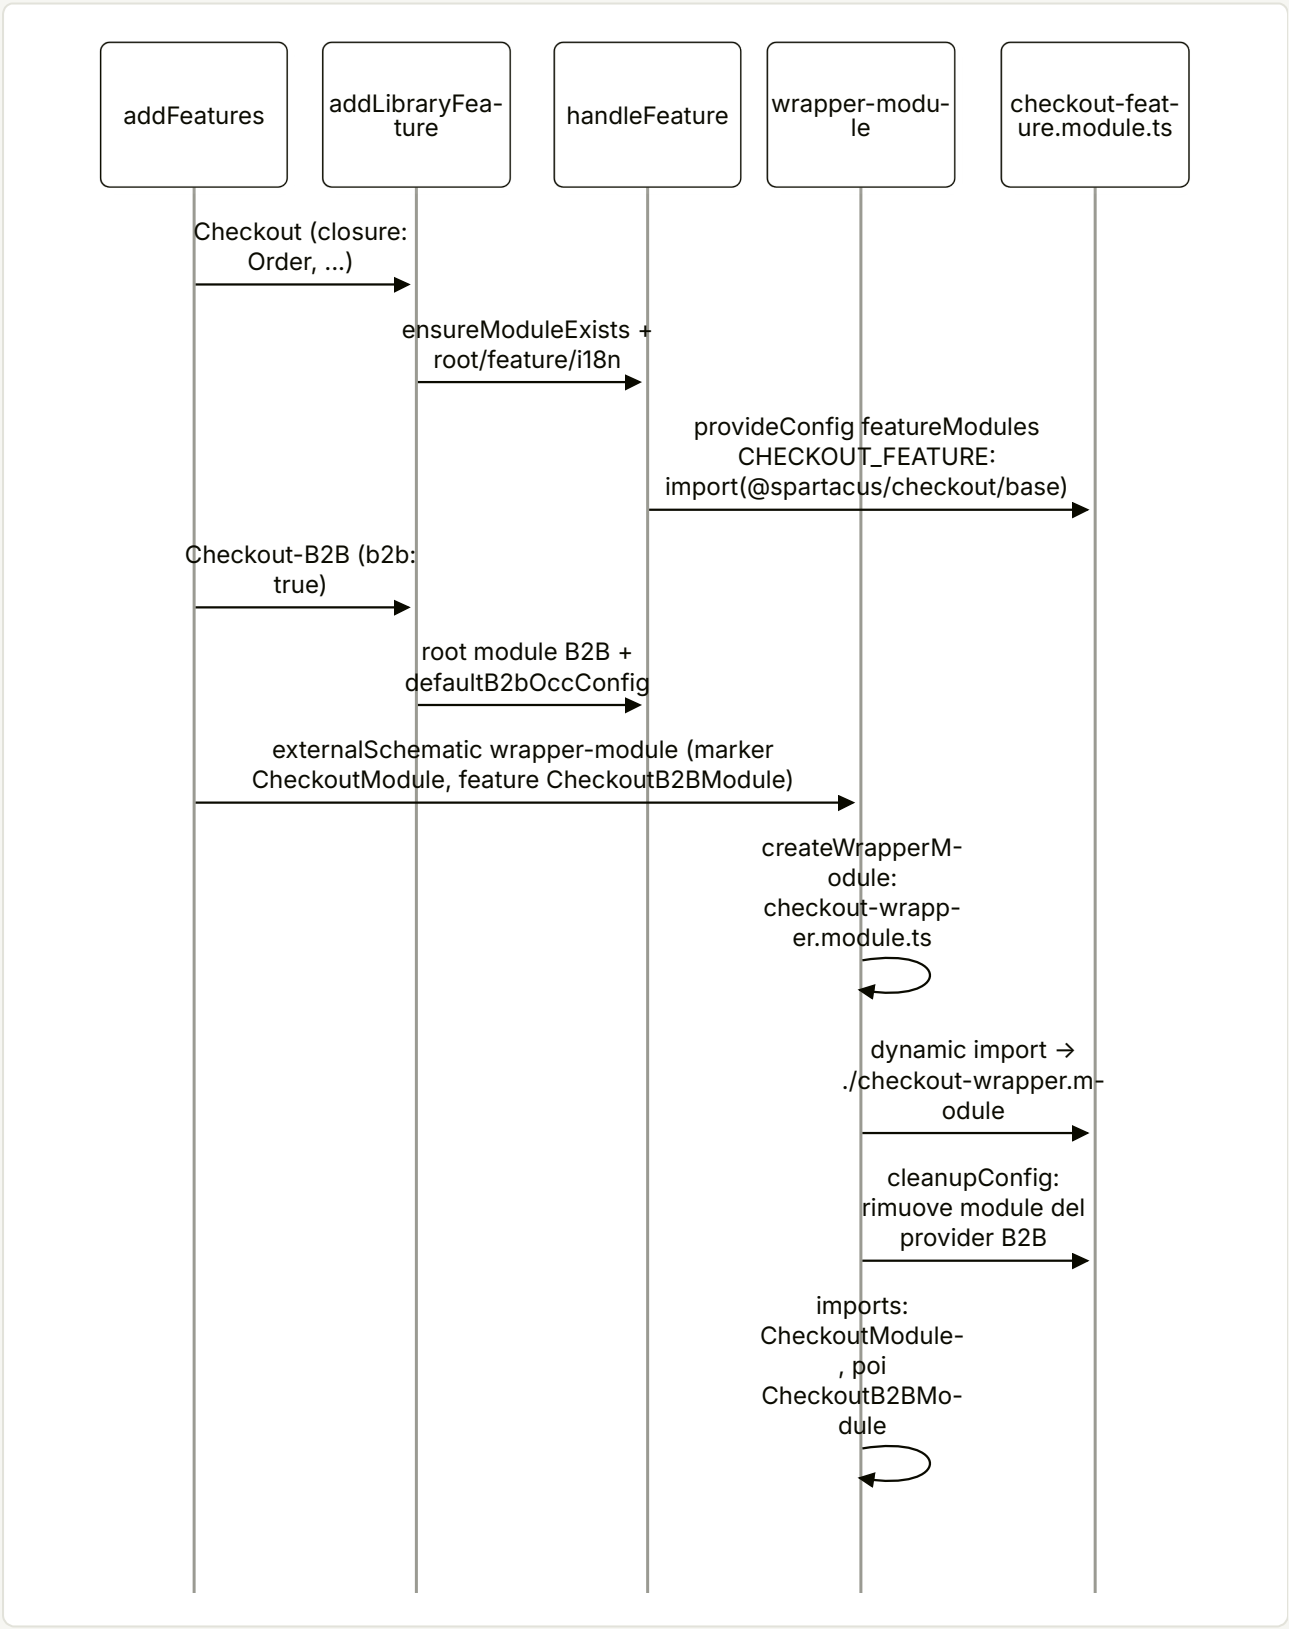
4. Diagrammi

4.1 `ng add @spartacus/schematics` (chain di `add-spartacus`)

■ TAVOLA 43.1 diagramma a tutta pagina, in fondo al capitolo

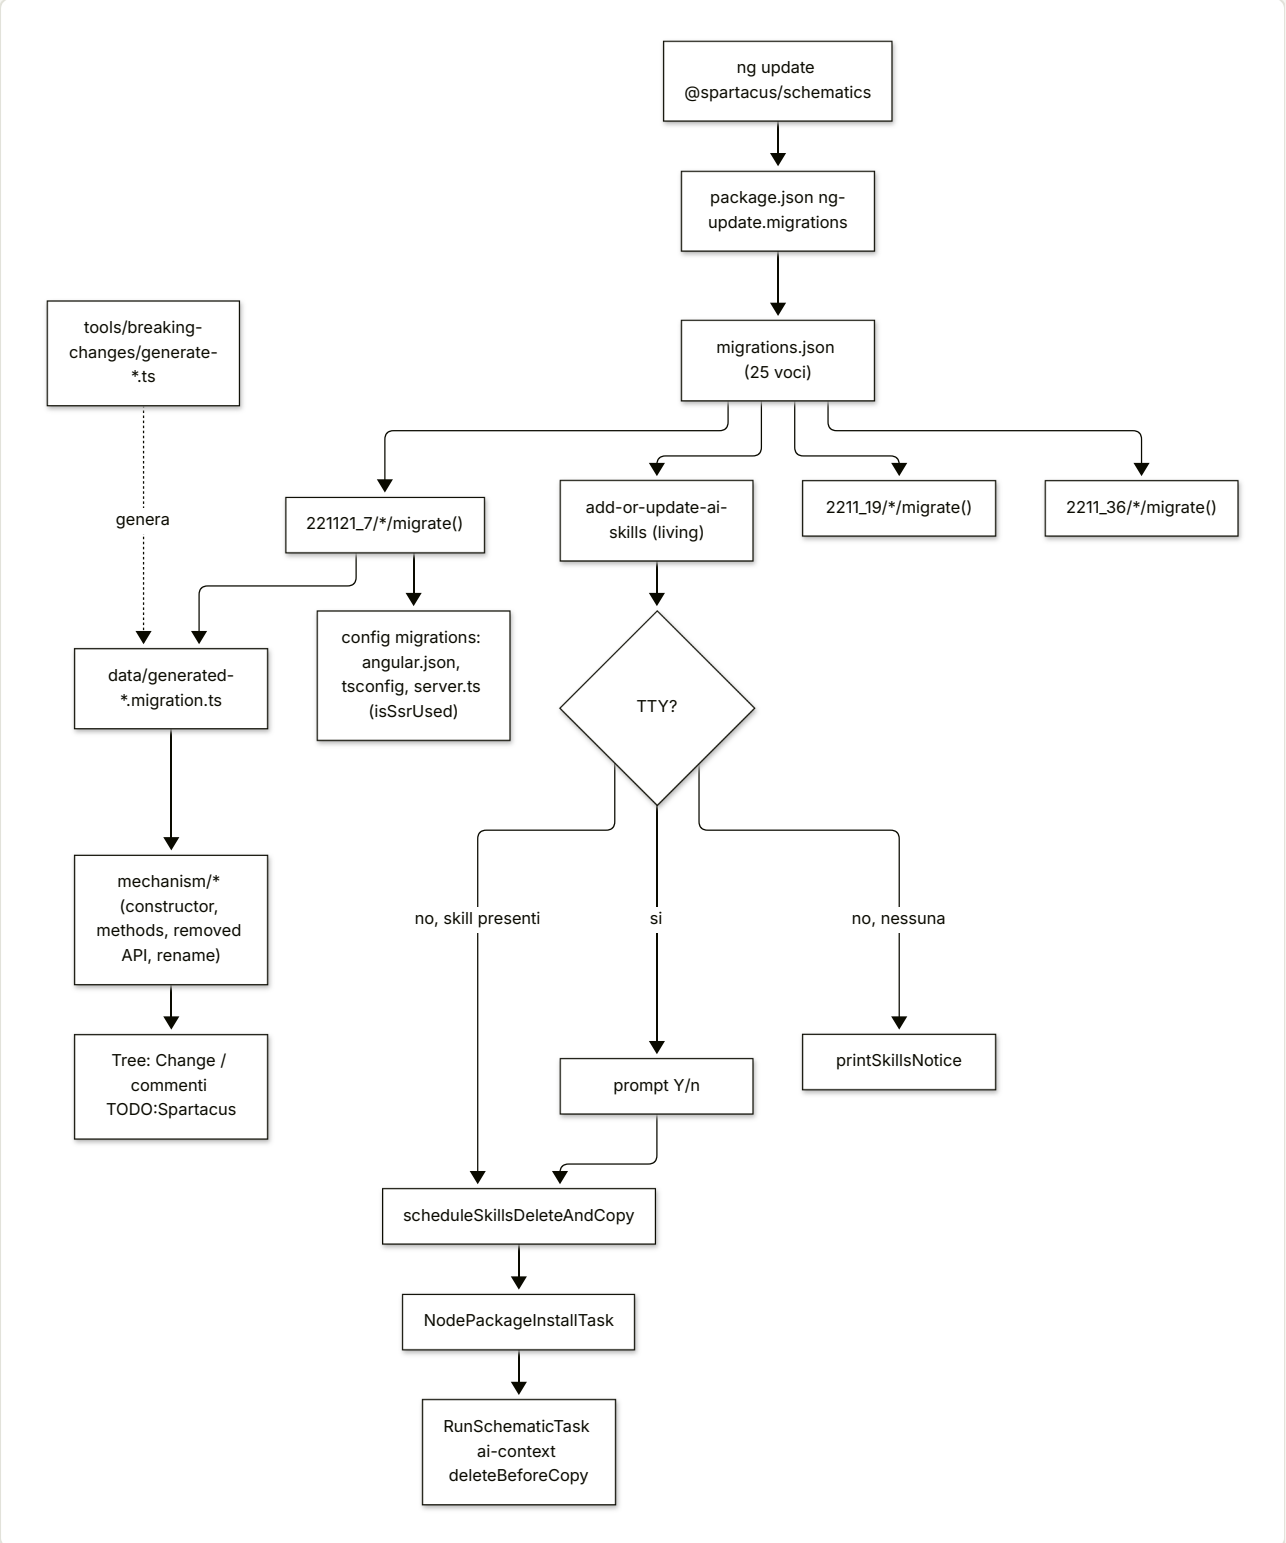
Ogni nodo corrisponde a una rule elencata in §3.3 (core-libs/schematics/src/add-spartacus/index.ts:L531-L590, core-libs/schematics/src/ng-add/index.ts:L17-L24).

4.2 Installazione di una feature con `importAfter` (Checkout-B2B)



Riferimenti: `core-libs/schematics/src/shared/utils/feature-utils.ts:L102-L154`, `core-libs/schematics/src/shared/utils/lib-utils.ts:L293-L326`, `core-libs/schematics/src/shared/lib-configs/checkout-schematics-config.ts:L83-L125`, `core-libs/schematics/src/wrapper-module/index.ts:L527-L541`.

4.3 ng update @spartacus/schematics



Riferimenti: core-libs/schematics/package.json:L46-L47, core-libs/schematics/src/migrations/migrations.json:L3-L127, core-libs/schematics/src/migrations/221121_7/constructor-deprecations/constructor-deprecations.ts:L11-L19, core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L32-L86, tools/breaking-changes/common.ts:L12-L19.

4.4 Schematic `ai-context`

■ **TAVOLA 43.2** diagramma a tutta pagina, in fondo al capitolo

Riferimenti: core-libs/schematics/src/ai-context/index.ts:L41-L254 (risoluzione della sorgente: core-libs/schematics/src/ai-context/index.ts:L84-L111).

---

5. Estratti di codice reale

5.1 ng-add

core-libs/schematics/src/ng-add/index.ts:L17-L24

```ts
export default function (options: SpartacusOptions): Rule {
  return (host: Tree, context: SchematicContext) => {
    return chain([
      schematic('add-spartacus', options),
      options.ssr ? schematic('add-ssr', options) : noop(),
    ])(host, context);
  };
}
```

5.2 La chain di addSpartacus (abbreviata)

core-libs/schematics/src/add-spartacus/index.ts:L531-L590

```ts
export function addSpartacus(options: SpartacusOptions): Rule {
  return (tree: Tree, context: SchematicContext) => {
    const features = analyzeCrossFeatureDependencies(options.features ?? []);
    const dependencies = prepareDependencies(features);
    const spartacusRxjsDependency: NodeDependency[] = [
      dependencies.find((dep) => dep.name === RXJS) as NodeDependency,
    ];
    const packageJsonFile = readPackageJson(tree);
    return chain([
      detectAndSetupAppStructure(options),

      createAppModule(options),
      updateAppConfig(options),
      addStorefrontComponentToAppComponent(options),

      analyzeApplication(options, features),
      // ...
      addFeatures(options, features),

      addAiContext(options),
```

```
      chain([
        addPackageJsonDependencies(
          prepareDependencies(features),
          packageJsonFile
        ),
        /**
         * Force installing versions of dependencies used by Spartacus.
         * E.g. ng13 uses rxjs 7, but Spartacus uses rxjs 6.
         */
        updatePackageJsonDependencies(spartacusRxjsDependency, packageJsonFile),
        installPackageJsonDependencies(),
        replaceCaretWithTildeForSpartacusDependencies(options),
      ]),

      scheduleAiContext(options),

      finalizeInstallation(options, features),
    ])(tree, context);
  };
}
```

5.3 Feature toggle tutti a `true`, letti dal file copiato

core-libs/schematics/src/add-spartacus/spartacus-feature-toggles.ts:L80-L113

```ts
function createFeatureTogglesProvider(): string {
  const defaultFeatureToggles = getDefaultFeatureToggles();

  //for each key in `defaultFeatureToggles` map it to a key with value true
  const featureTogglesAllEnabled: Record<string, boolean> = Object.keys(
    defaultFeatureToggles
  ).reduce((acc, key) => ({ ...acc, [key]: true }), {});
  // ...
  return `provideFeatureToggles(${featureTogglesString})`;
}
// ...
function getDefaultFeatureToggles(): Record<string, boolean> {
  const { defaultFeatureToggles } = require(
    FEATURE_TOGGLES_COPIED_FROM_CORE_LIB_PATH
  );
  return defaultFeatureToggles;
}
```

5.4 addFeatures

core-libs/schematics/src/shared/utils/feature-utils.ts:L115-L152

```ts
/**
 * In an existing Spartacus application, we don't want to
 * force-install the dependent features.
 */
const featuresToInstall = options.internal?.existingSpartacusApplication
  ? (options.features ?? [])
  : features;

const rules: Rule[] = [];
for (const feature of featuresToInstall) {
  const schematicsConfiguration =
    featureSchematicConfigMapping.get(feature);
  // ...
  // TODO:#schematics - fix the interactivity for the CDS / ASM, etc.
  const libraryOptions =
    schematicsConfiguration.customConfig?.(options).options ?? options;

  rules.push(addLibraryFeature(libraryOptions, schematicsConfiguration));

  const wrappers = analyzeWrappers(schematicsConfiguration, libraryOptions);
  for (const { wrapperOptions } of wrappers) {
    rules.push(
      externalSchematic(
        SPARTACUS_SCHEMATICS,
        'wrapper-module',
        wrapperOptions
      )
    );
  }
}

return chain(rules);
```

5.5 Generazione del provider lazy

core-libs/schematics/src/shared/utils/lib-utils.ts:L401-L434

```ts
const configFeatures = ([] as Module[]).concat(config.featureModule);
for (let i = 0; i < configFeatures.length; i++) {
  const featureModule = configFeatures[i];

  // if it's already in a wrapper module
  if (findFeatureModule(featureModule, appSourceFiles)) {
    break;
  }

  let content = `${PROVIDE_CONFIG_FUNCTION}(<${CMS_CONFIG}>{
        featureModules: {`;
```

```
    if (options.lazy) {
      let lazyLoadingChunkName = config.moduleName;
      if (config.lazyLoadingChunk) {
        const namedImportsContent = config.lazyLoadingChunk.namedImports[i];
        lazyLoadingChunkName = `[${namedImportsContent}]`;
        createImports(sourceFile, config.lazyLoadingChunk);
      }
      content =
        content +
        `${lazyLoadingChunkName}: {
              module: () =>
                import('${featureModule.importPath}').then((m) => m.${featureModule.name}),
            },`;

      addModuleProvider(sourceFile, {
        // ...
        content: content + `})`,
      });
```

5.6 `SchematicConfig` di Checkout B2B

core-libs/schematics/src/shared/lib-configs/checkout-schematics-config.ts:L83-L125

```ts
export const CHECKOUT_B2B_SCHEMATICS_CONFIG: SchematicConfig = {
  library: {
    featureName: CHECKOUT_B2B_FEATURE_NAME,
    mainScope: SPARTACUS_CHECKOUT,
    featureScope: SPARTACUS_CHECKOUT_B2B,
    b2b: true,
  },
  folderName: CHECKOUT_FOLDER_NAME,
  moduleName: CHECKOUT_BASE_MODULE_NAME,
  featureModule: {
    name: CHECKOUT_B2B_MODULE,
    importPath: SPARTACUS_CHECKOUT_B2B,
  },
  // ...
  dependencyFeatures: [
    ORDER_FEATURE_NAME,
    CHECKOUT_BASE_FEATURE_NAME,
    USER_PROFILE_FEATURE_NAME,
  ],
  importAfter: [
    {
      markerModuleName: CHECKOUT_BASE_MODULE,
      featureModuleName: CHECKOUT_B2B_MODULE,
```

```
    },
  ],
};
```

5.7 Algoritmo di Kahn

core-libs/schematics/src/shared/utils/graph-utils.ts:L108-L134

```ts
  // Create a queue which stores the vertex without dependencies
  const queue = vertices.filter((vertex) => !inDegree[vertex]);
  const topNums: Record<string, number> = {};
  let index = 0;

  while (queue.length) {
    const vertex = queue.shift();
    // ...
    topNums[vertex] = index;
    index += 1;
    // adjust the incoming degree of its neighbors
    for (const neighbor of graph.getAdjacentVertices()[vertex]) {
      inDegree[neighbor]--;
      if (inDegree[neighbor] === 0) {
        queue.push(neighbor);
      }
    }
  }

  if (index !== vertices.length) {
    throw new Error(`Circular dependency detected.`);
  }

  return Object.keys(topNums).reverse();
```

5.8 Il chain di `generateWrapperModule`

core-libs/schematics/src/wrapper-module/index.ts:L527-L541

```ts
export function generateWrapperModule(options: SpartacusWrapperOptions): Rule {
  return (_tree: Tree, _context: SchematicContext): Rule => {
    return chain([
      checkWrapperModuleExists(options),

      createWrapperModule(options),

      updateFeatureModule(options),
      removeLibraryDynamicImport(options),
```

```
      updateWrapperModule(options, options.markerModuleName),
      updateWrapperModule(options, options.featureModuleName),
    ]);
  };
}
```

5.9 addSSR

core-libs/schematics/src/add-ssr/index.ts:L442-L463

```ts
    return chain([
      addPackageJsonDependencies(prepareDependencies(), packageJson),
      externalSchematic(ANGULAR_SSR, 'ng-add', {
        project: options.project,
      }),
      removeOutputModeSupportedOnlyInNewSsrApi(options),
      removeServerRoutesFile(options),
      addBuildSsrScript(options),
      createAppServerModule(options),
      updateAppConfigServer(options),
      modifyAppServerModuleFile(),
      modifyIndexHtmlFile(options),
      updateAppConfigInSsr(options),
      branchAndMerge(
        chain([mergeWith(serverTemplate, MergeStrategy.Overwrite)]),
        MergeStrategy.Overwrite
      ),

      disableSsrAndPrerenderingInAngularJson(options),

      installPackageJsonDependencies(),
    ])(tree, context);
```

5.10 Wrapper per versione + dato generato

core-libs/schematics/src/migrations/221121_7/constructor-deprecations/constructor-deprecations.ts:L7-L19

```ts
import { Rule, SchematicContext, Tree } from '@angular-devkit/schematics';
import { migrateConstructorDeprecation } from '../../mechanism/constructor-deprecations/constructor-deprecations';
import { GENERATED_CONSTRUCTOR_MIGRATIONS } from './data/generated-constructor.migration';

export function migrate(): Rule {
  return (tree: Tree, context: SchematicContext) => {
    return migrateConstructorDeprecation(
      tree,
```

```
      context,
      GENERATED_CONSTRUCTOR_MIGRATIONS
    );
  };
}
```

core-libs/schematics/src/migrations/221121_7/constructor-deprecations/data/generated-constructor.migration.ts:L7-L29

```ts
//
// Generated file, don't update manually.
//
import { ConstructorDeprecation } from '../../../../shared/utils/file-utils';

export const GENERATED_CONSTRUCTOR_MIGRATIONS: ConstructorDeprecation[] = [
  {
    class: 'EntitySuccessAction',
    importPath: '@spartacus/core',
    deprecatedParams: [
      {
        className: 'string',
        importPath: '',
      },
      // ...
      {
        className: 'any | undefined',
        importPath: '',
      },
    ],
```

5.11 Mechanism costruttori

core-libs/schematics/src/migrations/mechanism/constructor-deprecations/constructor-deprecations.ts:L29-L58

```ts
  const project = getSourceRoot(tree, {});
  const sourceFiles = getAllTsSourceFiles(tree, project);
  for (const originalSource of sourceFiles) {
    const sourcePath = originalSource.fileName;

    for (const constructorDeprecation of constructorDeprecations) {
      if (
        !isCandidateForConstructorDeprecation(
          originalSource,
          constructorDeprecation
        )
      ) {
        continue;
```

```
}

for (const newConstructorParam of constructorDeprecation.addParams ||
  []) {
  // 'source' has to be reloaded after each committed change
  const source = getTsSourceFile(tree, sourcePath);
  const nodes = getSourceNodes(source);
  const constructorNode = findConstructor(nodes);

  const changes = addConstructorParam(
    source,
    sourcePath,
    constructorNode,
    newConstructorParam
  );
  commitChanges(tree, sourcePath, changes, InsertDirection.RIGHT);
}
```

5.12 Mechanism rename symbol (ts-morph)

core-libs/schematics/src/migrations/mechanism/rename-symbol/rename-symbol.ts:L40-L80

```ts
        if (renamedSymbol) {
          const newNodeName = renamedSymbol.newNode
            ? renamedSymbol.newNode
            : importName;

          const oldAlias = namedImport.getAliasNode()?.getText();
          let importPath = renamedSymbol.previousImportPath;

          if (renamedSymbol.newImportPath) {
            importPath = renamedSymbol.newImportPath;
          }

          if (!oldAlias && renamedSymbol.newNode) {
            namedImport.renameAlias(newNodeName);
          }
          // ...
          if ((id.getImportClause()?.getNamedImports()?.length || 0) > 1) {
            namedImport.remove();
          } else {
            id.remove();
          }
        }
      });
});

if (importDeclarationStructures.length) {
```

```
        sourceFile.addImportDeclarations(importDeclarationStructures);

        // organizeImports will remove unused imports
        saveAndFormat(sourceFile);
      }
```

5.13 Living migration AI (ramo non interattivo)

core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L32-L48

```ts
export function migrate(): Rule {
  return async (tree: Tree, context: SchematicContext): Promise<void> => {
    if (!isInteractiveTerminal()) {
      const existingTools = detectInstalledTools(tree);
      if (existingTools.length > 0) {
        // CI / non-interactive: deterministically re-sync the skills that are
        // already present. The delete + copy + integrity verify is idempotent,
        // so this keeps automated `ng update` runs from silently drifting.
        scheduleSkillsDeleteAndCopy(tree, context, existingTools);
        context.logger.info('Re-syncing existing Spartacus AI skills…');
      } else {
        // Nothing installed yet — we can't guess a tool without a prompt, so
        // fall back to the manual-install notice.
        printSkillsNotice(context);
      }
      return;
    }
```

5.14 Copia e verifica delle skill

core-libs/schematics/src/ai-context/index.ts:L140-L157

```ts
function copySkill(
  tree: Tree,
  files: SkillFile[],
  target: AiTool,
  options?: CopyOptions
): void {
  const dest = SKILL_DEST[target];
  if (options?.deleteBeforeCopy) {
    deleteSkillDir(tree, dest);
  }
  writeSkillTree(tree, files, dest);
  verifySkillTree(tree, files, dest);
  if (options?.debug) {
    options.logger?.info(
      `✅ Verified ${files.length} skill file(s) at ${dest}.`
```

```
    );
  }
}
```

5.15 Fallback dei modernize

core-libs/schematics/src/modernize-app-to-standalone-bootstrap-application/fallback-advice-to-follow-docs.ts:L31-L43

```ts
export function withFallbackDocsForStandaloneBootstrap(rule: Rule): Rule {
  return (tree: Tree, context: SchematicContext) => {
    try {
      return rule(tree, context);
    } catch (error) {
      printErrorWithDocsForStandaloneBootstrap(
        error instanceof Error ? error.message : 'Unknown error',
        context
      );
      return tree;
    }
  };
}
```

5.16 Schematics di una feature lib

feature-libs/checkout/schematics/add-checkout/index.ts:L25-L43

```ts
export function addCheckoutFeatures(options: SpartacusCheckoutOptions): Rule {
  return (tree: Tree, _context: SchematicContext): Rule => {
    const packageJson = readPackageJson(tree);
    validateSpartacusInstallation(packageJson);

    const features = analyzeCrossFeatureDependencies(
      options.features as string[]
    );

    return chain([
      analyzeApplication(options, features),

      addFeatures(options, features),
      addPackageJsonDependenciesForLibrary(peerDependencies, options),

      finalizeInstallation(options, features),
    ]);
  };
}
```

6. Configurazione

Opzioni degli schematics (path relativi alla root del repo):

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
`features`	string[]	16 feature (ASM … User-Profile)	core-libs/schematics/src/add-spartacus/schema.json:L14-L34	core-libs/schematics/src/add-spartacus/index.ts:L533-L533
`lazy`	boolean	`true`	core-libs/schematics/src/add-spartacus/schema.json:L338-L342	core-libs/schematics/src/shared/utils/lib-utils.ts:L412-L412

7. Commenti e note notevoli dal sorgente

- "it exports utils for other Spartacus libs' schematics, but is not intended as a public API for external use. It may change without deprecation." — core-libs/schematics/index.ts:L9-L10.
- `@deprecated - features level is no longer used` — core-libs/schematics/src/add-spartacus/schema.ts:L19-L22, core-libs/schematics/src/add-spartacus/configuration.ts:L233-L235.
- Motivazione ^→~: "since 2211.19 we agreed to break SemVer and release breaking changes in 'minor' (x.Y.z) versions" — core-libs/schematics/src/add-spartacus/index.ts:L482-L489.
- "Force installing versions of dependencies used by Spartacus. E.g. ng13 uses rxjs 7, but Spartacus uses rxjs 6." — commento datato, core-libs/schematics/src/add-spartacus/index.ts:L578-L581.
- "Since v17 Angular `ng new` command by default creates a local `AppRoutingModule` file in the project. So we have to replace it." — core-libs/schematics/src/add-spartacus/update-app-module.ts:L75-L78.
- `TODO: CXSPA-6466 Can be removed if Model T adjust their build process to not require this script.` — core-libs/schematics/src/add-ssr/index.ts:L158-L158, core-libs/schematics/src/migrations/221121_7/ssr/build-ssr-script/index.ts:L22-L22.
- "This could be removed when we migrate to new SSR API." — core-libs/schematics/src/add-ssr/index.ts:L365-L365.
- "Http Transfer Cache is temporarily disabled; https://jira.tools.sap/browse/CXSPA-10430" — core-libs/schematics/src/add-ssr/update-app-config-in-ssr.ts:L48-L48.
- `CXSPA-447: Eventually we should remove all the @import directives … and drop the usage of Bootstrap 4` — core-libs/schematics/src/shared/utils/workspace-utils.ts:L223-L224.
- `TODO:#schematics - fix the interactivity for the CDS / ASM, etc.` — core-libs/schematics/src/shared/utils/feature-utils.ts:L134-L134.
- Workaround ts-morph per file nuovi non referenziati — core-libs/schematics/src/wrapper-module/index.ts:L196-L203.
- "Angular CLI auto-kebab-cases camelCase schema props (aiTools → ai-tools) and refuses comma-separated values for array flags — repeat the flag once per value." — core-libs/schematics/src/ai-context/index.ts:L37-L39.
- "Living migration that runs on every `ng update @spartacus/schematics`…" — core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L22-L31.
- `// NOSONAR typescript:S4158` su un loop sopra un array vuoto — core-libs/schematics/src/migrations/2211_19/missing-packages/missing-packages.ts:L17-L17.
- `as any` per non introdurre la dipendenza da `@angular-devkit/build-angular` — core-libs/schematics/src/migrations/221121_7/angular-config/index.ts:L34-L35.
- "*Must* be updated when adding a new schematics library or a feature." — core-libs/schematics/src/shared/schematics-config-mappings.ts:L99-L103.
- "Generated file, don't update manually." — es. core-libs/schematics/src/migrations/221121_7/constructor-deprecations/data/generated-constructor.migration.ts:L7-L9.
- `NEW_VERSION = '221121_7'; // Increment this number to match the current release for which the script is used.` — tools/breaking-changes/common.ts:L12-L12.
- La JSDoc di `isCandidateForConstructorDeprecation` cita parametri (`inheritedClass`, `parameterClassTypes`) non più presenti nella firma — core-libs/schematics/src/shared/utils/file-utils.ts:L352-L368.
- La `description` di `01-migration-v2211_36-ssr` dice `index.server.ts`, ma il codice scrive `index.server.html` — core-libs/schematics/src/migrations/migrations.json:L58-L62, core-libs/schematics/src/migrations/2211_36/ssr/update-ssr/update-server-files.ts:L15-L149.

8. Extension point

Tutto ciò che segue è esportato dal barrel di `@spartacus/schematics` (core-libs/schematics/index.ts:L12-L13 → core-libs/schematics/src/shared/index.ts:L7-L10), che però si dichiara **non stabile**. Usarlo dentro schematics propri è legittimo, ma va trattato come API interna in un upgrade (vedi 54 — API pubblica vs interna e upgrade).

EXTENSION POINT	USO	RIFERIMENTO
Schematic `add-spartacus` / `ng-add` con opzioni (`features`, `lazy`, `baseUrl`, `ssr`, `theme`, `aiTools`…)	installazione parametrica	core-libs/schematics/src/add-spartacus/schema.ts:L9-L27
`ng add @spartacus/<lib> --features=…`	installare feature in un'app esistente	feature-libs/checkout/schematics/add-checkout/index.ts:L25-L43
`SchematicConfig` + `addLibraryFeature` / `addFeatures` / `analyzeApplication` / `finalizeInstallation` / `addPackageJsonDependenciesForLibrary`	scrivere lo schematic `ng add` di una **propria** feature lib nello stesso formato di Spartacus	core-libs/schematics/src/shared/utils/lib-utils.ts:L115-L273, core-libs/schematics/src/shared/utils/feature-utils.ts:L102-L154, core-libs/schematics/src/shared/utils/feature-utils.ts:L279-L370, core-libs/schematics/src/shared/utils/lib-utils.ts:L897-L909, core-libs/schematics/src/shared/utils/lib-utils.ts:L763-L777
`customConfig` (`AdditionalFeatureConfiguration` / `AdditionalProviders`)	provider extra nel feature module, override delle opzioni	core-libs/schematics/src/shared/utils/feature-utils.ts:L60-L80
`importAfter` + schematic `wrapper-module`	caricare una propria estensione nello stesso chunk di una feature Spartacus, dopo di essa	core-libs/schematics/src/shared/lib-configs/checkout-schematics-config.ts:L119-L124, core-libs/schematics/src/wrapper-module/index.ts:L527-L541
Utility ts-morph: `addModuleImport`, `addModuleExport`, `addModuleProvider`, `ensureModuleExists`, `createImports`, `createProgram`, `saveAndFormat`	manipolare `@NgModule` e import in schematics propri	core-libs/schematics/src/shared/utils/new-module-utils.ts:L40-L176, core-libs/schematics/src/shared/utils/import-utils.ts:L134-L177, core-libs/schematics/src/shared/utils/program.ts:L11-L48
Tipi di deprecazione (`ConstructorDeprecation`, `MethodPropertyDeprecation`, `DeprecatedNode`, `ConfigDeprecation`, `RenamedSymbol`, `ComponentData`)	descrivere migrazioni di una propria libreria nello stesso formato	core-libs/schematics/src/shared/utils/file-utils.ts:L41-L117
Schematic `add-cms-component`	scaffolding di un componente CMS	core-libs/schematics/src/add-cms-component/index.ts:L398-L447
Schematic `ai-context` + env `SPARTACUS_SKILLS_DIR`	copiare una skill da una sorgente alternativa	core-libs/schematics/src/ai-context/index.ts:L84-L111
`generateDefaultWorkspace`	harness di test per gli spec degli schematics di feature lib	core-libs/schematics/src/shared/utils/generate-default-workspace.ts:L45-L80

Ricette pertinenti della Parte III:

- creare una feature lib lazy-loaded che segua lo stesso formato (`featureModules`, root module, i18n, stili) prodotto da `addLibraryFeature`: 53 — Ricette: feature lib lazy, carrello/checkout, stili, traduzioni;

- registrare componenti CMS (alternativa moderna a `ConfigModule.withConfig` generato da `add-cms-component`): 51 — Ricette: componenti CMS, outlet, route e layout;
- `provideConfig` e ordine dei provider nei moduli generati: 50 — Ricette: configurazione, DI, interceptor, eventi;
- cosa si rompe negli upgrade, ruolo di `ng update` e dei commenti `TODO:Spartacus`: 54 — API pubblica vs interna, upgrade, anti-pattern, checklist.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. `ng add` **cancella il contenuto di** `app.component.html` (default `overwriteAppComponent: true`) e **sostituisce l'array** `imports` di `AppComponent` (`removeOldImports: true`), perdendo ad esempio `RouterOutlet` (core-libs/schematics/src/add-spartacus/index.ts:L215-L217, core-libs/schematics/src/add-spartacus/add-storefront-component-to-app-component.ts:L46-L48).
2. **Tutti i feature toggle a** `true`**.** Le app nuove non partono dai default di core ma con ogni toggle attivo (core-libs/schematics/src/add-spartacus/spartacus-feature-toggles.ts:L77-L93). Vedi 42.
3. **Solo app standalone con naming 2016.** Se tra i sorgenti del primo tsconfig di build non c'è un file il cui path contiene `app.config.ts`, oppure uno che contiene `app.component.ts`, l'installazione si interrompe con il consiglio di rigenerare l'app (core-libs/schematics/src/add-spartacus/index.ts:L324-L369).
4. **Primo progetto di** `angular.json`**.** `getDefaultProjectNameFromWorkspace` restituisce `Object.keys(workspace.projects)[0]`; molte migrazioni chiamano `getSourceRoot(tree, {})` e quindi lavorano solo su quel progetto in un workspace multi-progetto (core-libs/schematics/src/shared/utils/workspace-utils.ts:L111-L115, core-libs/schematics/src/shared/utils/workspace-utils.ts:L33-L49). `getSourceRoot` inoltre **muta** `options.project` (core-libs/schematics/src/shared/utils/workspace-utils.ts:L39-L41).
5. **Migrazioni "a commento" non idempotenti.** Config, metodi/proprietà e API rimosse inseriscono il commento senza controllare se c'è già: rilanciarle duplica i `// TODO:Spartacus` (core-libs/schematics/src/migrations/mechanism/config-deprecations/config-deprecation.ts:L24-L35, core-libs/schematics/src/shared/utils/file-utils.ts:L1145-L1171); lo stesso vale per `insertCommentAboveIdentifier` (metodi/proprietà) e `insertCommentAboveImportIdentifier` (API rimosse) (core-libs/schematics/src/shared/utils/file-utils.ts:L1173-L1203, core-libs/schematics/src/migrations/mechanism/methods-and-properties-deprecations/methods-and-properties-deprecations.ts:L33-L42, core-libs/schematics/src/shared/utils/file-utils.ts:L1235-L1242, core-libs/schematics/src/migrations/mechanism/removed-public-api-deprecations/removed-public-api-deprecation.ts:L34-L44).
6. **Doppio prefisso nei commenti delle API rimosse.** Il generatore mette già `// TODO:Spartacus -` nel `comment` dei dati, e il mechanism lo avvolge ancora con `// TODO:Spartacus :` con `TODO_SPARTACUS = 'TODO:Spartacus -'` il risultato atteso è `// TODO:Spartacus - // TODO:Spartacus - Variable …` (tools/breaking-changes/generate-deleted.ts:L58-L58, core-libs/schematics/src/migrations/221121_7/removed-public-api-deprecations/data/generated-removed-public-api.migration.ts:L15-L16, core-libs/schematics/src/migrations/mechanism/removed-public-api-deprecations/removed-public-api-deprecation.ts:L39-L53, core-libs/schematics/src/shared/constants.ts:L1145-L1145). DA VERIFICARE: inferito dalla lettura del codice, nessuno spec esegue il mechanism sui dati generati.
7. **Match di import per sottostringa.** `insertCommentAboveImportIdentifier` filtra con `.includes(importPath)`: `@spartacus/cart` corrisponde anche a `@spartacus/cart/base` (core-libs/schematics/src/shared/utils/file-utils.ts:L1205-L1217).
8. **Due install task.** Con `aiTools` valorizzato `add-spartacus` accoda un `NodePackageInstallTask` in `installPackageJsonDependencies()` e un altro in `scheduleAiContext` (core-libs/schematics/src/add-

spartacus/index.ts:L583-L587, core-libs/schematics/src/add-spartacus/ai-context.ts:L61-L61). Il devkit non li deduplica: `TaskScheduler.schedule` accoda ogni task con un id nuovo ed `executePostTasks` li esegue tutti in sequenza, quindi l'install gira due volte (deps:devkit/angular-devkit-schematics-21.2.23/package/src/engine/engine.js:L117-L130, deps:devkit/angular-devkit-schematics-21.2.23/package/src/engine/engine.js:L283-L297).

9. `ai-context` **manuale dopo un** `npm update`**.** Senza `deleteBeforeCopy` (opzione interna, non nello schema JSON) la destinazione non viene svuotata, ma `verifySkillTree` rifiuta comunque file "extra": se la nuova versione di `@spartacus/skills` ha rimosso un file, `ng g @spartacus/schematics:ai-context` fallisce con "unexpected file(s)", proprio nel caso d'uso suggerito dal log di `ng add` ("Re-run 'ng generate @spartacus/schematics:ai-context' anytime to refresh them after updating the package") (core-libs/schematics/src/ai-context/index.ts:L146-L151, core-libs/schematics/src/ai-context/index.ts:L241-L253, core-libs/schematics/src/add-spartacus/ai-context.ts:L71-L74). Il "copy step" del README è invece il `cp -r` manuale, che allo stesso modo non rimuove i file obsoleti (core-libs/skills/README.md:L50-L55, core-libs/skills/README.md:L58-L61). La via robusta è `ng update`, che passa `deleteBeforeCopy: true` (core-libs/schematics/src/migrations/add-or-update-ai-skills/ai-context.utils.ts:L108-L114).
10. **JSDoc contraddittorie sull'AI context.** L'esempio mostra `--ai-tools=cursor`, ma lo schema accetta solo `agents`/`claude`: da CLI il comando viene rifiutato dalla validazione dello schema (`InvalidInputOptions`) prima di arrivare alla factory; `normalize` scarta valori non supportati solo nelle invocazioni programmatiche (`RunSchematicTask`, `add-spartacus`) (core-libs/schematics/src/ai-context/index.ts:L35-L35, core-libs/schematics/src/ai-context/schema.json:L7-L13, deps:devkit/angular-devkit-schematics-21.2.23/package/tools/schema-option-transform.js:L27-L31, core-libs/schematics/src/ai-context/index.ts:L256-L267); la living migration dice che in CI "falls back to a printed notice", ma se trova skill installate le ri-sincronizza (core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L28-L31, core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L34-L47).
11. `add-ssr` **sovrascrive** `server.ts` con `MergeStrategy.Overwrite`, compreso quello appena generato da `@angular/ssr` (core-libs/schematics/src/add-ssr/index.ts:L455-L458); il template riceve `browserDistDirectory` ma non lo usa (core-libs/schematics/src/add-ssr/index.ts:L119-L129, core-libs/schematics/src/add-ssr/files/server.__typescriptExt__:L19-L20).
12. `"undefined,noSsr"`**.** `useNoSsrConfigurationInNgServe` concatena `${buildTarget},noSsr` anche se `buildTarget` è indefinito (core-libs/schematics/src/add-ssr/index.ts:L336-L343).
13. `modifyIndexHtmlFile` **legge** `src/index.html` **fisso** ma scrive su `getIndexHtmlPath(tree)`: con un `sourceRoot` diverso da `src` il controllo fallisce in silenzio (core-libs/schematics/src/add-ssr/index.ts:L98-L117).
14. **Nome invertito.** `move-zone-change-detection-to-main` sposta `provideZoneChangeDetection` *da* `main.ts` *ad* `app.module.ts` (core-libs/schematics/src/migrations/migrations.json:L93-L97, core-libs/schematics/src/migrations/221121_7/move-zone-change-detection-to-main/index.ts:L11-L16).
15. **Check di duplicato testuali.** `angular-providers` e la migrazione zone controllano con `getFullText().includes(...)`: basta un commento con quel nome per saltare l'aggiunta (core-libs/schematics/src/migrations/221121_7/angular-providers/index.ts:L75-L78, core-libs/schematics/src/migrations/221121_7/move-zone-change-detection-to-main/add-zone-change-detection-to-app-module/index.ts:L86-L90).
16. **Side effect fuori dal Tree.** `2211_36 bootstrap` esegue davvero `npm/yarn/pnpm remove bootstrap` con `spawn(…, { shell: true })` dentro la rule e risolve la promise anche in caso di errore (core-libs/schematics/src/migrations/2211_36/bootstrap/bootstrap.ts:L26-L72). Anche `ai-context` legge le skill dal file system reale e non dal `Tree` (core-libs/schematics/src/ai-context/index.ts:L119-L132): il risultato dipende da ciò che è davvero installato in `node_modules`. Con `--dry-run` il workflow non aggiunge l'`HostSink` e salta i post-task, quindi install e `ai-context` schedulati come task non partono (deps:devkit/

angular-devkit-schematics-21.2.23/package/src/workflow/base.js:L97-L98, deps:devkit/angular-devkit-schematics-21.2.23/package/src/workflow/base.js:L126-L128); invece la rule di uninstallBootstrap restituisce una funzione async che callRuleAsync invoca e attende durante la trasformazione del tree, quindi lo spawn di remove bootstrap gira **anche** con --dry-run (deps:devkit/angular-devkit-schematics-21.2.23/package/src/rules/call.js:L76-L81).

17. **Path hard-coded.** src/styles.scss, src/main.ts, src/app/app.config.ts in bootstrap e modernize (core-libs/schematics/src/migrations/2211_36/bootstrap/bootstrap.ts:L76-L76, core-libs/schematics/src/modernize-app-to-standalone-bootstrap-application/csr-and-ssr/update-main-ts.ts:L23-L23, core-libs/schematics/src/modernize-app-to-standalone-bootstrap-application/csr-and-ssr/create-app-config.ts:L18-L18).
18. withFallbackDocs* **cattura solo eccezioni sincrone** della rule avvolta (core-libs/schematics/src/modernize-app-to-standalone-bootstrap-application/fallback-advice-to-follow-docs.ts:L31-L43). chain restituisce una funzione async che costruisce osservabili lazy (callRule usa defer) e ritorna () => intermediateTree: se la rule avvolta è una chain, rule(tree, context) restituisce una Promise e gli errori delle rule figlie emergono dopo, fuori dal try sincrono; anche una Promise rifiutata non viene catturata (deps:devkit/angular-devkit-schematics-21.2.23/package/src/rules/base.js:L46-L61, deps:devkit/angular-devkit-schematics-21.2.23/package/src/rules/call.js:L68-L75).
19. **Factory non invocate in** chain**.** updateServerFiles (2211_19) passa removeServer, modifyServerImports, … senza chiamarle (core-libs/schematics/src/migrations/2211_19/update-ssr/update-ssr-files.ts:L25-L32). Funziona comunque: callRuleAsync continua a invocare il risultato finché è una funzione, quindi removeServer(tree, ctx) restituisce la Rule interna, che viene poi eseguita (deps:devkit/angular-devkit-schematics-21.2.23/package/src/rules/call.js:L77-L81). Il codice è fuorviante ma non è un bug.
20. **Bug sottili nell'ordinamento.** groupFeatures usa if (!lastExistingIndex), quindi un indice 0 è trattato come "non trovato" (core-libs/schematics/src/shared/utils/graph-utils.ts:L58-L66); calculateSortInternal con entrambe le voci assenti produce Infinity - Infinity = NaN (core-libs/schematics/src/shared/utils/lib-utils.ts:L890-L890).
21. break **invece di** continue**.** In addToFeatureModule, se un feature module è già presente (es. in un wrapper) il ciclo esce, saltando anche i moduli successivi dell'array (core-libs/schematics/src/shared/utils/lib-utils.ts:L405-L408).
22. isStaticallyImported confronta l'ultimo segmento dopo .: per X.forRoot() diventa forRoot() e non corrisponde al nome del modulo (core-libs/schematics/src/shared/utils/feature-utils.ts:L424-L433).
23. getMajorVersionNumber usa solo il primo carattere: per 221121.22.0 restituisce 2 (core-libs/schematics/src/shared/utils/package-utils.ts:L134-L137).
24. **Dati di deprecazione solo fino a 221121_7.** NEW_VERSION dei generatori è 221121_7; per la 221121.22.0 l'unica migrazione è quella delle skill AI (tools/breaking-changes/common.ts:L12-L12, core-libs/schematics/src/migrations/migrations.json:L123-L127).
25. **Barrel pubblico pesante e incompleto.** generateDefaultWorkspace e test-utils sono esportati, quindi importare @spartacus/schematics carica @angular-devkit/schematics/testing (core-libs/schematics/src/shared/utils/index.ts:L21-L23, core-libs/schematics/src/shared/utils/generate-default-workspace.ts:L7-L10); per contro lib-configs/index.ts non riesporta alcune config (customer-ticketing, estimated-delivery-date, pdf-invoices, pickup-in-store, product-multi-dimensional, requested-delivery-date) e schematics-config-mappings non è esportato (core-libs/schematics/src/shared/lib-configs/index.ts:L7-L21, core-libs/schematics/src/shared/index.ts:L7-L10).
26. add-cms-component **genera API vecchia** (ConfigModule.withConfig) e ha un default cmsComponentDataModelPath discordante fra JSDoc (@spartacus/storefront) e JSON (@spartacus/core) (core-libs/schematics/src/add-cms-component/index.ts:L118-L124, core-libs/schematics/src/add-cms-component/schema.ts:L29-L33).

27. **Versioni e licenze diverse.** `@angular/ssr` è `~21.2.23` nel `package.json` root (quindi in `dependencies.json`) ma `^21.2.23` tra le deps dello schematics (`package.json:L177-L177`, `core-libs/schematics/package.json:L21-L21`); `@spartacus/schematics` è MIT, `@spartacus/skills` e la root Apache-2.0 (`core-libs/schematics/package.json:L11-L11`, `core-libs/skills/package.json:L14-L14`, `package.json:L4-L4`).
28. `prepareDependencies` **calcolato due volte** in `addSpartacus` (`core-libs/schematics/src/add-spartacus/index.ts:L534-L534`, `core-libs/schematics/src/add-spartacus/index.ts:L574-L577`).

---

10. Come fare debug

- `--debug`: quasi ogni rule logga passi e risultati se `options.debug` è `true`, tipicamente con `debugLogRule` (`core-libs/schematics/src/shared/utils/logger-utils.ts:L12-L18`); `addFeatures` stampa anche il "Cross feature graph" calcolato (`core-libs/schematics/src/shared/utils/feature-utils.ts:L107-L113`). Utile per capire perché una feature viene installata (closure delle `dependencyFeatures`).
- **Ordine/dipendenze sbagliati**: controllare `dependencyFeatures` e `importAfter` del `SchematicConfig` e che la config sia in `SCHEMATICS_CONFIGS`; in caso contrario `addFeatures` lancia "[Internal] No feature config found for ..." (`core-libs/schematics/src/shared/utils/feature-utils.ts:L127-L132`). Cicli producono `Circular dependency detected.` (`core-libs/schematics/src/shared/utils/graph-utils.ts:L130-L132`).
- **Feature "dipendente" in un'app esistente**: se manca il marker module `analyzeApplication` lancia con il comando da eseguire, `ng add @spartacus/schematics --features=<marker>` (`core-libs/schematics/src/shared/utils/feature-utils.ts:L279-L370`).
- **Versioni**: le versioni installate vengono da `core-libs/schematics/src/dependencies.json`; dopo una modifica ai `package.json` delle librerie rigenerarlo con `npm run generate:deps` (`package.json:L64-L64`). I log `Upgrading/Downgrading` vengono da `updatePackageJsonDependencies` (`core-libs/schematics/src/shared/utils/package-utils.ts:L296-L335`).
- **Migrazioni che "non fanno nulla"**: molte sono condizionate da `isSsrUsed` / `isUsingLegacyServerBuilder` e loggano lo skip, es. "SSR is not configured - skipping Express 5 migration" (`core-libs/schematics/src/migrations/221121_7/ssr/express-v5/index.ts:L247-L261`, `core-libs/schematics/src/shared/utils/package-utils.ts:L155-L228`). Verificare il builder (`@angular/build:application` o `@angular-devkit/build-angular:application`), `build.options.server` e `ssr.entry`.
- **Mechanism di deprecazione**: un costruttore non migrato di solito non è "candidato" (import della classe da un path diverso, tipi dei parametri non importati, `super()` diverso): rileggere i criteri in `core-libs/schematics/src/shared/utils/file-utils.ts:L352-L412`. Le migrazioni lavorano sul sourceRoot del primo progetto (§9.4).
- **AI skills**: se la copia non avviene cercare il warning "Could not find '@spartacus/skills' in node_modules" (`core-libs/schematics/src/ai-context/index.ts:L51-L59`); per provare una skill locale impostare `SPARTACUS_SKILLS_DIR` (`core-libs/schematics/src/ai-context/index.ts:L85-L88`). Gli errori "Skill integrity check failed" indicano file mancanti/diversi/extra (`core-libs/schematics/src/ai-context/index.ts:L207-L254`).
- **Test**: gli spec sono Jest (`*_spec.ts`, soglie 90/74/90/90) (`core-libs/schematics/jest.schematics.config.js:L8-L13`, `core-libs/schematics/jest.schematics.config.js:L28-L35`). Comandi: `cd core-libs/schematics && npm run test`, `nx run <library-name>:test-jest --testPathPatterns="<spec>"`, `npm run test:all-schematics` (che esegue anche `-u` sugli snapshot) (`.claude/skills/schematics/SKILL.md:L20-L35`, `package.json:L146-L146`); `test-jest-update` aggiorna gli snapshot (`core-libs/schematics/project.json:L20-L26`). Gli spec delle feature lib partono da `generateDefaultWorkspace`, che tiene in cache il tree tra i test (`core-libs/schematics/src/shared/utils/generate-default-workspace.ts:L43-L51`); quelli dei

mechanism usano la collection fittizia `migrations/test/migrations-test.json` (core-libs/schematics/src/migrations/test/migrations-test.json:L1-L49).

- **Modernize**: se uno step fallisce si vedono "NOTA <messaggio>" e il link alla guida manuale, e viene restituito lo stesso `tree`, senza annullare le modifiche parziali già fatte dallo step (core-libs/schematics/src/modernize-app-to-standalone-bootstrap-application/fallback-advice-to-follow-docs.ts:L20-L43).

---

11. Domande di autoverifica

1. **Perché `@spartacus/schematics` può generare `provideFeatureToggles` con tutte le chiavi senza dipendere da `@spartacus/core` a runtime?** Perché uno step di pre-build copia `feature-toggles.ts` in `src/feature-toggles.copied-from-core-lib.ts`, che viene compilato con lo schematics e letto con `require` (core-libs/schematics/copy-feature-toggles.js:L5-L10, core-libs/schematics/src/add-spartacus/spartacus-feature-toggles.ts:L95-L113).
2. **Quali schematics esegue `ng add @spartacus/schematics --ssr`?** `add-spartacus` e poi `add-ssr`, con le stesse opzioni (core-libs/schematics/src/ng-add/index.ts:L17-L24).
3. **Dove finisce un feature module installato in modalità lazy e in che forma?** In `app/spartacus/features/<folder>/<module>-feature.module.ts`, come `provideConfig(<CmsConfig>{ featureModules: { [CHUNK]: { module: () => import(...).then(...) } } })` (core-libs/schematics/src/shared/utils/lib-utils.ts:L293-L326, core-libs/schematics/src/shared/utils/lib-utils.ts:L397-L446).
4. **A cosa serve `importAfter` e cosa produce?** A importare una feature (es. `CheckoutB2BModule`) dopo un'altra (`CheckoutModule`) nello stesso chunk: `addFeatures` lancia `wrapper-module`, che crea `<name>-wrapper.module.ts`, ripunta il dynamic import al wrapper e vi importa staticamente i due moduli in ordine (core-libs/schematics/src/shared/lib-configs/checkout-schematics-config.ts:L119-L124, core-libs/schematics/src/shared/utils/feature-utils.ts:L140-L149, core-libs/schematics/src/wrapper-module/index.ts:L527-L541).
5. **Perché le dipendenze `@spartacus/*` vengono scritte con `~` invece di `^`?** Perché dalla 2211.19 i breaking change possono arrivare nelle versioni "minor"; `replaceCaretWithTildeForSpartacusDependencies` li blocca alla minor (core-libs/schematics/src/add-spartacus/index.ts:L482-L529).
6. **Come è fatta una migrazione di deprecazione costruttori per una nuova release?** `tools/breaking-changes/generate-constructors.ts` scrive `data/generated-constructor.migration.ts` sotto `migrations/<NEW_VERSION>`; un wrapper `migrate()` passa i dati a `migrateConstructorDeprecation`; `migrations.json` registra la voce con la `version` (tools/breaking-changes/common.ts:L12-L19, core-libs/schematics/src/migrations/221121_7/constructor-deprecations/constructor-deprecations.ts:L7-L19, core-libs/schematics/src/migrations/migrations.json:L103-L107).
7. **Perché la migrazione `add-or-update-ai-skills` gira a ogni `ng update`?** Perché è una "living migration": la sua `version` in `migrations.json` viene aggiornata a ogni release (core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L22-L31). La CLI esegue le voci con `version` nel range `>from <=to`, quindi la migrazione gira in ogni `ng update` che parte da una versione inferiore a quella del pacchetto, non se `from` è già pari (deps:devkit/angular-cli-21.2.23/package/src/commands/update/utilities/migration.js:L107-L118).
8. **Cosa succede in CI (senza TTY) durante `ng update` se il progetto ha già `.claude/skills/spartacus-developer/SKILL.md`?** Le skill vengono ri-sincronizzate: `@spartacus/skills` con `overwrite: true`, install, poi `ai-context` con `deleteBeforeCopy: true` (core-libs/schematics/src/migrations/add-or-update-ai-skills/index.ts:L33-L48, core-libs/schematics/src/migrations/add-or-update-ai-skills/ai-context.utils.ts:L95-L115).

9. **Una migrazione Express 5 non ha modificato** `server.ts`**. Prima ipotesi?** L'app non è riconosciuta come SSR da `isSsrUsed` (builder, `build.options.server`, `ssr.entry`, file server non vuoto) e la migrazione esce con il log di skip (`core-libs/schematics/src/migrations/221121_7/ssr/express-v5/index.ts:L247-L261`, `core-libs/schematics/src/shared/utils/package-utils.ts:L193-L228`).
10. **Perché in un workspace con più applicazioni le migrazioni potrebbero non toccare la tua app?** Perché molte usano `getSourceRoot(tree, {})` / `getDefaultProjectNameFromWorkspace`, che sceglie il primo progetto di `angular.json` (`core-libs/schematics/src/shared/utils/workspace-utils.ts:L33-L49`, `core-libs/schematics/src/shared/utils/workspace-utils.ts:L111-L115`).

Riferimenti allo SHA `5b7a1c2bf2808d7380bc20596d10f4fa710c3da1` (vedi 00-meta).

1. A cosa serve e perché esiste

Spartacus è un monorepo Nx con npm workspaces su `feature-libs/*`, `integration-libs/*` e `core-libs/*` (`package.json:L6-L10`). Le librerie sono decine, ognuna pubblicata come pacchetto npm a sé. Per tenerle coerenti servono test a più livelli e un tooling che li orchestri in CI senza far esplodere i tempi. Questo capitolo descrive quel tooling come si presenta allo SHA, che è uno stato **di transizione**:

- **tre runner di unit test convivono**. Vitest per quasi tutte le librerie, Karma/Jasmine per pochi progetti residui, Jest per gli schematics, per `@spartacus/setup` e per gli stili SCSS. Lo script CI li tratta come tre gruppi distinti (`ci-scripts/unit-tests.sh:L5-L12`, `ci-scripts/unit-tests.sh:L88-L106`);
- **le utility di test** non sono pubblicate. Sono mock condivisi in `core-libs/storefront/shared/test/` e cartelle `testing/` dentro `core-libs/core/src/...`, raggiungibili con alias di path definiti solo per i test (`core-libs/storefront/vitest.config.ts:L14-L34`, `core-libs/storefront/tsconfig.spec.json:L16-L35`);
- **gli E2E SSR** (`projects/ssr-tests`) sono una suite Jest su Node. Avvia il server SSR dell'app demo come processo figlio e mette un proxy HTTP tra l'app e il backend OCC, così da poter iniettare errori e ritardi (`projects/ssr-tests/src/utils/ssr.utils.ts:L47-L61`, `projects/ssr-tests/src/utils/proxy.utils.ts:L58-L115`);
- **gli E2E browser** usano Cypress (`projects/storefrontapp-e2e-cypress`). Qui interessano solo struttura, convenzioni di nome e modo di lancio in CI (`ci-scripts/e2e-cypress.sh:L7-L15`);
- **le validazioni statiche** sono script bash con grep anti-`fdescribe`, ESLint con regole custom del workspace, stylelint con un plugin custom, prettier e i18n-lint (`ci-scripts/validate-lint.sh:L32-L109`);
- **i tool interni** sotto `tools/` sono i builder ng-packagr custom, la coerenza di dipendenze e tsconfig (`config:check`), la pipeline API Extractor per i dati delle migrazioni e un registry Verdaccio per provare gli schematics (`tools/build-lib/builders.json:L1-L14`, `tools/config/index.ts:L129-L136`, `tools/breaking-changes/package.json:L7-L27`, `tools/schematics/testing.ts:L92-L109`).

Il capitolo non insegna a scrivere test Angular in generale. Mostra **come questo repository decide cosa eseguire, con quale runner, con quali mock, e dove si rompe**. È utile a chi contribuisce a Spartacus e a chi, in un progetto cliente, vuole riusarne gli schemi (proxy SSR, cookie di config E2E, sharding pesato).

Capitoli collegati: l'engine SSR verificato dagli E2E SSR è in 39 — SSR ottimizzato e, per la parte Angular, in 07 — SSR, hydration e TransferState. L'app demo e il suo `server.ts` sono in 47 — L'app demo storefrontapp. I feature toggle, e quindi `provideMockFeatureToggles` e `MockFeatureDirective`, sono in 42 — Feature toggle e deprecazioni. Il mixin `forFeature`/`forVersion` testato con sass-true è in 38 — Stili e theming. Gli schematics, con i loro test `*_spec.ts` e i dati generati da `tools/breaking-changes`, sono in 43 — Schematics e migrazioni. Builder e schematics dal lato Angular sono in 08 — Schematics e builder.

> Convenzione dei file (dal dossier): `*.spec.ts` sono test Vitest, Karma o Jest unit; `*_spec.ts` sono test Jest degli schematics; `*.spec.scss` sono test sass-true; `*.cy.ts` sono spec Cypress.

2. Mappa dei file

PATH	RUOLO
`ci-scripts/unit-tests.sh`	dispatcher dei tre runner unit (`$TEST_RUNNER`, `$UNIT_TEST_GROUP_PROJECTS`, modalità affected)
`ci-scripts/compute-unit-shards.sh`	costruisce la matrice GitHub Actions degli shard (Karma/Jest/Vitest)
`ci-scripts/shard-lib.sh`	funzioni condivise: enumerazione progetti via `nx show projects`, peso per righe di spec, partizione LPT
`.github/actions/prepare-unit-shards/action.yml`	action composita che pubblica la matrice come output
`.github/workflows/ci-continuous-integration.yml`, `.github/workflows/ci-merge-checks.yml`, `.github/workflows/ci.yml`	workflow PR (`ci-continuous-integration.yml`: shard, unit, lint), merge check su PR pronta per la review (`ci-merge-checks.yml`: build ed e2e, con gating di `validate-e2e-execution.sh`), push/dispatch (`ci.yml`: pipeline completa, inclusi ssr-tests) (`.github/workflows/ci-merge-checks.yml:L1-L10`, `.github/workflows/ci.yml:L1-L9`)
`nx.json`	`targetDefaults` (cache, `dependsOn`), inferenza disattivata
`core-libs/core/project.json`, `core-libs/storefront/project.json`	target `build` (builder custom), `test-vitest`, `lint`
`feature-libs/cart/project.json`	modello feature lib: `test-vitest` + `test-jest` (schematics)
`integration-libs/opf/project.json`, `integration-libs/opf/karma.conf.js`, `integration-libs/opf/test.ts`	esempio di libreria rimasta su Karma/Jasmine
`core-libs/core/vitest.config.ts`	config Vitest di core: Analog plugin, jsdom, `forks`, coverage v8, junit
`core-libs/storefront/vitest.config.ts`	come sopra più alias ordinati per gli entry di test e i sorgenti core/storefront
`feature-libs/asm/vitest.config.ts`	esempio di config Vitest di feature lib (senza `restoreMocks`)
`testing/setup-vitest.ts`	setup Vitest condiviso: zone.js, compiler JIT, `initTestEnvironment` browser
`testing/patch-object-define-property.ts`	patch globale di `Object.defineProperty` per `spyOnProperty` (Karma)
`vitest-globals.d.ts`	riferimento ambient a `vitest/globals` per l'editor
`core-libs/core/src/test.ts`	entry Karma legacy di core (orfano: core non ha più target Karma)
`core-libs/core/tsconfig.spec.json`, `core-libs/storefront/tsconfig.spec.json`, `feature-libs/cart/tsconfig.spec.json`	types Vitest e `paths` degli entry di test
`core-libs/storefront/shared/test/*`	`MockFeatureDirective`, `MockFeatureLevelDirective`, `MockFeatureDirectivesModule`, `MockMediaComponent`, `MockWinRef`
`core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts`	`provideMockFeatureToggles` / `MockFeatureTogglesController`
`core-libs/setup/jest.config.js`, `core-libs/setup/setup-jest.ts`	Jest di `@spartacus/setup` con `ServerTestingModule`
`core-libs/styles/jest.schematics.config.js`, `core-libs/styles/test-jest.ts`, `core-libs/styles/test/scss.spec.js`	Jest che esegue i `.spec.scss` tramite sass-true

PATH	RUOLO
core-libs/styles/test/*.spec.scss, core-libs/styles/test/versioning-test-util.scss	test di forFeature, forVersion, compareVersion
core-libs/schematics/jest.schematics.config.js, feature-libs/cart/jest.schematics.config.js, jest-esm-matchers.js	Jest per gli schematics (*_spec.ts)
projects/ssr-tests/{project.json,package.json,jest.config.js,tsconfig.json,eslint.config.mjs,README.md}	progetto E2E SSR
projects/ssr-tests/validate-ssr-build.ts	globalSetup Jest: build prod, marker proxy, porta libera
projects/ssr-tests/src/environments/custom-test-environment.ts	environment Jest che allega i log SSR agli errori
projects/ssr-tests/src/utils/{ssr,proxy,http,log}.utils.ts	avvio/arresto server SSR, proxy backend su 9002, client HTTP, parsing .ssr.log
projects/ssr-tests/src/ssr-testing.spec.ts	scenari SSR (200, 404, 500, timeout backend, cache)
projects/storefrontapp-e2e-cypress/{package.json,cypress.config.ts,cypress.config.ci.ts}	script cy:* e config Cypress locale/CI
projects/storefrontapp-e2e-cypress/cypress/support/cx-config.commands.ts	comando cy.cxConfig() (stesso cookie degli E2E SSR)
ci-scripts/e2e-cypress.sh, ci-scripts/e2e-a11y-helpers.sh, ci-scripts/test-distribution.sh, ci-scripts/test-distribution.config.sh	esecuzione e distribuzione degli e2e Cypress
ci-scripts/validate-e2e-execution.sh	decide se servono gli e2e in base ai file cambiati
ci-scripts/validate-lint.sh	validazioni statiche (focus test, tsconfig prod, stylelint, ESLint, prettier, i18n)
ci-scripts/npm-commands.sh	wrapper bash degli script npm (build CI con nx run-many)
eslint.config.mjs, projects/storefrontapp/eslint.config.mjs, tools/eslint-rules/*	flat config ESLint, module boundaries, 11 regole custom
.stylelintrc.json, tools/stylelint-rules/*	stylelint e plugin valid-for-feature-mixin-argument
tools/build-lib/*	builder augmented-types e declaration-merging
tools/config/*	config:check / config:update (dipendenze, tsconfig paths, lock file, versione migrazione AI)
tools/breaking-changes/*	API Extractor → confronto API → dati per le migrazioni
tools/schematics/testing.ts	Verdaccio locale per provare gli schematics pubblicati

3. Come funziona passo per passo

3.1 Chi usa quale runner

Il criterio pratico è il **nome del target nx**:

TARGET NX	RUNNER	EXECUTOR	CHI LO HA
`test-vitest`	Vitest	`nx:run-commands` → `npx vitest run --config vitest.config.ts` nella root del progetto	`core`, `storefrontlib` e le feature/integration lib migrate (`core-libs/core/project.json:L20-L26`, `core-libs/storefront/project.json:L21-L27`, `feature-libs/cart/project.json:L20-L26`)
`test`	Karma/Jasmine	`@angular-devkit/build-angular:karma` con `main: test.ts` e `karma.conf.js` locale	`opf`, `epd-visualization`, `punchout`, `storefrontapp` (`integration-libs/opf/project.json:L20-L28`); anche `eslint-rules`, ma con executor `@nx/jest:jest` (`tools/eslint-rules/project.json:L7-L14`)
`test-jest`	Jest	`nx:run-commands` → `npm run test` o `npm run test:schematics`	schematics delle lib (`feature-libs/cart/project.json:L27-L32`), `setup` (`core-libs/setup/project.json:L20-L26`), `storefrontstyles` (`core-libs/styles/project.json:L6-L12`), `ssr-tests` (`projects/ssr-tests/project.json:L1-L22`)

I numeri allo SHA: 32 `vitest.config.ts` (2 core-libs, 20 feature-libs, 10 integration-libs) e 4 `karma.conf.js` (`projects/storefrontapp`, `integration-libs/epd-visualization`, `integration-libs/opf`, `integration-libs/punchout`). La fonte è un glob sul working tree riportato nel dossier (F13, es. `integration-libs/opf/karma.conf.js:L1-L49`, `core-libs/core/vitest.config.ts:L1-L61`). Le devDependencies root contengono tutte e tre le toolchain: `vitest ^4.1.10`, `@analogjs/vite-plugin-angular`, `@nx/vite`, `jsdom`, `karma ~6.4.4`, `jasmine-core ~6.3.0`, `jest ^30.2.0`, `jest-preset-angular ^17.0.0`, `sass-true ^10.0.0` (`package.json:L200-L293`).

Una feature lib migrata ha quindi **due** target di test: `test-vitest` per gli unit e `test-jest` per gli schematics (`feature-libs/cart/project.json:L20-L32`). `core` e `storefrontlib` invece hanno solo `test-vitest` (`core-libs/core/project.json:L7-L36`).

3.2 Configurazione Vitest

`core-libs/core/vitest.config.ts` è il modello:

1. **Plugin**: `angular()` di Analog compila componenti e decorator Angular per Vite; `nxViteTsPaths()` risolve gli alias dei tsconfig. La root è la cartella della lib (`core-libs/core/vitest.config.ts:L7-L13`).
2. **Esecuzione**: `pool: 'forks'`, `watch: false`, `globals: true` (`describe`/`it`/`vi` senza import), `restoreMocks: true`, `environment: 'jsdom'`, setup `../../testing/setup-vitest.ts`, include `**/*.spec.ts` (`core-libs/core/vitest.config.ts:L14-L21`).
3. **Typecheck** con il `tsconfig.spec.json` della lib (`core-libs/core/vitest.config.ts:L22-L24`). Quel tsconfig ha `strict: false`, `module: preserve`, `moduleResolution: bundler` e i types `vitest/globals`, `vitest/importMeta`, `vite/client`, `node`, `vitest` (`core-libs/core/tsconfig.spec.json:L1-L19`).
4. **Coverage** sempre attiva: provider `v8`, reporter `text-summary`/`html`/`lcov`, output in `coverage/core` (`core-libs/core/vitest.config.ts:L25-L30`). Esclude spec, `public_api.ts`, `index.ts`, `*.module.ts`, asset, `testing/` e `schematics/` (`core-libs/core/vitest.config.ts:L31-L43`). Le soglie sono 85/85/65/85, identiche in storefront (`core-libs/core/vitest.config.ts:L44-L49`, `core-libs/storefront/vitest.config.ts:L64-L69`).
5. **Reporter** `default` + `junit` in `unit-tests-reports/unit-test-core.xml`, letto dalla CI (`core-libs/core/vitest.config.ts:L51-L59`).

Il setup condiviso `testing/setup-vitest.ts` importa `zone.js`, `zone.js/testing` e `@angular/compiler`, poi chiama `getTestBed().initTestEnvironment(BrowserTestingModule, platformBrowserTesting())` **senza opzioni** (testing/setup-vitest.ts:L7-L19). Non c'è quindi il `ZoneChangeDetectionModule` che serve nei `test.ts` di Karma (§3.3).

`core-libs/storefront/vitest.config.ts` aggiunge `resolve.alias`. Mappa i sotto-path di test (`@spartacus/core/testing/feature-toggles`, `@spartacus/storefront/testing/mock-feature-directive`, `@spartacus/core/testing/i18n`, `@spartacus/core/testing/url-testing`) e poi `@spartacus/core`/`@spartacus/storefront` sui `public_api.ts` sorgente (core-libs/storefront/vitest.config.ts:L14-L34). Il commento avverte che l'ordine conta, perché Vite applica il primo alias che corrisponde e un alias "nudo" cattura anche i deep path (core-libs/storefront/vitest.config.ts:L16-L19). I test di storefront girano quindi contro i **sorgenti** di core, non contro `dist`; il `tsconfig.spec.json` di storefront infatti include `../../core-libs/core/src/**/*.ts` (core-libs/storefront/tsconfig.spec.json:L16-L35).

Le feature lib ripetono lo schema con alias propri. `asm`, ad esempio, mappa anche `core-libs/storefront/shared/test/mock-window-ref` e non ha `restoreMocks` (feature-libs/asm/vitest.config.ts:L10-L28). Per l'editor, un file ambient alla root referenzia `vitest/globals`, perché il `tsconfig.json` root non lo include nei `types` (vitest-globals.d.ts:L7-L14).

3.3 Karma/Jasmine residuo e il `test.ts` legacy

Una libreria Karma (es. `opf`) usa l'executor `@angular-devkit/build-angular:karma` con `main: integration-libs/opf/test.ts`, polyfill `zone.js`/`zone.js/testing` e `karma.conf.js` locale (integration-libs/opf/project.json:L20-L28). Il `karma.conf.js` usa jasmine e karma-coverage, scrive un junit in `unit-tests-reports/unit-test-opf.xml` e fissa le soglie a 80/80/70/80 (integration-libs/opf/karma.conf.js:L7-L36).

Il `test.ts` di `opf` registra un `ZoneChangeDetectionModule` con `provideZoneChangeDetection()` e inizializza TestBed con `teardown: { destroyAfterEach: false }` (integration-libs/opf/test.ts:L9-L32). Il `test.ts` di **core** fa lo stesso. Il motivo è spiegato nel commento: Angular 21 causa errori NG0100 con un `test.ts` custom. Lo stesso commento annota "No longer necessary under vitest" (core-libs/core/src/test.ts:L21-L30, core-libs/core/src/test.ts:L33-L39). In più, il `test.ts` di core importa `testing/patch-object-define-property` "just after zone.js imports" (core-libs/core/src/test.ts:L7-L12).

La patch sostituisce globalmente `Object.defineProperty`. Ogni proprietà con getter non configurabile diventa `configurable: true`, così `spyOnProperty` può sovrascrivere export di terze parti come `isDevMode` (testing/patch-object-define-property.ts:L7-L36). Serve "since `zone.js@0.11.4`" e non va importata in produzione (testing/patch-object-define-property.ts:L11-L24).

Allo SHA il `test.ts` di core è **orfano**. `core` non ha né target `test` né `karma.conf.js`, e il file resta citato solo nell'`exclude` di `tsconfig.lib.json` (core-libs/core/project.json:L7-L36, core-libs/core/tsconfig.lib.json:L24-L24).

3.4 Jest: `@spartacus/setup`, stili, schematics

`@spartacus/setup` (che contiene l'engine SSR) si testa con Jest. Il target `test-jest` esegue `npm run test`, cioè `jest --config ./jest.config.js` (core-libs/setup/project.json:L20-L26, core-libs/setup/package.json:L15-L17). Il config usa il preset `jest-preset-angular` e `setupFilesAfterEnv: ['<rootDir>/setup-jest.ts']` (core-libs/setup/jest.config.js:L7-L26). Il setup inizializza TestBed con `ServerTestingModule`/`platformServerTesting()`: l'ambiente è server, non browser (core-libs/setup/setup-jest.ts:L7-L19). Il config rimappa inoltre due dipendenze interne di Angular per problemi ESM/CJS. `beasties` va verso `node_modules/beasties`, `bundled-domino.mjs` verso un wrapper CJS in `__mocks__` (core-libs/setup/jest.config.js:L12-L25). La coverage è spenta di default (`collectCoverage: false`) e ha soglie 90/80/90/90 (core-libs/setup/jest.config.js:L36-L46).

Stili (`storefrontstyles`): l'unico target è `test-jest` → `jest --config ./jest.schematics.config.js` (core-libs/styles/project.json:L6-L12, core-libs/styles/package.json:L13-L15). Il config cerca solo `**/*.spec.js` e usa `test-jest.ts` come setup (core-libs/styles/jest.schematics.config.js:L4-L20), che è vuoto: "empty, for now" (core-libs/styles/test-jest.ts:L7-L7). L'unico `*.spec.js`, `scss.spec.js`, raccoglie con `globSync` tutti i `test/**/*.spec.scss` relativi a `process.cwd()`. Per ciascuno chiama `sassTrue.runSass({ describe, it }, file)`, più un test sentinella che fallisce se non trova file (core-libs/styles/test/scss.spec.js:L1-L15). Ogni `.spec.scss` importa sass-true e il modulo da testare e usa i mixin `describe`/`it`/`assert-equal`/`assert`/`output`/`expect` di sass-true (core-libs/styles/test/features.spec.scss:L1-L11):

- `features.spec.scss` verifica `getFeatureCssClass` (prefisso `cxFeat_`) e `forFeature`. Senza secondo argomento la classe va sull'antenato: `.cxFeat_<flag> .test` (core-libs/styles/test/features.spec.scss:L14-L35). Con `'currentSelector'` va sul selettore corrente: `.test.cxFeat_<flag>` (core-libs/styles/test/features.spec.scss:L121-L141);
- `versioning-test-util.scss` definisce quattro mixin helper (`shouldDisplayForRange`, `shouldNOTDisplayForRange`, `shouldDisplayForVersion`, `shouldNOTDisplayForVersion`) che avvolgono `it` + `assert` sul mixin `forVersion` (core-libs/styles/test/versioning-test-util.scss:L1-L72);
- i tre `versioning-forVersion-0N.spec.scss` fissano le globali `$_fullVersion`, `$_majorVersion`, `$styleVersion`, `$useLatestStyles` prima di chiamare gli helper. Il file 01 usa `3.2` (core-libs/styles/test/versioning-forVersion-01.spec.scss:L1-L22), lo 02 versioni a tre cifre `5.1.3` con `// prettier-ignore` (core-libs/styles/test/versioning-forVersion-02.spec.scss:L5-L19), lo 03 i confini dei range con `5.1` (core-libs/styles/test/versioning-forVersion-03.spec.scss:L5-L20);
- `versioning-functions.spec.scss` testa `compareVersion()` con ritorni 0/1/-1, anche con argomenti stringa (core-libs/styles/test/versioning-functions.spec.scss:L5-L47).

Schematics (`*_spec.ts`): i config Jest di core e delle feature lib usano `jest-preset-angular`, `testMatch: **/*_spec.ts`, `tsconfig.schematics.json` e un `transformIgnorePatterns` costruito da `jest-esm-matchers` (core-libs/schematics/jest.schematics.config.js:L1-L23). Quel file elenca i pacchetti solo-ESM che Jest deve trasformare, come `.mjs`, i locale Angular, `ora`, `chalk` (jest-esm-matchers.js:L7-L30). Le soglie sono 90/74/90/90 in core e 90/90/90/90 in cart (core-libs/schematics/jest.schematics.config.js:L28-L35, feature-libs/cart/jest.schematics.config.js:L28-L35). Lo script `test:schematics` di una feature lib pulisce gli output compilati di core-schematics e della lib prima di lanciare Jest (feature-libs/cart/package.json:L27-L27). Lo script root `test:all-schematics` li esegue tutti con `-u`, cioè aggiornando gli snapshot (package.json:L146-L146).

3.5 Utility di test condivise

Storefront (`core-libs/storefront/shared/test/`): il barrel esporta cinque mock (core-libs/storefront/shared/test/index.ts:L7-L11).

- `MockFeatureDirective` (`[cxFeature]`) renderizza il template solo se l'argomento **non** contiene `!`. Così i rami "deprecati" (`*cxFeature="'!toggle'"`) non compaiono nei test (core-libs/storefront/shared/test/mock-feature-directive.ts:L9-L22).
- `MockFeatureLevelDirective` (`[cxFeatureLevel]`) renderizza sempre (core-libs/storefront/shared/test/mock-feature-level-directive.ts:L9-L18).
- `MockFeatureDirectivesModule` importa, senza dichiararle, le due direttive standalone (core-libs/storefront/shared/test/mock-feature-directives.module.ts:L11-L14).
- `MockMediaComponent` (`cx-media`) rende un `<img>` solo se ricava una `src` da `container.product.url` o `container.url` (core-libs/storefront/shared/test/mock-media.component.ts:L9-L25).
- `MockWinRef` importa `vi` da `vitest`. Fornisce `localStorage`/`sessionStorage` fatti di `vi.fn()`, `location.href` vuoto e `isBrowser()` sempre `true` (core-libs/storefront/shared/test/mock-window-ref.ts:L7-L23).

Gli spec li importano in tre modi: con l'alias `@spartacus/storefront/testing/...`, con un path relativo, oppure con un path dalla root del repo (core-libs/storefront/cms-components/content/banner/banner.component.spec.ts:L23-L23, core-libs/storefront/cms-components/product/product-list/container/product-list.component.spec.ts:L33-L33, feature-libs/asm/root/services/asm-enabler.service.spec.ts:L12-L12). Alcune feature lib (`asm`, `cart`, `checkout`, `customer-ticketing`, `order`, `product`, `user`) dichiarano gli alias nei `compilerOptions.paths` del proprio `tsconfig.spec.json` (feature-libs/cart/tsconfig.spec.json:L35-L40); le altre feature lib con `tsconfig.spec.json` non hanno `paths`. `tools/config/manage-dependencies.ts` sa che questi file sono "da test". Classifica come uso in spec gli import provenienti da `test.ts`, `src/test.ts`, `setup-jest.ts`, `vitest.config.ts` e da qualunque file sotto `/shared/test/`, così le loro dipendenze non finiscono tra le dipendenze di produzione (tools/config/manage-dependencies.ts:L527-L538).

Core: le utility di test stanno nelle cartelle `testing/` dei moduli, escluse dalla coverage (core-libs/core/vitest.config.ts:L38-L38). L'esempio principale è `provideMockFeatureToggles(initial)` (core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L150-L158). Fa puntare `FeatureToggles`, `RootFeatureToggles`, `DefaultFeatureToggles` e il multi-provider `FeatureTogglesChunk` allo stesso `MockFeatureTogglesController`, creato nuovo a ogni setup di TestBed (core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L161-L184). Il meccanismo dei toggle è spiegato in 42.

3.6 Pattern ricorrenti negli spec

Un campione di sei spec, uno per tipo, mostra gli idiomi correnti:

- **Componente (Vitest)**: mock come classi locali, `TestBed.configureTestingModule` con `useClass`/`useValue`, `overrideComponent` per sostituire `MediaComponent`/`FeatureDirective` con i mock standalone, query con `By.css`/`By.directive` (core-libs/storefront/cms-components/content/banner/banner.component.spec.ts:L58-L74, core-libs/storefront/cms-components/content/banner/banner.component.spec.ts:L97-L129). Lo stato pilotato da un `BehaviorSubject` cambia in `beforeEach` annidati, prima di `fixture.detectChanges()` (core-libs/storefront/cms-components/content/banner/banner.component.spec.ts:L142-L155).
- **Facade NgRx (Vitest)**: store reale (`StoreModule.forRoot`, `EffectsModule.forRoot`, store module di feature), `vi.spyOn(store, 'dispatch')` e `provideMockFeatureToggles` (core-libs/core/src/site-context/facade/currency.service.spec.ts:L53-L72). Le asserzioni asincrone usano `await firstValueFrom(service.getAll())` dopo un dispatch di successo (core-libs/core/src/site-context/facade/currency.service.spec.ts:L101-L130).
- **Selettori (Vitest)**: `vi.mock('@ngrx/store', ...)` con `importOriginal`, per sostituire solo `select` (core-libs/core/src/product/store/selectors/product-reviews.selectors.spec.ts:L4-L7).
- **Adapter OCC (Vitest)**: `provideHttpClient(withInterceptorsFromDi()) + provideHttpClientTesting()`, `HttpTestingController.expectOne/flush` e `httpMock.verify()` in `afterEach` (core-libs/core/src/occ/adapters/product/occ-product-reviews.adapter.spec.ts:L29-L83). Le dipendenze reali come il `ConverterService` sono osservate con `vi.spyOn` senza cambiarne l'implementazione (core-libs/core/src/occ/adapters/product/occ-product-reviews.adapter.spec.ts:L56-L58).
- **Karma/Jasmine**: `jasmine.createSpyObj`, `.and.returnValue(...)`, callback `done` e `fail()` (integration-libs/opf/cta/core/services/opf-static-cta.service.spec.ts:L10-L79).
- **Schematics (Jest)**: `SchematicTestRunner.runExternalSchematic('@schematics/angular', ...)` per creare workspace e app, poi `add-spartacus` e `add-ssr` in `beforeAll`, infine `toMatchSnapshot()` sui file generati (core-libs/schematics/src/add-ssr/index_spec.ts:L17-L102).

Le istruzioni di progetto chiedono di preferire `firstValueFrom` alle subscription e di non condividere stato mutabile tra test (.claude/CLAUDE.md:L48-L50). Lo spec della facade segue la prima regola.

3.7 Unit test in CI: sharding pesato e dispatch

1. Il workflow PR calcola `affected` (vero per PR non `epic/*`) e invoca l'action `prepare-unit-shards` (`.github/workflows/ci-continuous-integration.yml:L51-L57`). L'action esegue `compute-unit-shards.sh` e pubblica `matrix` come output (`.github/actions/prepare-unit-shards/action.yml:L39-L51`). Il workflow di push `ci.yml` usa `affected: 'false'` (`.github/workflows/ci.yml:L64-L80`).
2. `compute-unit-shards.sh` fissa i default `KARMA_SHARDS=2`, `JEST_SHARDS=4`, `VITEST_SHARDS=4`, `AFFECTED=false` (`ci-scripts/compute-unit-shards.sh:L9-L12`).
3. Enumera i progetti **per target**. Karma = progetti con `test` meno app e solo-Jest; Jest = progetti con `test-jest` meno app; Vitest = tutti quelli con `test-vitest` (`ci-scripts/compute-unit-shards.sh:L19-L31`). L'enumerazione usa `nx show projects --with-target=<t> --json`, con `--affected` opzionale, e fallisce rumorosamente se nx fallisce (`ci-scripts/shard-lib.sh:L13-L28`).
4. Ogni progetto riceve un peso: il numero di righe "significative" dei suoi `*.spec.ts`, cioè escludendo import, commenti `//` e righe vuote, con minimo 1 (`ci-scripts/shard-lib.sh:L30-L48`).
5. `shard_partition` applica un greedy LPT (longest processing time): ordina per peso decrescente e assegna ogni progetto al bucket meno carico (`ci-scripts/shard-lib.sh:L56-L71`).
6. `matrix_legs` produce voci `{test-runner, shard-name: "<runner>-i/n", projects}` ed elimina i bucket vuoti (`ci-scripts/compute-unit-shards.sh:L34-L47`). In modalità run-all una matrice vuota è un errore (`ci-scripts/compute-unit-shards.sh:L57-L61`).
7. Ogni leg della matrice esegue `ci-scripts/unit-tests.sh` con `$TEST_RUNNER` e `$UNIT_TEST_GROUP_PROJECTS` impostati (`.github/workflows/ci-continuous-integration.yml:L59-L81`).
8. `unit-tests.sh`, con la variabile valorizzata, chiama `run_all_unit_tests` (`ci-scripts/unit-tests.sh:L108-L109`), che smista sul runner (`ci-scripts/unit-tests.sh:L88-L106`):
   - `karma` → `nx run-many --target=test ... -- --no-watch --source-map --code-coverage --browsers ChromeHeadless` (`ci-scripts/unit-tests.sh:L30-L42`);
   - `jest` → `nx run-many --target=test-jest ... -- --coverage --runInBand` (`ci-scripts/unit-tests.sh:L44-L56`);
   - `vitest` → `nx run-many --target=test-vitest ... -- --coverage` (`ci-scripts/unit-tests.sh:L58-L68`).
9. Il ramo Vitest arriva a `npx vitest run --config vitest.config.ts` nella cartella della lib (`core-libs/core/project.json:L20-L26`). Da lì valgono setup, jsdom, coverage e junit descritti in §3.2.

`shard-lib.sh` è condiviso anche con una pipeline Azure/piper tramite `split-unit-test-projects.sh`, che non è nel repo (`ci-scripts/shard-lib.sh:L3-L7`).

3.8 E2E SSR (`projects/ssr-tests`)

Il progetto nx `ssr-tests` (`projectType: library`) ha i target `lint` e `test-jest` (`npm run test --verbose`) (`projects/ssr-tests/project.json:L1-L22`). Lo script `test` del package esegue `jest --config ./jest.config.js`; le peerDependencies sono `http-proxy`, `jest-circus`, `jest-environment-node` (`projects/ssr-tests/package.json:L13-L24`). Il config trasforma con `ts-jest`, cerca `*.spec.ts`, usa un `testEnvironment` custom e un `globalSetup` (`projects/ssr-tests/jest.config.js:L9-L26`).

Sequenza completa:

1. **Build prerequisita**: `npm run build:libs && npm run build:ssr:local-http-backend` (`projects/ssr-tests/README.md:L7-L9`). L'env `local-http` imposta `CX_BASE_URL=http://localhost:9002`, cioè la porta del proxy di test (`package.json:L57-L57`, `.env-cmdrc:L11-L13`).
2. **Lancio**: `npm run test:ssr` / `test:ssr:ci` caricano l'env `dev`/`ci` con `env-cmd` e invocano `nx test ssr-tests` (`package.json:L156-L157`). Gli env `dev` e `ci` puntano `CX_BASE_URL` a backend remoti (`.env-cmdrc:L2-L4`, .

env-cmdrc:L14-L16), e lo spec usa quel valore come target del proxy (projects/ssr-tests/src/ssr-testing.spec.ts:L6-L6). La **build** punta dunque al proxy, mentre il **proxy** punta al backend reale.

3. globalSetup validateSsrBuild() controlla tre precondizioni dichiarate nella JSDoc: build prod, base OCC sul proxy locale, porta SSR libera (projects/ssr-tests/validate-ssr-build.ts:L7-L31). Lancia un errore se manca dist/storefrontapp/server/server.mjs, se nessun file di dist/storefrontapp/server contiene CX_BASE_URL:"http://localhost:9002", se un file server o browser contiene ngDevMode, o se la porta 4000 è occupata (projects/ssr-tests/validate-ssr-build.ts:L40-L58, projects/ssr-tests/validate-ssr-build.ts:L83-L141). Per la porta tenta un listen: EADDRINUSE significa occupata, qualunque altro errore conta come libera (projects/ssr-tests/validate-ssr-build.ts:L147-L165).
4. beforeEach → startSsrServer() svuota .ssr.log e lancia npm run serve:ssr della root in una shell detached. Passa SSR_CACHE, SSR_TIMEOUT, PORT e NODE_TLS_REJECT_UNAUTHORIZED=0, ridirige stdout e stderr nel log e attende il testo Node Express server listening on (projects/ssr-tests/src/utils/ssr.utils.ts:L47-L61). serve:ssr è NG_ALLOWED_HOSTS=localhost node dist/storefrontapp/server/server.mjs (package.json:L152-L152). Il server.ts demo legge SSR_TIMEOUT e SSR_CACHE per le SsrOptimizationOptions e stampa il messaggio atteso (projects/storefrontapp/src/server.ts:L22-L27, projects/storefrontapp/src/server.ts:L93-L93).
5. **Nel test** → startBackendProxyServer({ target, responseInterceptor? }) crea un http-proxy con secure: false e selfHandleResponse solo se c'è un interceptor, e ascolta sempre sulla porta 9002 (projects/ssr-tests/src/utils/proxy.utils.ts:L58-L115). Riscrive l'header host con il target (projects/ssr-tests/src/utils/proxy.utils.ts:L75-L77). Con interceptor bufferizza il body, lo decomprime (gzip/deflate) e lo passa all'interceptor, che deve chiamare res.end (projects/ssr-tests/src/utils/proxy.utils.ts:L79-L105, projects/ssr-tests/src/utils/proxy.utils.ts:L118-L127).
6. **Richiesta** → sendRequestToSsrServer({ path, testConfig? }) fa una GET su localhost:4000 con un header Cookie costruito da testConfig (projects/ssr-tests/src/utils/http.utils.ts:L13-L16, projects/ssr-tests/src/utils/http.utils.ts:L42-L54). Il cookie si chiama cxConfigE2E e contiene JSON URI-encoded; lo legge il TestConfigModule dell'app demo (projects/ssr-tests/src/utils/http.utils.ts:L75-L89, projects/storefrontapp/src/app/private/private.providers.ts:L54-L54). In questo modo un'app buildata una volta sola si può testare con varianti di config iniettate a runtime (projects/ssr-tests/src/utils/http.utils.ts:L27-L37).
7. **Asserzioni** su status code e messaggi di log. getLogsObjects legge ./.ssr.log e scarta le righe non JSON, getLogsMessages estrae message (projects/ssr-tests/src/utils/log.utils.ts:L18-L18, projects/ssr-tests/src/utils/log.utils.ts:L59-L80).
8. **Su fallimento**, CustomTestEnvironment (che estende jest-environment-node) intercetta test_done e allega i log SSR pretty-printed come cause sia dell'errore originale sia di quello asincrono, ad esempio un timeout (projects/ssr-tests/src/environments/custom-test-environment.ts:L11-L43). Usa cause perché è l'unica proprietà, oltre a message, che Jest stampa (projects/ssr-tests/src/environments/custom-test-environment.ts:L26-L29).
9. afterEach: backendProxy.close() e killSsrServer(), che invia il segnale al process group (-child.pid) e risolve all'exit (projects/ssr-tests/src/ssr-testing.spec.ts:L14-L17, projects/ssr-tests/src/utils/ssr.utils.ts:L67-L74).

Gli scenari verificati sono questi (projects/ssr-tests/src/ssr-testing.spec.ts:L26-L82):

- 200, con i log "Rendering started" e "Request is waiting...";
- 404 su pagina inesistente;
- 404 se cms/pages risponde 404;
- 500 se fallisce un'altra API (cms/components);
- 500 se /languages è ritardata oltre un backend.timeout.server di 4000 ms iniettato via testConfig. Il test verifica anche il log "exceeded expected time of 4000ms and was aborted" (projects/ssr-tests/src/

ssr-testing.spec.ts:L92-L129);

- con cache attiva, la seconda richiesta deve loggare `Render from cache (...)`. Se però il primo render è fallito con 404, la seconda **non** deve venire dalla cache (projects/ssr-tests/src/ssr-testing.spec.ts:L133-L196).

Il timeout Jest è `DEFAULT_SSR_TIMEOUT` (20000 ms) e raddoppia nei test che chiamano il server due volte (projects/ssr-tests/src/ssr-testing.spec.ts:L6-L12, projects/ssr-tests/src/ssr-testing.spec.ts:L164-L165). La pagina usata è `/contact`, "less busy" della home (projects/ssr-tests/src/ssr-testing.spec.ts:L12-L12). Il comportamento dell'engine sotto test (fallback CSR, cache, timeout) è descritto in 39.

3.9 E2E Cypress (struttura)

`cypress/e2e` contiene `a11y` (b2b, b2c, helpers), `b2b` (regression, vendor), `regression` (per dominio), `ssr` (2 spec) e `vendor` (per integrazione) (projects/storefrontapp-e2e-cypress/cypress/e2e/, listing nel dossier F165). Le convenzioni di nome separano `*.core-e2e.cy.ts` (sottoinsieme core), `*.e2e.cy.ts`, `*.e2e-flaky.cy.ts` e `*.a11y-e2e.cy.ts` (projects/storefrontapp-e2e-cypress/package.json:L18-L19, projects/storefrontapp-e2e-cypress/package.json:L61-L61). Gli script root `e2e:*` delegano ai `cy:*` del package con `npm --prefix` (package.json:L65-L124).

- `cypress.config.ts` (locale): baseUrl `http://localhost:4200`, `retries` 2 sia in run sia in open, env `BASE_SITE: 'electronics-spa'`, `OCC_PREFIX: '/occ/v2'` e `CLIENT_ID` derivato da `JDK_VERSION` (projects/storefrontapp-e2e-cypress/cypress.config.ts:L9-L47).
- `cypress.config.ci.ts`: aggiunge `projectId`, `video: true`, esclude `**/*.example-e2e.cy.ts` e abilita gli screenshot solo con `CYPRESS_ENABLE_SCREENSHOTS=true` (projects/storefrontapp-e2e-cypress/cypress.config.ci.ts:L18-L49).
- `cy:run:ci` registra sulla Cypress Dashboard con `--record --parallel --ci-build-id $BUILD_NUMBER --group B2C`, escludendo vendor/b2b/ssr, a11y e my-account-v2 (projects/storefrontapp-e2e-cypress/package.json:L24-L24).
- Il comando custom `cy.cxConfig(config)` imposta lo **stesso** cookie `cxConfigE2E` degli E2E SSR (projects/storefrontapp-e2e-cypress/cypress/support/cx-config.commands.ts:L26-L28).

In CI, `ci-scripts/e2e-cypress.sh` accetta `--suite/-s`, `--environment`, `--ssr`, `--skip-build` (ci-scripts/e2e-cypress.sh:L7-L15). Senza `--skip-build` esegue `npm ci` e `build_libs_ci`, fallisce se il log contiene `Warning: Can't resolve all parameters for`, poi esegue `build:csr` (ci-scripts/e2e-cypress.sh:L86-L112). In modalità SSR serve l'app con `serve:ssr:ci` e sceglie `e2e:run:ci:core:ssr` (PR non epic, commit di bot) oppure `e2e:run:ci:ssr` (ci-scripts/e2e-cypress.sh:L114-L166). In modalità CSR serve con `start:pwa` (http-server su 4200) e chiama `run_tests_for_suite` con scope `core` o `full` (ci-scripts/e2e-cypress.sh:L167-L197, package.json:L143-L143). Per `:a11y` carica `e2e-a11y-helpers.sh`; negli altri casi compone il nome dello script `e2e:run:ci[:core]<suite>` (ci-scripts/e2e-cypress.sh:L17-L30).

La distribuzione a11y senza recording è round-robin: file in ordine alfabetico, il file `i` va al container `(i % total) + 1` (ci-scripts/test-distribution.sh:L4-L26, ci-scripts/test-distribution.sh:L30-L75). Con `ENABLE_A11Y_RECORDING=true` si usano invece gli script `:record` della Dashboard; altrimenti si esporta `CYPRESS_SPEC_OVERRIDE` (ci-scripts/e2e-a11y-helpers.sh:L74-L125).

`validate-e2e-execution.sh` imposta `RUN_E2E=true` se il diff verso la base contiene file diversi da `*.md`, `docs/**`, `tools/**`, `*.spec.ts`, `**/schematics/**` (ci-scripts/validate-e2e-execution.sh:L5-L20, .github/workflows/ci.yml:L59-L63).

3.10 Lint e validazioni statiche

`validate-lint.sh` (job `linting`, con `LINT_PARALLEL=4` nel workflow PR: `.github/workflows/ci-continuous-integration.yml:L119-L124`) esegue in ordine:

1. verifica che `projects/storefrontapp/tsconfig.app.prod.json` **non** contenga `core-libs/storefront/public_api`, perché la build prod deve usare `dist` (`ci-scripts/validate-lint.sh:L11-L30`);
2. fallisce se trova `fdescribe(`, `describe.only(`, `fit(` o `it.only(` in un `*spec.ts` di `projects`, `feature-libs`, `integration-libs`, `core-libs` (`ci-scripts/validate-lint.sh:L32-L70`);
3. fallisce se storefrontlib importa se stessa (`from 'storefrontlib'`) (`ci-scripts/validate-lint.sh:L72-L80`);
4. stylelint → ESLint via nx (`affected` se `LINT_AFFECTED=true`, altrimenti `run-many --all`; `$LINT_PARALLEL` default 3; heap 3584 MB) → prettier → i18n-lint (`ci-scripts/validate-lint.sh:L82-L109`).

Gli script root corrispondenti sono `lint`, `lint:styles`, `prettier` (`--list-different`) e `i18n-lint`, che controlla gli attributi `alt,title,placeholder,aria-label` negli HTML (`package.json:L128-L131`).

ESLint. Il target `lint` di ogni lib usa `@angular-eslint/builder:lint` su `**/*.ts` e `**/*.html` (`core-libs/core/project.json:L27-L35`). La flat config root:

- ignora `dist`, `out-tsc`, l'intero progetto Cypress e i `vitest.config.ts` (`eslint.config.mjs:L18-L27`);
- impone selettori con prefisso `cx` e `prefer-standalone` come errore (`eslint.config.mjs:L51-L78`);
- applica `@nx/enforce-module-boundaries` sui tag (`eslint.config.mjs:L10-L16`, `eslint.config.mjs:L129-L154`). Nessuno dipende da `type:app`; `type:feature` non dipende da `type:integration`; `type:ui` non da `type:feature`; `scope:core` non da `type:ui`/`type:feature`. `core` ha i tag `type:util` + `scope:core`, `storefrontlib` ha `type:ui` (`core-libs/core/project.json:L37-L37`, `core-libs/storefront/project.json:L38-L38`);
- con una regola `no-restricted-syntax` (warn) segnala gli `inject()` assegnati a campi `private`, che devono essere `protected` per l'estendibilità, salvo `FeatureConfigService`/`FeatureToggles` (`eslint.config.mjs:L179-L192`);
- attiva le regole del workspace (`@nx/workspace-*`) per glob di file. Le `use-provide-default-*` valgono solo sui `*.module.ts`, quelle NgRx sui `*.action*.ts`, le altre su tutti i `.ts` (`eslint.config.mjs:L231-L258`).

Le 11 regole custom sono registrate in `tools/eslint-rules/index.ts` (`tools/eslint-rules/index.ts:L76-L101`). Sono scritte con `ESLintUtils.RuleCreator`; ad esempio `no-const-enum` esiste perché `const enum` non è compatibile con `isolatedModules: true` (`tools/eslint-rules/rules/no-const-enum.ts:L9-L37`). Si testano con `RuleTester` di `@angular-eslint/test-utils` (`tools/eslint-rules/rules/no-const-enum.spec.ts:L1-L20`) dentro un progetto nx con target `test` ed executor `@nx/jest:jest` (`tools/eslint-rules/project.json:L7-L14`, `tools/eslint-rules/jest.config.ts:L8-L16`). La regola `no-storefrontapp-false-feature-toggles` è attiva solo nell'app demo (`projects/storefrontapp/eslint.config.mjs:L28-L28`).

Stylelint estende `stylelint-config-recommended-scss`, carica il plugin `./tools/stylelint-rules` con la regola `spartacus/valid-for-feature-mixin-argument` e vieta le proprietà fisiche left/right (`margin-left`, `padding-right`, `border-left`, …) e alcune shorthand logiche (`padding-inline`, `margin-block`, `border-inline`, …), oltre a `text-align: left|right` (`.stylelintrc.json:L1-L5`, `.stylelintrc.json:L22-L44`, `tools/stylelint-rules/index.js:L9-L11`).

3.11 Nx, build e tool di configurazione

- `nx.json`: `targetDefaults` con cache su `build`, `lint`, `test`, `e2e`; `build.dependsOn: ["^build"]`; `useInferencePlugins: false` e `analytics: false` (`nx.json:L1-L23`). DA VERIFICARE l'effetto di `useInferencePlugins: false` sui target ricavati dagli script npm: gli script CI escludono esplicitamente dal

target `test` progetti che hanno uno script npm `test` ma nessun target `test` nel `project.json` (ci-scripts/compute-unit-shards.sh:L19-L25, ci-scripts/unit-tests.sh:L5-L6), il che fa pensare che Nx li esponga comunque come target.

- **Build delle lib**: `core` e `storefrontlib` usano il builder custom `./tools/build-lib:declaration-merging`, `setup` usa `@angular-devkit/build-angular:ng-packagr` (core-libs/core/project.json:L8-L19, core-libs/setup/project.json:L8-L19). `tools/build-lib` registra `augmented-types`, che propaga gli export di tipi al `.d.ts` principale per la module augmentation, e `declaration-merging`, che corregge i path relativi nel `.d.ts` flattened (tools/build-lib/builders.json:L1-L14).
- `build:libs` valida i JSON di traduzione e poi builda in ordine core → storefrontlib → schematics/user → cart → … → setup → s4-service, con gruppi `concurrently --kill-others-on-fail` (package.json:L35-L35). In CI, `build_libs_ci` compila in parallelo gli schematics delle lib che hanno `build:schematics`. Poi lancia `nx run-many --target=build --configuration=production --parallel=N`, escludendo app e Cypress e sfruttando grafo e cache di nx (ci-scripts/npm-commands.sh:L14-L43). `npm-commands.sh` centralizza i wrapper bash degli script npm (`build_ssr_local_http`, `test_ssr`, …), così rinominare uno script npm non richiede di toccare più punti (ci-scripts/npm-commands.sh:L5-L7, ci-scripts/npm-commands.sh:L45-L60).
- `config:check` / `config:update` eseguono `tools/config/index.ts`, il secondo con `--fix`; `generate:deps` esegue `tools/schematics/dependency-collector.ts` (package.json:L62-L64). Il CLI accetta `--fix`, `--bump-versions`, `--generate-deps` (tools/config/index.ts:L129-L136). Il modello del repository nasce dai `package.json` in `{core-libs,feature-libs,integration-libs,projects}/*`, esclusi app demo e Cypress (tools/config/index.ts:L228-L263). La sequenza è: lock file (fail-fast), dipendenze, tsconfig paths, versione della migrazione AI, `generate:deps` (con `--compare` in modalità check); in fix aggiunge `npm install` e `prettier:fix`; se ci sono errori imposta `process.exitCode = 1` (tools/config/index.ts:L330-L371). `syncAiMigrationVersion` allinea la versione di `add-or-update-ai-skills` in `migrations.json` a quella di `@spartacus/schematics` (tools/config/index.ts:L280-L325). `tsconfig-paths.ts` gestisce i `compilerOptions.paths` di tutti i tsconfig secondo un elenco di assunzioni dichiarate, ad esempio "all dependencies to other spartacus libs are peerDependencies" (tools/config/tsconfig-paths.ts:L7-L21).
- **API Extractor** (`tools/breaking-changes`) è un pacchetto a sé con la pipeline `extract-*` → `parse-*` → `compare` → `gen-*` → `regenerate` (tools/breaking-changes/package.json:L7-L27). `extract.ts` trova tutti i `dist/**/public_api.d.ts` del clone e lancia API Extractor su ognuno (tools/breaking-changes/extract.ts:L29-L44). La versione target sta in `common.ts` (`NEW_VERSION`) e determina anche la cartella delle migrazioni schematics in cui finiscono i dati (tools/breaking-changes/common.ts:L12-L18). I generatori `gen-const`, `gen-deleted`, `gen-moved`, `gen-methods-props` producono i dati per gli schematics di migrazione (tools/breaking-changes/readme.md:L57-L66); vedi 43.
- **Verdaccio**: `tools/schematics/testing.ts` avvia un registry locale su `http://localhost:4873/`, punta `@spartacus:registry` lì e pubblica i pacchetti per provare gli schematics a mano (tools/schematics/testing.ts:L92-L109, tools/schematics/testing.ts:L150-L156).

3.12 Pipeline CI completa

In `ci.yml` (push su `develop`, `develop-*`, `release/*` e dispatch manuale: .github/workflows/ci.yml:L1-L8) i job sono, in ordine (.github/workflows/ci.yml:L28-L358):

- `detect_changes`, `no_retries`, `validate_e2e_execution`;
- `prepare_unit_shards`, `unit_tests`, `linting`;
- `build_libs`, `build_apps` (matrice B2C CSR, B2B CSR, B2C SSR);
- `b2c_e2e_tests` (5 container), `b2c_ssr_e2e_tests`, `b2b_e2e_tests` (4), `a11y_e2e_tests` (3), `ssr_tests`;
- `build_conclusion`, `send_slack_message`.

`build_libs` usa l'action `build-integrity-check` (fasi `snapshot`/`verify`) per verificare che la build non modifichi i sorgenti, e mette in cache `dist` (`.github/workflows/ci.yml:L132-L161`). `ssr_tests` ripristina le lib buildate, builda con `build_ssr_local_http` e lancia `test_ssr` (`.github/workflows/ci.yml:L299-L322`). Gli e2e partono con `e2e-cypress.sh --skip-build`, a cui si aggiunge `--ssr`, `-s b2b` o `-s a11y` (`.github/workflows/ci.yml:L232-L298`).

---

4. Diagrammi

4.1 Unit test in CI: dalla matrice al runner

■ **TAVOLA 44.1** diagramma a tutta pagina, in fondo al capitolo

Riferimenti dei nodi: `.github/workflows/ci-continuous-integration.yml:L51-L81`, `.github/actions/prepare-unit-shards/action.yml:L39-L51`, `ci-scripts/compute-unit-shards.sh:L19-L55`, `ci-scripts/shard-lib.sh:L13-L71`, `ci-scripts/unit-tests.sh:L30-L68`, `ci-scripts/unit-tests.sh:L88-L106`, `core-libs/core/project.json:L20-L26`, `core-libs/core/vitest.config.ts:L14-L59`.

4.2 Un test E2E SSR con proxy e interceptor

■ **TAVOLA 44.2** diagramma a tutta pagina, in fondo al capitolo

Riferimenti: `projects/ssr-tests/validate-ssr-build.ts:L83-L141`, `projects/ssr-tests/src/utils/ssr.utils.ts:L47-L74`, `projects/ssr-tests/src/utils/log.utils.ts:L82-L99`, `projects/ssr-tests/src/utils/proxy.utils.ts:L58-L127`, `projects/ssr-tests/src/utils/http.utils.ts:L42-L89`, `projects/ssr-tests/src/environments/custom-test-environment.ts:L19-L43`, `projects/ssr-tests/src/ssr-testing.spec.ts:L14-L82`, `.env-cmdrc:L2-L16`.

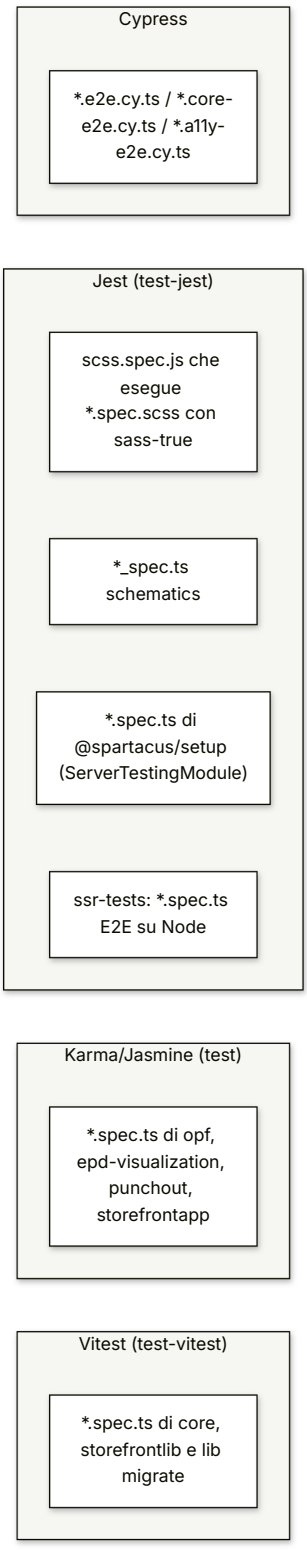
4.4 Mappa dei runner per tipo di file



Riferimenti: core-libs/core/project.json:L20-L26, integration-libs/opf/project.json:L20-L28, core-libs/schematics/jest.schematics.config.js:L1-L23, core-libs/setup/setup-jest.ts:L7-L19, core-libs/styles/test/scss.spec.js:L1-L15, projects/ssr-tests/jest.config.js:L9-L26, projects/storefrontapp-e2e-cypress/package.json:L18-L24.

5. Estratti di codice reale

5.1 Dispatch del runner — ci-scripts/unit-tests.sh:L88-L118

BASH

```bash
function run_all_unit_tests {
    case "$TEST_RUNNER" in
        karma)
            run_karma_group_tests
            ;;
        jest)
            run_jest_group_tests
            ;;
        vitest)
            run_vitest_group_tests
            ;;
        *)
            run_karma_group_tests
            run_jest_group_tests
            run_vitest_group_tests
            ;;
    esac
    return 0
}

if [[ -n "${UNIT_TEST_GROUP_PROJECTS:-}" ]]; then
    run_all_unit_tests
elif [[ "${GITHUB_EVENT_NAME}" == "pull_request" ]]; then
    if [[ "${GITHUB_HEAD_REF}" == epic/* ]]; then
        run_all_unit_tests
    else
        run_affected_unit_tests
    fi
else
    run_all_unit_tests
fi
```

5.2 Partizione LPT — ci-scripts/shard-lib.sh:L56-L71

BASH

```bash
# Greedy longest-processing-time partition of a weighted list into N buckets.
# $1 = JSON array of {name,weight}, $2 = number of buckets.
# Emits a JSON array of buckets, each a JSON array of project names (sorted).
shard_partition() {
    local weighted="$1" n="$2"
    jq -nc --argjson list "$weighted" --argjson n "$n" '
        ($list | sort_by(-.weight)) as $sorted
        | reduce $sorted[] as $p ({buckets: [range(0;$n) | {items:[], load:0}]};
```

```
            (.buckets | to_entries | min_by(.value.load).key) as $idx
            | .buckets[$idx].items += [$p.name]
            | .buckets[$idx].load  += $p.weight
          )
        | .buckets | map(.items | sort)
    '
    return 0
}
```

5.3 Peso di un progetto — `ci-scripts/shard-lib.sh:L41-L48`

BASH

```
        if [[ -n "$root" && -d "$root" ]]; then
            # Count only "meaningful" spec lines: skip imports, comment-only and blank lines,
            # so the weight better reflects test volume than raw line count.
            weight=$(find "$root" -name '*.spec.ts' -exec cat {} + 2>/dev/null | grep -cvE '^\s*
(import|//|$)' | tr -d ' ')
        else
            weight=1
        fi
        [[ -z "$weight" || "$weight" -eq 0 ]] && weight=1
```

5.4 Config Vitest di core — `core-libs/core/vitest.config.ts:L11-L30`

TS

```
export default defineConfig({
  root: import.meta.dirname,
  plugins: [angular(), nxViteTsPaths()],
  test: {
    pool: 'forks',
    watch: false,
    globals: true,
    restoreMocks: true,
    environment: 'jsdom',
    setupFiles: ['../../testing/setup-vitest.ts'],
    include: ['**/*.spec.ts'],
    typecheck: {
      tsconfig: `${import.meta.dirname}/tsconfig.spec.json`,
    },
    coverage: {
      enabled: true,
      provider: 'v8',
      reporter: ['text-summary', 'html', 'lcov'],
      reportsDirectory: `${import.meta.dirname}/../../coverage/core`,
      include: ['**/*.ts'],
```

5.5 Setup Vitest condiviso — testing/setup-vitest.ts:L7-L19

```ts
import 'zone.js';
import 'zone.js/testing';
import '@angular/compiler';
import { getTestBed } from '@angular/core/testing';
import {
  BrowserTestingModule,
  platformBrowserTesting,
} from '@angular/platform-browser/testing';

getTestBed().initTestEnvironment(
  BrowserTestingModule,
  platformBrowserTesting()
);
```

5.6 Alias ordinati — core-libs/storefront/vitest.config.ts:L14-L34

```ts
  resolve: {
    alias: {
      // NOTE: order matters. Vite matches string aliases in order (first match
      // wins), and a bare alias like '@spartacus/storefront' also matches any
      // '@spartacus/storefront/...' import. The specific deep-path aliases must
      // come BEFORE the general package aliases, otherwise they get shadowed.
      '@spartacus/core/testing/feature-toggles': `${import.meta.dirname}/../../core-
libs/core/src/features-config/feature-toggles/testing/index.ts`,
      '@spartacus/storefront/testing/mock-feature-directive': `${import.meta.dirname}/../../core-
libs/storefront/shared/test/mock-feature-directive.ts`,
      // ...
      '@spartacus/core': path.resolve(
        import.meta.dirname,
        '../core/public_api.ts'
      ),
      '@spartacus/storefront': path.resolve(
        import.meta.dirname,
        './public_api.ts'
      ),
    },
  },
```

5.7 test.ts legacy Karma di core — core-libs/core/src/test.ts:L21-L39

```ts
// Angular 21 introduced a change that causes NG0100 errors in Karma tests.
// See: https://github.com/angular/angular-cli/issues/32047
// Angular fixed this for built-in test.ts: https://github.com/angular/angular-cli/pull/32049
// Since we use a custom test.ts, we must manually provide zone change detection.
```

```
//No longer necessary under vitest
@NgModule({
  providers: [provideZoneChangeDetection()],
})
class ZoneChangeDetectionModule {}

// First, initialize the Angular testing environment.
getTestBed().initTestEnvironment(
  [BrowserTestingModule, ZoneChangeDetectionModule],
  platformBrowserTesting(),
  {
    teardown: { destroyAfterEach: false },
  }
);
```

5.8 Patch di `Object.defineProperty` — testing/patch-object-define-property.ts:L27-L36

TS

```
const { defineProperty } = Object;
Object.defineProperty = (object, name, meta) => {
  if (meta.get && !meta.configurable) {
    return defineProperty(object, name, {
      ...meta,
      configurable: true,
    });
  }
  return defineProperty(object, name, meta);
};
```

5.9 Mock di `*cxFeature` — core-libs/storefront/shared/test/mock-feature-directive.ts:L9-L23

TS

```
@Directive({ selector: '[cxFeature]' })
export class MockFeatureDirective {
  constructor(
    protected templateRef: TemplateRef<any>,
    protected viewContainer: ViewContainerRef
  ) {}

  @Input() set cxFeature(_feature: string) {
    // ensure the deprecated DOM changes are not rendered during tests

    if (!_feature.toString().includes('!')) {
      this.viewContainer.createEmbeddedView(this.templateRef);
    }
  }
}
```

5.10 provideMockFeatureToggles — core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L150-L166

```ts
export function provideMockFeatureToggles(
  initial: Partial<FeatureTogglesInterface> = {}
): Provider[] {
  return [
    // The controller is created fresh by the injector on each TestBed setup,
    // so mutations via .set() from one test cannot leak into the next.
    {
      provide: MockFeatureTogglesController,
      useFactory: () => createController(initial),
    },

    // New, preferred path: `inject(FeatureToggles)`.
    {
      provide: FeatureToggles,
      useFactory: (c: MockFeatureTogglesController) => c,
      deps: [MockFeatureTogglesController],
    },
```

5.11 Runner sass-true — core-libs/styles/test/scss.spec.js:L1-L15

```js
const path = require('path');
const sassTrue = require('sass-true');
const { globSync } = require('glob');

const testFiles = globSync(path.resolve(process.cwd(), `test/**/*.spec.scss`));

describe('Scss Styles test runner', () => {
  it('should discover scss spec files to run through sass-true', () => {
    expect(testFiles.length).toBeGreaterThan(0);
  });
});

describe('Scss Styles', () => {
  testFiles.forEach((file) => sassTrue.runSass({ describe, it }, file));
});
```

5.12 Un test SCSS — core-libs/styles/test/features.spec.scss:L14-L35

```scss
  @include describe('forFeature') {
    @include it('should prepend the feature class to the ancestor selector') {
      @include assert {
        @include output(false) {
          .test {
            color: yellow;
```

```
            @include forFeature('someFeatureFlag') {
              color: green;
            }
          }
        }
        @include expect(false) {
          .test {
            color: yellow;
          }
          .cxFeat_someFeatureFlag .test {
            color: green;
          }
        }
      }
    }
```

5.13 Avvio del server SSR — `projects/ssr-tests/src/utils/ssr.utils.ts:L47-L74`

TS

```ts
export async function startSsrServer({
  port = 4000,
  cache = false,
  timeout = DEFAULT_SSR_TIMEOUT,
}: SsrServerOptions = {}) {
  LogUtils.clearSsrLogFile();

  child = childProcess.spawn(
    // `2>&1` - redirect stderr to stdout, so also `console.error` and `console.warn` messages are captured in the log file
    `NODE_TLS_REJECT_UNAUTHORIZED=0 SSR_CACHE=${cache} SSR_TIMEOUT=${timeout} PORT=${port} npm run serve:ssr --prefix ../../> .ssr.log 2>&1`,
    { detached: true, shell: true }
  );

  await LogUtils.waitUntilLogContainsText(`Node Express server listening on `);
}

// ...
export function killSsrServer() {
  return new Promise((resolve) => {
    process.kill(-child.pid);
    child.on('exit', () => {
      resolve(true);
    });
  });
}
```

5.14 Proxy con interceptor — projects/ssr-tests/src/utils/proxy.utils.ts:L58-L115

TS

```ts
export async function startBackendProxyServer(
  options: ProxyOptions
): Promise<http.Server> {
  const proxyOptions: httpProxy.ServerOptions = {
    secure: false,
    selfHandleResponse: !!options.responseInterceptor,
  };
  // ...
  const proxy = httpProxy.createProxyServer(proxyOptions);

  proxy.on('proxyReq', (proxyReq) => {
    proxyReq.setHeader('host', extractUrlWithoutProtocol(options.target));
  });

  if (options.responseInterceptor) {
    proxy.on('proxyRes', (proxyRes, req, res) => {
      // We have to buffer the response body before passing it to the interceptor
      const bodyBuffer: Buffer[] = [];
      proxyRes.on('data', (chunk) => {
        bodyBuffer.push(chunk);
      });
      proxyRes.on('end', () => {
        const body = unzipResponseBody(
          Buffer.concat(bodyBuffer),
          proxyRes.headers['content-encoding']
        );
        // ...
      });
    });
  }

  return new Promise((resolve) => {
    const server = http.createServer((req, res) => {
      proxy.web(req, res, { target: options.target });
    });

    server.listen(9002, () => {
      resolve(server);
    });
  });
}
```

5.15 Cookie di config E2E — projects/ssr-tests/src/utils/http.utils.ts:L75-L89

```ts
/**
 * Builds a cookie string with key 'cxConfigE2E' and the given `cxConfig`
 * object as a value that is stringified and URI-encoded.
 *
 * Note: `TestConfigModule` of Spartacus will read this cookie
 *       and inject the passed config chunk into Spartacus global config.
 */
function buildCxConfigE2ECookie(cxConfig?: object): string {
  if (!cxConfig) {
    return '{}';
  }
  const cookieKey = 'cxConfigE2E';
  const cookieValue = encodeURIComponent(JSON.stringify(cxConfig));
  return `${cookieKey}=${cookieValue}`;
}
```

5.16 Scenario timeout backend — projects/ssr-tests/src/ssr-testing.spec.ts:L98-L128

```ts
          const BACKEND_TIMEOUT_TIME_LIMIT = 4000;
          const API_DELAY = BACKEND_TIMEOUT_TIME_LIMIT + 1;

          backendProxy = await ProxyUtils.startBackendProxyServer({
            target: BACKEND_BASE_URL,
            responseInterceptor: ({ res, req, body }) => {
              // Delay the response from Backend API, but only for for the /languages endpoint.
              // We want Spartacus to consider this Backend API request as Timeouted (therefore failed).
              if (req.url?.includes('languages')) {
                setTimeout(() => res.end(body), API_DELAY);
              } else {
                res.end(body);
              }
            },
          });

          const response = await HttpUtils.sendRequestToSsrServer({
            path: REQUEST_PATH,
            testConfig: {
              backend: { timeout: { server: BACKEND_TIMEOUT_TIME_LIMIT } },
            },
          });

          expect(response.statusCode).toEqual(500);

          const logsMessages = LogUtils.getLogsMessages();
          expect(logsMessages.join('\n')).toMatch(
            new RegExp(
```

```
            `Error: Request to URL '[^']*\/languages' exceeded expected time of
${BACKEND_TIMEOUT_TIME_LIMIT}ms and was aborted`
          )
        );
```

5.17 Log SSR come cause — projects/ssr-tests/src/environments/custom-test-environment.ts:L16-L44

```ts
export default class CustomTestEnvironment extends NodeEnvironment {
  // ...
  async handleTestEvent(event: Event, _state: State) {
    if (event.name === 'test_done') {
      event.test.errors = event.test.errors.map((errors) => {
        if (Array.isArray(errors)) {
          const [originalError, asyncError] = errors;

          const ssrLogs = getSsrLogs();
          // Error's `cause` property is the only property printed by Jest
          // besides `message` that we can utilize for attaching logs.
          // No other custom properties are printed by Jest.
          // ...
          addCauseToError({
            error: originalError, // e.g. error when an expect() fails
            cause: ssrLogs,
          });
          addCauseToError({
            error: asyncError, // e.g. error when a test timeout happens
            cause: ssrLogs,
          });
        }
        return errors;
      });
    }
  }
}
```

5.18 Module boundaries — eslint.config.mjs:L129-L154

```js
      '@nx/enforce-module-boundaries': [
        'error',
        {
          allow: [],
          allowCircularSelfDependency: true,
          depConstraints: [
            {
              sourceTag: '*',
```

```
            onlyDependOnLibsWithTags: ['*'],
            notDependOnLibsWithTags: [TAG.APP],
          },
          {
            sourceTag: TAG.FEATURE,
            notDependOnLibsWithTags: [TAG.INTEGRATION],
          },
          {
            sourceTag: TAG.UI,
            notDependOnLibsWithTags: [TAG.FEATURE],
          },
          {
            sourceTag: TAG.CORE,
            notDependOnLibsWithTags: [TAG.UI, TAG.FEATURE],
          },
        ],
      },
    ],
```

5.19 Sequenza di `config:check` — `tools/config/index.ts:L327-L347`

TS

```ts
// Run the cheap lock-file check first so a PR that forgot to update its
// `package-lock.json` fails fast, without waiting for the slower dependency,
// tsconfig and `generate:deps` steps below.
checkLockFiles(options);
if (!options.fix && errorsCount > 0) {
  console.log(chalk.red(`\nErrors: ${errorsCount}\n`));
  process.exit(1);
}

manageDependencies(repository, options);
// Keep it after dependencies, because fixes from deps might might result in different tsconfig files
manageTsConfigs(repository, options);
syncAiMigrationVersion();

if (options.generateDeps) {
  // re-generate dependencies.json file.
  execSync(`npm run generate:deps`);
} else {
  // collect and generate dependencies.json file.
  execSync(`npm run generate:deps -- --compare`);
}
```

7. Commenti e note notevoli dal sorgente

- "This file is required by karma.conf.js and loads recursively all the .spec and framework files" (`core-libs/core/src/test.ts:L7-L7`). Allo SHA è falso per core, che non ha più `karma.conf.js` (trappola 1).
- "Should be used with caution, and only if there is no other way to mock stuff (eg. by DI)" (`core-libs/core/src/test.ts:L10-L10`): la patch di `defineProperty` è dichiarata un'ultima risorsa.

- "//No longer necessary under vitest" (`core-libs/core/src/test.ts:L26-L26`): una nota di migrazione lasciata nel codice.
- "This file should NOT be imported in the production code, but only in unit tests!" (`testing/patch-object-define-property.ts:L11-L11`).
- "NOTE: order matters. Vite matches string aliases in order (first match wins) ..." (`core-libs/storefront/vitest.config.ts:L16-L19`).
- "// ensure the deprecated DOM changes are not rendered during tests" (`core-libs/storefront/shared/test/mock-feature-directive.ts:L17-L17`): il mock assume una convenzione (`!` = ramo deprecato) e non legge i toggle.
- "// empty, for now" (`core-libs/styles/test-jest.ts:L7-L7`).
- "mapping required to use `beasties` from node modules ..." e "Jest treats .mjs as ESM and double-wraps the default export ..." (`core-libs/setup/jest.config.js:L12-L24`): due workaround di interoperabilità ESM/CJS legati a issue Angular CLI linkate nel commento.
- La JSDoc del `globalSetup` elenca le tre precondizioni e contiene il refuso "The app us built" (`projects/ssr-tests/validate-ssr-build.ts:L7-L31`). La JSDoc del marker proxy è corrotta da un replace: "String that always USING_DEV_MODE_MARKER in the `main.js` ..." (`projects/ssr-tests/validate-ssr-build.ts:L48-L48`).
- "Error's `cause` property is the only property printed by Jest besides `message` ..." (`projects/ssr-tests/src/environments/custom-test-environment.ts:L26-L29`).
- "Note: `TestConfigModule` of Spartacus will read this cookie ..." (`projects/ssr-tests/src/utils/http.utils.ts:L79-L80`).
- "path to the page that is less "busy" than the homepage" (`projects/ssr-tests/src/ssr-testing.spec.ts:L12-L12`).
- "Shared unit-test sharding helpers, sourced by both CI pipelines" (`ci-scripts/shard-lib.sh:L3-L7`).
- "--json is passed explicitly: `nx show projects` output is environment-dependent (JSON array locally, newline plaintext on non-TTY CI runners)" (`ci-scripts/shard-lib.sh:L11-L12`).
- "Weight = total lines across the project's *.spec.ts files (a better runtime proxy than file count)" (`ci-scripts/shard-lib.sh:L30-L32`).
- "Run the cheap lock-file check first so a PR that forgot to update its `package-lock.json` fails fast" (`tools/config/index.ts:L327-L329`).
- "To make sure we get an accurate diff, do not update the dependencies of this tool ..." (`tools/breaking-changes/readme.md:L3-L3`).
- "#Force run vendor tests." è un blocco commentato in `e2e-cypress.sh` (`ci-scripts/e2e-cypress.sh:L199-L204`).
- "We've imported your old cypress plugins here. You may want to clean this up later" (`projects/storefrontapp-e2e-cypress/cypress.config.ts:L41-L42`): residuo della migrazione automatica a Cypress 10+.

---

8. Extension point

Questo capitolo riguarda tooling interno: nessuno dei simboli qui sotto è nel public API delle librerie pubblicate. Sono punti di estensione **per chi contribuisce al monorepo** o per chi copia gli schemi nel proprio progetto.

PUNTO	TIPO	DEFINIZIONE	NOTE
`MockFeatureDirective`, `MockFeatureLevelDirective`, `MockFeatureDirectivesModule`, `MockMediaComponent`, `MockWinRef`	mock di test	`core-libs/storefront/shared/test/index.ts:L7-L11`	non esportati da `core-libs/storefront/public_api.ts`; si raggiungono con gli alias `@spartacus/storefront/testing/...` (`core-libs/storefront/tsconfig.spec.json:L16-L32`)
`provideMockFeatureToggles(initial)`, `MockFeatureTogglesController`	provider di test	`core-libs/core/src/features-config/feature-toggles/testing/mock-feature-toggles.ts:L150-L184`	alias `@spartacus/core/testing/feature-toggles` (`core-libs/storefront/vitest.config.ts:L20-L20`). Non esiste un entry point `testing` pubblicato: l'unico `ng-package.json` di core è `core-libs/core/ng-package.json` e `core-libs/core/public_api.ts` non esporta `testing`; l'alias vive solo nelle config di test, e `**/testing/**` è esclusa dalla coverage (`core-libs/core/vitest.config.ts:L38-L38`)
Nuova lib testata con Vitest	convenzione	target `test-vitest` (`nx:run-commands`) + `vitest.config.ts` + `tsconfig.spec.json`, modello `core-libs/core/project.json:L20-L26`	viene inclusa da sola nello sharding, perché l'enumerazione è per target (`ci-scripts/compute-unit-shards.sh:L31-L31`)
Regola ESLint del workspace	file in `tools/eslint-rules/rules/`	registrazione in `tools/eslint-rules/index.ts:L61-L101`	attivazione in `eslint.config.mjs` con prefisso `@nx/workspace-` (`eslint.config.mjs:L250-L258`); test con `RuleTester`
Regola stylelint	plugin	`tools/stylelint-rules/index.js:L9-L11`	attivata in `.stylelintrc.json:L3-L5`
Builder ng-packagr custom	builder Angular	`tools/build-lib/builders.json:L1-L14`	referenziato come `./tools/build-lib:<name>` (`core-libs/core/project.json:L9-L9`)
`ProxyOptions.responseInterceptor`	callback	`projects/ssr-tests/src/utils/proxy.utils.ts:L27-L50`	simula status code, ritardi e body del backend negli E2E SSR
`TestRequest.testConfig`	config iniettata	`projects/ssr-tests/src/utils/http.utils.ts:L27-L37`	varia toggle o timeout senza ribuildare l'app
`cy.cxConfig(config)`	comando Cypress	`projects/storefrontapp-e2e-cypress/cypress/support/cx-config.commands.ts:L21-L28`	stesso cookie letto da `TestConfigModule` (`projects/storefrontapp/src/app/private/private.providers.ts:L54-L54`)

Come aggiungere uno scenario SSR (schema basato sui test esistenti):

```ts
// dentro un describe che in beforeEach chiama SsrUtils.startSsrServer(...)
it('should ... when <API> fails', async () => {
  backendProxy = await ProxyUtils.startBackendProxyServer({
    target: BACKEND_BASE_URL,
    responseInterceptor: ({ res, req, body }) => {
```

```
      if (req.url?.includes('<frammento URL OCC>')) {
        res.statusCode = 500;
      }
      res.end(body); // obbligatorio: l'interceptor gestisce la risposta
    },
  });
  const response = await HttpUtils.sendRequestToSsrServer({
    path: REQUEST_PATH,
    testConfig: { /* chunk di Config opzionale */ },
  });
  expect(response.statusCode).toEqual(500);
  expect(LogUtils.getLogsMessages()).toContain(`...`);
});
```

Ogni chiamata usata nello schema esiste in projects/ssr-tests/src/ssr-testing.spec.ts:L52-L82 (interceptor e sendRequestToSsrServer), projects/ssr-tests/src/ssr-testing.spec.ts:L114-L119 (testConfig) e projects/ssr-tests/src/ssr-testing.spec.ts:L35-L36 (LogUtils.getLogsMessages() + toContain). L'afterEach di file chiude già proxy e server (projects/ssr-tests/src/ssr-testing.spec.ts:L14-L17).

Ricette pertinenti della Parte III:

- 50 — Ricette: configurazione, DI, interceptor, eventi: ogni override via DI (service, facade, interceptor) si verifica con gli stessi strumenti del §3.6 (TestBed, provideHttpClientTesting, vi.spyOn); provideMockFeatureToggles serve per i toggle.
- 51 — Ricette: componenti CMS, outlet, route e layout: per testare un componente CMS sostituito o esteso si usa lo schema overrideComponent + mock (MockFeatureDirective, MockMediaComponent) del test del banner.
- 52 — Ricette: OCC, adapter, converter, endpoint, meta resolver: un adapter custom si testa come occ-product-reviews.adapter.spec.ts (HttpTestingController, ConverterService spiato). Il proxy degli E2E SSR mostra come simulare errori OCC end-to-end.
- 53 — Ricette: feature lib lazy, carrello/checkout, stili, traduzioni: per gli override SCSS con forFeature si può riusare l'approccio sass-true del §3.4.
- 54 — API pubblica vs interna, upgrade, anti-pattern, checklist: tools/breaking-changes (API Extractor) e le regole ESLint (private per FeatureToggles, protected per gli inject()) spiegano perché certe API restano stabili e altre no.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. test.ts **orfano in core.** core-libs/core/src/test.ts dichiara di servire karma.conf.js, ma core non ha più né target test né karma.conf.js. Il file sopravvive solo come esclusione in tsconfig.lib.json (core-libs/core/project.json:L7-L36, core-libs/core/tsconfig.lib.json:L24-L24). Dice anche "Has to be imported just after zone.js imports" senza importare zone.js (core-libs/core/src/test.ts:L11-L14).
2. **Il commento di** $TEST_RUNNER **mente.** Dice "karma → Jasmine/Karma (+ Jest schematics)", ma il case ha un ramo jest separato e il ramo karma non lancia Jest (ci-scripts/unit-tests.sh:L9-L9, ci-scripts/unit-tests.sh:L90-L95).

3. **Ramo affected irraggiungibile in CI.** La matrice valorizza sempre `$UNIT_TEST_GROUP_PROJECTS`, quindi `run_affected_unit_tests` di `unit-tests.sh` non viene mai eseguito: l'affected è gestito a monte in `compute-unit-shards.sh` (ci-scripts/unit-tests.sh:L108-L115, .github/workflows/ci-continuous-integration.yml:L69-L69). Fuori dalla CI lo script resta usabile da solo.
4. `eslint-rules` **nella shard "Karma".** Ha un target `test` (executor `@nx/jest:jest`), quindi rientra tra i progetti enumerati per `test` e riceve gli argomenti Karma (`--no-watch --browsers ChromeHeadless ...`) (tools/eslint-rules/project.json:L7-L14, ci-scripts/compute-unit-shards.sh:L22-L25). DA VERIFICARE l'effetto reale: senza `node_modules` non si può eseguire nx.
5. **Script npm e istruzioni obsoleti.** `test:libs` mescola `nx test-vitest` e `nx test <lib> --code-coverage` per lib già migrate (`cdc`, `s4-service`, `cdp`, `digital-payments`, `cpq-quote`), che non hanno target `test` (package.json:L147-L147, integration-libs/cdc/project.json:L20-L27). Per `setup` il target `test` deriva verosimilmente dallo script npm Jest (core-libs/setup/package.json:L16-L16, core-libs/setup/project.json:L20-L26), e infatti la CI lo tratta come JEST_ONLY (ci-scripts/compute-unit-shards.sh:L20-L20) (DA VERIFICARE, vedi trappola 6). Lo stesso vale per `test:storefront:lib` (`nx test storefrontlib`) (package.json:L148-L148, core-libs/storefront/project.json:L21-L27) e per le istruzioni di progetto, che citano ancora `nx run storefrontlib:test` (.claude/CLAUDE.md:L26-L41). Il comando giusto è `nx test-vitest <lib>` oppure `npx vitest run --config <lib>/vitest.config.ts <spec>`.
6. `nx test ssr-tests`**.** `test:ssr` invoca il target `test`, ma `ssr-tests` definisce solo `lint` e `test-jest` (package.json:L156-L157, projects/ssr-tests/project.json:L6-L20). `nx.json` ha un `targetDefaults.test`, ma contiene solo `cache: true`: non definisce un executor e da solo non crea il target (nx.json:L15-L17); inoltre `useInferencePlugins` è `false` (nx.json:L22-L22). `projects/ssr-tests/package.json` ha però lo script `test` → `jest --config ./jest.config.js` (projects/ssr-tests/package.json:L14-L14), e la CI esclude `ssr-tests` dall'enumerazione `--with-target=test` (ci-scripts/compute-unit-shards.sh:L19-L19, ci-scripts/unit-tests.sh:L5-L5): segno che Nx espone lo script npm come target `test`. Anche il job CI passa di lì: `test_ssr` → `npm run test:ssr:ci` → `nx test ssr-tests` (ci-scripts/npm-commands.sh:L45-L60, package.json:L157-L157). DA VERIFICARE che `nx test ssr-tests` si risolva sullo script npm `test`: non è eseguibile staticamente (`node_modules` assente).
7. **Cache nx solo per** `test`**.** `nx.json` mette in cache `test` ma non `test-vitest`/`test-jest`, che sono `nx:run-commands` senza `targetDefaults`. Salvo config per progetto (non trovata in core e storefront), i run Vitest/Jest non sono cacheati (nx.json:L15-L17, core-libs/core/project.json:L20-L26).
8. `restoreMocks` **non uniforme.** È presente solo in 4 dei 32 `vitest.config.ts` (core, storefront, user, cdc); manca ad esempio in `asm` (core-libs/core/vitest.config.ts:L18-L18, feature-libs/asm/vitest.config.ts:L21-L28). In una lib senza `restoreMocks` uno `vi.spyOn` che non viene ripristinato può influenzare i test successivi dello stesso file: di qui la regola di progetto sul reset in `afterEach` (.claude/CLAUDE.md:L48-L50).
9. **Esclusioni di coverage sbagliate in core.** La config esclude `'../../testing/setup-test.ts'`, che non esiste (il file reale è `setup-vitest.ts`), e `textfield/root/**`, cartella che non appartiene a core (core-libs/core/vitest.config.ts:L41-L42).
10. `MockWinRef` **dipende da Vitest.** Importa `vi` da `vitest`, quindi le lib ancora su Karma/Jasmine non possono usarlo (core-libs/storefront/shared/test/mock-window-ref.ts:L7-L7).
11. **Alias** `mock-media` **solo nel tsconfig.** `@spartacus/storefront/testing/mock-media` è nei `paths` di `tsconfig.spec.json` ma non tra gli alias di `storefront/vitest.config.ts`; a runtime la risoluzione dipende da `nxViteTsPaths()` (core-libs/storefront/tsconfig.spec.json:L23-L25, core-libs/storefront/vitest.config.ts:L14-L35). DA VERIFICARE quale tsconfig legga il plugin (root o `tsconfig.spec.json`): il codice di `@nx/vite` non è disponibile allo SHA.
12. `MockFeatureDirective` **non copre i rami** `!toggle`**.** Qualunque argomento con `!` non viene renderizzato, a prescindere dal valore reale dei toggle (core-libs/storefront/shared/test/mock-feature-directive.ts:L19-L21). Per testare il ramo legacy serve la direttiva reale con `provideMockFeatureToggles` (vedi 42).

13. **sass-true e path relativi.** I `.spec.scss` importano `'../../sass-true/sass/true'`, che rispetto a `core-libs/styles/test/` punterebbe a una `core-libs/sass-true/` inesistente (core-libs/styles/test/features.spec.scss:L1-L1). `DA VERIFICARE` come sass-true risolva i load path: il pacchetto `sass-true@10` non è in `/tmp/deps`.
14. `it` **annidati per errore.** In `features.spec.scss` due `it` (L61 e L94) sono annidati dentro un altro `it` aperto a L37 e chiuso a L119, per una parentesi messa male (core-libs/styles/test/features.spec.scss:L37-L119).
15. **Glob relativo alla cwd.** `scss.spec.js` risolve `test/**/*.spec.scss` rispetto a `process.cwd()`, quindi funziona solo se Jest parte da `core-libs/styles`, come fa il target nx (core-libs/styles/test/scss.spec.js:L5-L5, core-libs/styles/project.json:L10-L10). Lanciato da un'altra cartella, fallisce il test sentinella.
16. **Porte fisse e un server alla volta.** SSR su 4000 (validate, http.utils, default di ssr.utils) e proxy su 9002, entrambe hardcoded: i test SSR non si possono parallelizzare (projects/ssr-tests/validate-ssr-build.ts:L40-L40, projects/ssr-tests/src/utils/http.utils.ts:L13-L16, projects/ssr-tests/src/utils/proxy.utils.ts:L112-L112). Il processo figlio vive in una variabile di modulo, e `killSsrServer` fallisce se `startSsrServer` non è stato chiamato (projects/ssr-tests/src/utils/ssr.utils.ts:L40-L40, projects/ssr-tests/src/utils/ssr.utils.ts:L67-L69).
17. **Polling senza timeout proprio.** `waitUntilLogContainsText` termina solo quando il testo compare o quando scade il timeout Jest (projects/ssr-tests/src/utils/log.utils.ts:L82-L99). La ricorsione non ripassa `checkInterval`, quindi un intervallo custom vale solo per il primo controllo (projects/ssr-tests/src/utils/log.utils.ts:L94-L97). Se il server non parte (build mancante, errore di bootstrap), il test fallisce per timeout, non con un messaggio esplicito.
18. **Marker fragile.** Il controllo del proxy cerca la stringa esatta `CX_BASE_URL:"http://localhost:9002"` nei bundle minificati di primo livello: `getFiles` non è ricorsiva, e un cambio di minificazione o di naming rompe il controllo (projects/ssr-tests/validate-ssr-build.ts:L50-L50, projects/ssr-tests/validate-ssr-build.ts:L92-L108).
19. **Cookie "vuoto" malformato.** Senza `testConfig`, `buildCxConfigE2ECookie` restituisce `'{}'` come intero header `Cookie`, non una coppia `nome=valore` (projects/ssr-tests/src/utils/http.utils.ts:L82-L85).
20. **Timeout "lungo" uguale al default.** Il `describe` "With long SSR request timeout" passa `timeout: 20_000`, che coincide con `DEFAULT_SSR_TIMEOUT` (projects/ssr-tests/src/ssr-testing.spec.ts:L85-L90, projects/ssr-tests/src/utils/ssr.utils.ts:L17-L17).
21. **Consigli di build divergenti.** L'errore del `globalSetup` suggerisce `npm run build && ...`, il README `npm run build:libs && ...` (projects/ssr-tests/validate-ssr-build.ts:L63-L65, projects/ssr-tests/README.md:L7-L7).
22. `moduleNameMapper` **vuoto in ssr-tests.** `jest.config.js` legge `compilerOptions.paths` dal proprio `tsconfig.json`, che non li definisce: li erediterebbe via `extends`, ma `require` non risolve `extends` (projects/ssr-tests/jest.config.js:L1-L8, projects/ssr-tests/tsconfig.json:L1-L23).
23. **Falsi positivi e negativi in** `validate-lint.sh`**.** Il grep `'fit('` colpisce anche identificatori che finiscono in "fit(" come `benefit(` (ci-scripts/validate-lint.sh:L53-L53). Il check prettier fallisce solo se l'**ultima** riga di output contiene `projects`, quindi un file non formattato fuori da `projects/` in ultima posizione passa (ci-scripts/validate-lint.sh:L98-L99). Il messaggio di `validateTsConfigFile` usa `$LOCAL_ENV_LIB_PATH`, definita dopo la funzione: funziona solo per l'ordine di esecuzione (ci-scripts/validate-lint.sh:L15-L15, ci-scripts/validate-lint.sh:L28-L30).
24. **ESLint cieco su Cypress e Vitest config.** `projects/storefrontapp-e2e-cypress/**` e tutti i `vitest.config.ts` sono ignorati (eslint.config.mjs:L21-L26).
25. **Glob Cypress "full" senza i core.** Il pattern `--spec "...*.e2e.cy.ts"` (es. `cy:run:ci`) non corrisponde ai file `*.core-e2e.cy.ts`, perché prima di `e2e` c'è `-` invece di `.`. La suite "full" quindi non include gli spec core, mentre `cy:run:ci:b2b` usa `*e2e.cy.ts` e li include (projects/storefrontapp-e2e-cypress/package.

json:L24-L24, projects/storefrontapp-e2e-cypress/package.json:L30-L30, projects/storefrontapp-e2e-cypress/package.json:L36-L36). DA VERIFICARE se sia intenzionale: dipende dal processo del team.

26. **Script Cypress del layout < 10.** `cy:run:ci:cdc-b2b` e `cy:run:ci:vendor:cdc-b2b` usano `--config-file cypress.ci.json` e `cypress/integration/...` (projects/storefrontapp-e2e-cypress/package.json:L40-L40, projects/storefrontapp-e2e-cypress/package.json:L52-L52).
27. **a11y: recording contro round-robin.** Con `ENABLE_A11Y_RECORDING: true`, impostato in `ci.yml`, ogni container lancia l'intera suite a11y affidandosi a `--parallel` della Dashboard; `test-distribution.sh` si usa solo senza recording (.github/workflows/ci.yml:L297-L298, ci-scripts/e2e-a11y-helpers.sh:L78-L90). Anche con `--skip-build`, la parte B2B ribuilda l'app (ci-scripts/e2e-a11y-helpers.sh:L47-L52, ci-scripts/e2e-a11y-helpers.sh:L114-L115). Per la suite a11y lo script forza `SPA_ENV='ci,b2c'`, sovrascrivendo quello del job (ci-scripts/e2e-cypress.sh:L78-L80).
28. **`$RUN_E2E` solo su PR.** `validate-e2e-execution.sh` imposta `$RUN_E2E` solo se `$GITHUB_BASE_REF` è valorizzata; su `push` resta `false`, e i job e2e di `ci.yml` partono comunque grazie alla condizione `github.event_name == 'push'` (ci-scripts/validate-e2e-execution.sh:L5-L7, .github/workflows/ci.yml:L122-L122). Poiché `ci.yml` scatta solo su `push`/`workflow_dispatch` (.github/workflows/ci.yml:L1-L9), lì `$RUN_E2E` è sempre `false`: il gating vale davvero solo in `ci-merge-checks.yml`, che esegue lo script su PR `ready_for_review` e condiziona build ed e2e a `SHOULD_RUN_E2E == 'true'` (.github/workflows/ci-merge-checks.yml:L1-L7, .github/workflows/ci-merge-checks.yml:L59-L68).
29. **Versioni divergenti nei tool.** Il `package.json` root dice `2612.0.0`, `PUBLISHING_VERSION` dice `221121.22.0`, `tools/breaking-changes` usa `NEW_VERSION = '221121_7'` e il suo readme cita `'2211.19'` (package.json:L3-L3, tools/config/const.ts:L13-L13, tools/breaking-changes/common.ts:L12-L12, tools/breaking-changes/readme.md:L10-L10). Il commento di `tsconfig-paths.ts` cita inoltre `ts-node ./tools/tsconfig-paths/index.ts`, path inesistente: l'entry reale è `tools/config/index.ts` (tools/config/tsconfig-paths.ts:L15-L15, package.json:L63-L63).

---

10. Come fare debug

- **Un singolo spec Vitest.** `npx vitest run --config <lib>/vitest.config.ts <path-spec>` (.claude/CLAUDE.md:L37-L41), oppure `nx test-vitest <lib>`, che esegue lo stesso comando con cwd sulla lib (core-libs/core/project.json:L20-L26). La coverage è sempre attiva (core-libs/core/vitest.config.ts:L26-L26), quindi su un singolo file le soglie 85/85/65/85 possono fallire anche se i test passano. Le istruzioni di progetto suggeriscono anche `--sequence.shuffle` per scoprire dipendenze dall'ordine e `--detect-async-leaks` per gli async non risolti (.claude/CLAUDE.md:L44-L46).
- **Import non risolto sotto Vitest.** Controlla nell'ordine gli alias di `resolve.alias` (deep path prima di quelli generici: core-libs/storefront/vitest.config.ts:L16-L19) e poi i `paths` del `tsconfig.spec.json` della lib (feature-libs/cart/tsconfig.spec.json:L35-L40). Storefront mappa `@spartacus/core` sul sorgente (core-libs/storefront/vitest.config.ts:L25-L28); la motivazione non è dichiarata nel codice, ma verosimilmente serve a evitare due copie dello stesso token DI (una da `dist`, una dal sorgente), causa tipica di mock "ignorati".
- **NG0100 sotto Karma.** Verifica che il `test.ts` registri `ZoneChangeDetectionModule` come in integration-libs/opf/test.ts:L9-L32. Sotto Vitest non serve (core-libs/core/src/test.ts:L26-L26).
- **Quale shard ha eseguito un progetto.** Ogni gruppo stampa nel log CI l'elenco dei progetti preceduto da `[KARMA]/[JEST]/[VITEST] Group will run N project(s):` (ci-scripts/unit-tests.sh:L18-L28). In locale `ci-scripts/compute-unit-shards.sh` stampa la matrice JSON (ci-scripts/compute-unit-shards.sh:L53-L63). Servono `jq` e nx funzionante.

- **E2E SSR che non parte.** Leggi il messaggio del `globalSetup`: nomina la condizione violata e suggerisce il comando di build o quello per liberare la porta (projects/ssr-tests/validate-ssr-build.ts:L63-L81, projects/ssr-tests/validate-ssr-build.ts:L83-L141). Se il test va in timeout, apri `projects/ssr-tests/.ssr.log`, dove finiscono stdout e stderr del server (projects/ssr-tests/src/utils/ssr.utils.ts:L56-L56). Su asserzione fallita, i log sono già nella `cause` stampata da Jest, tra `--- SSR LOGS (with JSONs pretty-printed) ---` e `--- SSR LOGS END ---` (projects/ssr-tests/src/environments/custom-test-environment.ts:L58-L60). Se resta un processo orfano sulla 4000: `kill -9 $(lsof -t -i :4000)`, come suggerito da `KILL_PORT_ADVICE` (projects/ssr-tests/validate-ssr-build.ts:L70-L81).
- **Backend CCv2 dietro il proxy.** Imposta a mano `IS_CCV2_SERVER = true` per usare un `HttpsAgent` con SNI (projects/ssr-tests/src/utils/proxy.utils.ts:L13-L17, projects/ssr-tests/src/utils/proxy.utils.ts:L66-L71).
- **Config dinamica negli E2E.** In SSR passa `testConfig` (projects/ssr-tests/src/utils/http.utils.ts:L27-L37), in Cypress `cy.cxConfig(...)` (projects/storefrontapp-e2e-cypress/cypress/support/cx-config.commands.ts:L26-L28). Funzionano solo con un'app che importa `TestConfigModule.forRoot({ cookie: 'cxConfigE2E' })`, come quella demo (projects/storefrontapp/src/app/private/private.providers.ts:L54-L54).
- **Test SCSS.** Lancia sempre da `core-libs/styles` (`nx run storefrontstyles:test-jest`, core-libs/styles/project.json:L6-L12). Se il runner dice che non ci sono file, il problema è la cwd (trappola 15).
- **Lint rosso in CI ma non in locale.** Esegui `ci-scripts/validate-lint.sh` per intero: i grep anti-focus e il check su `tsconfig.app.prod.json` non fanno parte di `npm run lint` (ci-scripts/validate-lint.sh:L28-L80, package.json:L128-L131).
- **Dipendenze o tsconfig incoerenti.** `npm run config:check` riporta errori e warning; `npm run config:update` prova a correggerli, rigenera il lock file e formatta (package.json:L62-L64, tools/config/index.ts:L349-L371).

---

11. Domande di autoverifica

1. **Con quale runner si testano allo SHA `core` e `storefrontlib`, e con quale comando?** Con Vitest, tramite il target `test-vitest` → `npx vitest run --config vitest.config.ts` nella root della lib. Non hanno un target `test`. — core-libs/core/project.json:L20-L26, core-libs/storefront/project.json:L21-L27
2. **Perché una lib come `cart` ha due target di test?** `test-vitest` esegue gli unit test, `test-jest` esegue gli schematics (`npm run test:schematics`) con Jest. — feature-libs/cart/project.json:L20-L32, core-libs/schematics/jest.schematics.config.js:L1-L23
3. **Come decide la CI quanti e quali progetti mettere in ogni shard?** Enumera i progetti per target con `nx show projects --with-target`, pesa ognuno con le righe significative dei suoi `*.spec.ts` e li distribuisce con un greedy LPT sul bucket meno carico. — ci-scripts/compute-unit-shards.sh:L19-L51, ci-scripts/shard-lib.sh:L30-L71
4. **Perché il `test.ts` Karma registra `provideZoneChangeDetection()` e `setup-vitest.ts` no?** Con un `test.ts` custom Angular 21 produce errori NG0100 sotto Karma; il commento annota che sotto Vitest non serve più. — core-libs/core/src/test.ts:L21-L30, testing/setup-vitest.ts:L16-L19
5. **In un test di storefront, perché l'alias `@spartacus/storefront/testing/mock-feature-directive` deve stare prima di `@spartacus/storefront`?** Vite usa il primo alias che corrisponde, e quello "nudo" catturerebbe anche il deep path. — core-libs/storefront/vitest.config.ts:L16-L19
6. **Come fanno gli E2E SSR a simulare un errore del backend OCC senza modificare il backend?** L'app è buildata con `CX_BASE_URL=http://localhost:9002`. Su quella porta il test avvia un `http-proxy` verso il bac-

kend reale, il cui `responseInterceptor` può cambiare status code o ritardare la risposta. — `.env-cmdrc:L11-L13`, `projects/ssr-tests/src/utils/proxy.utils.ts:L58-L115`, `projects/ssr-tests/src/ssr-testing.spec.ts:L52-L82`

7. **Come si cambia la configurazione Spartacus di un'app SSR già buildata, per un singolo test?** Passando `testConfig` a `sendRequestToSsrServer`: diventa il cookie `cxConfigE2E`, che `TestConfigModule` dell'app inietta nella config globale. — `projects/ssr-tests/src/utils/http.utils.ts:L27-L37`, `projects/ssr-tests/src/utils/http.utils.ts:L75-L89`, `projects/storefrontapp/src/app/private/private.providers.ts:L54-L54`
8. **Dove si trovano i log del server SSR quando un test fallisce?** Nella `cause` dell'errore stampato da Jest, aggiunta da `CustomTestEnvironment` su `test_done`, e nel file `.ssr.log`. — `projects/ssr-tests/src/environments/custom-test-environment.ts:L19-L43`, `projects/ssr-tests/src/utils/log.utils.ts:L18-L18`
9. **Che cosa blocca `validate-lint.sh` che `npm run lint` non controlla?** I focus test (`fdescribe(`, `describe.only(`, `fit(`, `it.only()`), il self-import di storefrontlib e un `tsconfig.app.prod.json` che punta ai sorgenti invece che a `dist`. — `ci-scripts/validate-lint.sh:L11-L80`
10. **Come si testa un mixin SCSS in questo repo?** Con un file `test/*.spec.scss` che usa i mixin di sass-true (`describe`, `it`, `assert`, `output`, `expect`). `scss.spec.js` lo scopre con `globSync` e lo esegue sotto Jest con `sassTrue.runSass`. — `core-libs/styles/test/features.spec.scss:L14-L35`, `core-libs/styles/test/scss.spec.js:L1-L15`
11. **Perché `MockWinRef` non si può usare in `integration-libs/opf`?** Importa `vi` da `vitest`, mentre `opf` gira ancora su Karma/Jasmine. — `core-libs/storefront/shared/test/mock-window-ref.ts:L7-L7`, `integration-libs/opf/project.json:L20-L28`
12. **Una regola `@nx/enforce-module-boundaries` impedisce a `core` di importare da `storefrontlib`: su quali tag si basa?** `core` ha `scope:core`, che non può dipendere da `type:ui`/`type:feature`; `storefrontlib` ha `type:ui`. — `eslint.config.mjs:L148-L151`, `core-libs/core/project.json:L37-L37`, `core-libs/storefront/project.json:L38-L38`

TAVOLA 44.1 **4.1 Unit test in CI: dalla matrice al runner**

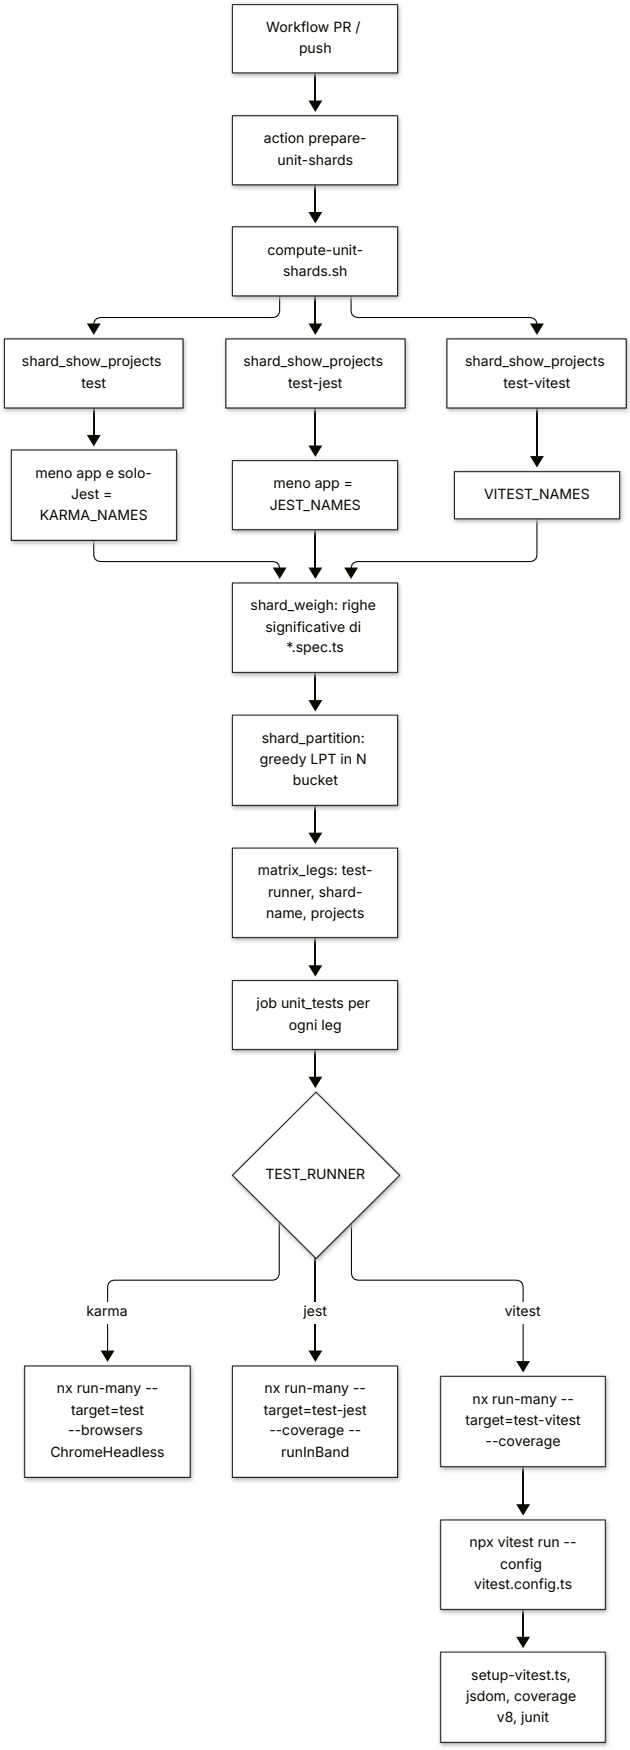

TAVOLA 44.2 **4.2 Un test E2E SSR con proxy e interceptor**

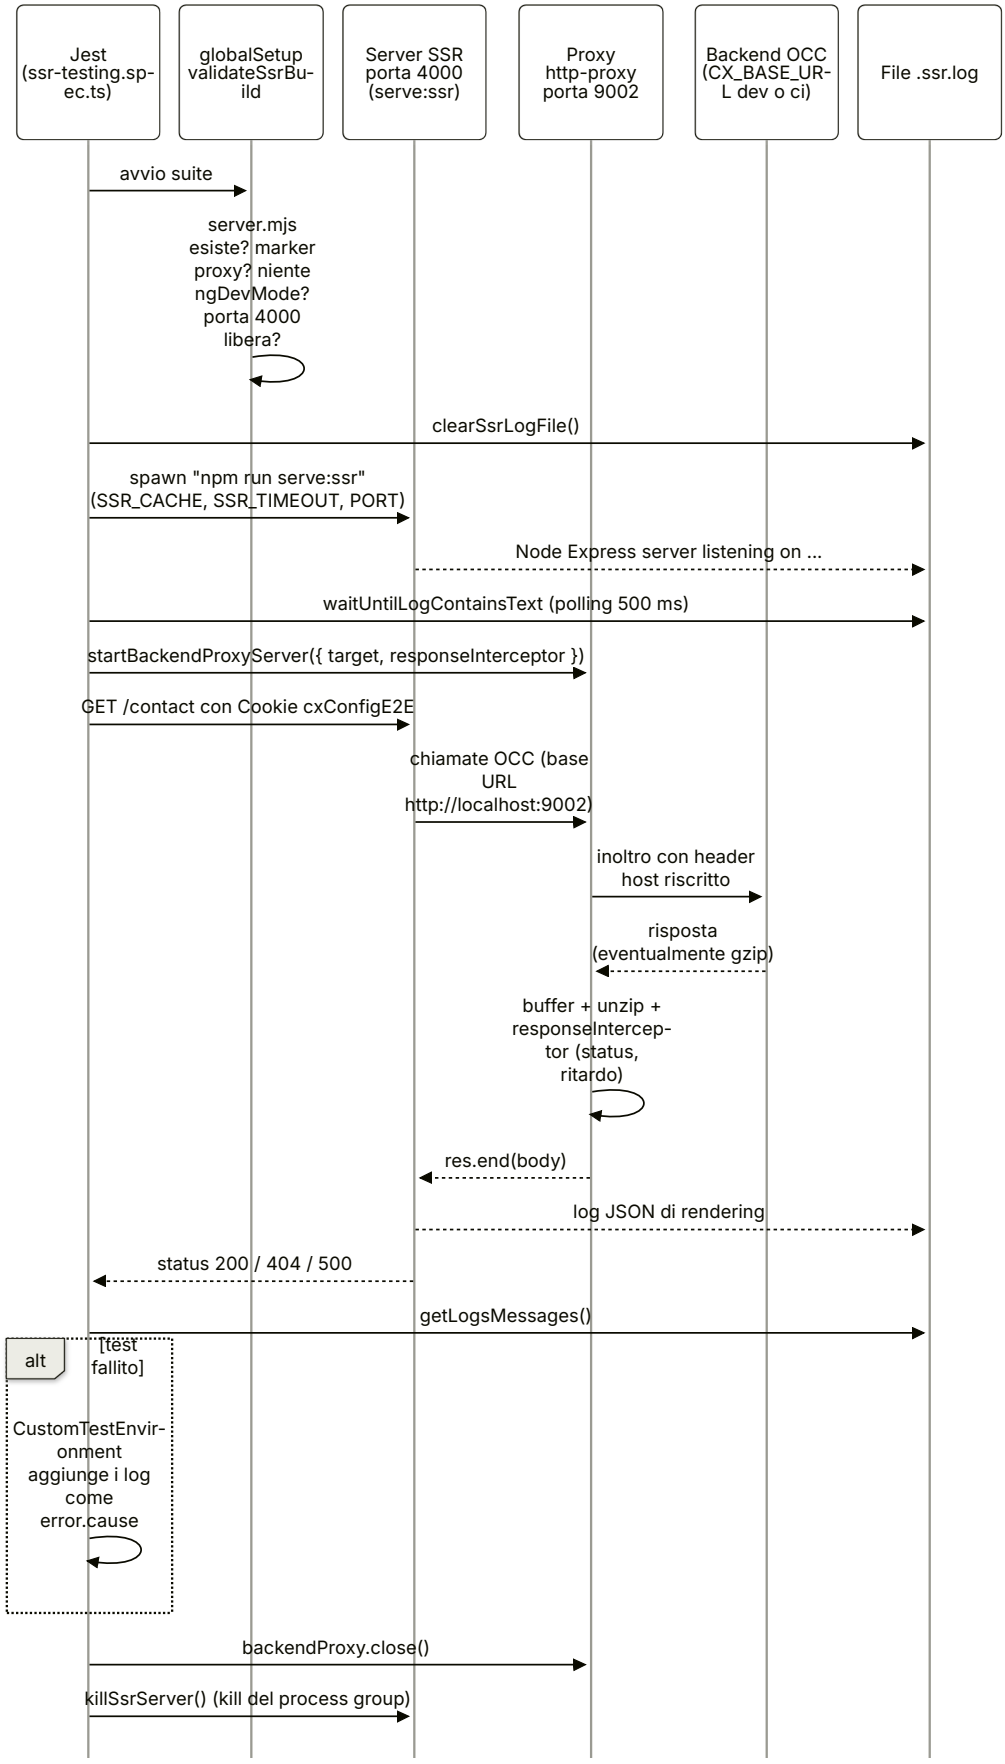

45

Componenti CMS e shared components di storefront

Componenti per i tipi CMS di base (dati, normalizzazione, link, a11y) e building block `shared/`.

IN QUESTO CAPITOLO

1. A cosa serve e perché esiste
2. Mappa dei file
3. Come funziona passo per passo
4. Diagrammi
5. Estratti di codice reale
6. Configurazione
7. Commenti e note notevoli dal sorgente
8. Extension point
9. Trappole, casi limite, comportamenti controintuitivi
10. Come fare debug
11. Domande di autoverifica

Riferimenti allo SHA `5b7a1c2bf2808d7380bc20596d10f4fa710c3da1` (vedi 00-meta).

I capitoli 15 e 16 spiegano come una pagina CMS arriva nello store e come `cxComponentWrapper` trasforma un `typeCode` in un componente Angular. Questo capitolo guarda *dentro* i componenti: quelli CMS "generici" di `@spartacus/storefront` (content, navigation, misc) e la cassetta degli attrezzi condivisa (`shared/`: media, carousel, generic link, form errors, item counter, pagination, popover, direttive, pipe, servizi file e validator) che tutte le feature lib riusano.

Lo scopo non è un catalogo esaustivo dei 286 file assegnati: si sceglie un componente rappresentativo per famiglia (Banner per content, NavigationService + NavigationUIComponent per navigation, Icon per misc, Media/Carousel/GenericLink per shared) e lo si segue fino alle righe di codice, mentre gli altri sono descritti per differenza. La tabella completa `typeCode → componente → modulo` di tutto il monorepo è nell'appendice A03.

---

1. A cosa serve e perché esiste

Il backend SAP Commerce restituisce componenti CMS con un `typeCode` (es. `SimpleResponsiveBannerComponent`, `CMSParagraphComponent`, `NavigationComponent`) e un sacco di proprietà quasi sempre **stringhe**. Lo storefront deve fornire, per ogni tipo "di base" previsto dal modello CMS standard, un componente Angular che:

1. riceva i dati tramite `CmsComponentData` (creato per ogni istanza da `CmsInjectorService.getInjector`, core-libs/storefront/cms-structure/page/component/services/cms-injector.service.ts:L28-L50);
2. **normalizzi** i dati CMS, che arrivano spesso con booleani come stringa: `data.external === 'true' || data.external === true` nel banner (core-libs/storefront/cms-components/content/banner/banner.component.ts:L133-L135), `data.autoPlay === 'true'` nel video (core-libs/storefront/cms-components/content/video/video.component.ts:L92-L96), `isBool(...)` nel search box (core-libs/storefront/cms-components/navigation/search-box/search-box.component.ts:L246-L266);
3. **risolva i link** CMS (URL assoluto, content page, prodotto, categoria) in qualcosa che il router Angular capisca, con la cascata `urlLink → contentPage → product → category` (core-libs/storefront/cms-components/content/banner/banner.component.ts:L137-L161);
4. renda il tutto accessibile (tastiera, ARIA) e compatibile SSR.

Accanto ai componenti CMS esiste la directory `shared/`: componenti *non* mappati su typeCode ma usati come building block da tutto il resto (`cx-media`, `cx-generic-link`, `cx-carousel`, `cx-item-counter`, `cx-form-errors`, `cx-pagination`, `[cxPopover]`, ...). `cms-components/index.ts` e `shared/index.ts` sono entrambi riesportati da `@spartacus/storefront` (core-libs/storefront/public_api.ts:L21-L21, core-libs/storefront/public_api.ts:L29-L29), quindi tutto ciò che vedete in questo capitolo è API pubblica salvo le eccezioni elencate nella sezione 9.

Il pattern architetturale ricorrente è: **componente standalone + NgModule "wrapper"** che importa il componente e registra il mapping con `provideDefaultConfig(<CmsConfig>{ cmsComponents: {...} })` (core-libs/storefront/cms-components/content/banner/banner.module.ts:L20-L47). Il modulo resta per retrocompatibilità e per portare con sé la configurazione di default; l'app demo li importa esplicitamente in `SpartacusFeaturesModule` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L184-L199).

2. Mappa dei file

Prefisso comune: `core-libs/storefront/`. I file sono raggruppati per cartella; dove una cartella contiene il trittico `.component.ts/.html/.module.ts` si indica solo la cartella.

2.1 `cms-components/` (content, navigation, misc)

PATH	RUOLO
`core-libs/storefront/cms-components/index.ts`	Barrel di tutti i gruppi CMS (anche myaccount/product/user, fuori capitolo)
`core-libs/storefront/cms-components/content/banner/`	`BannerComponent` per 3 typeCode, link risolto, LCP, frecce a11y
`core-libs/storefront/cms-components/content/banner-carousel/`	`BannerCarouselComponent` per `RotatingImagesComponent`: carousel di componenti CMS
`core-libs/storefront/cms-components/content/link/`	`LinkComponent` per `CMSLinkComponent` → `cx-generic-link`
`core-libs/storefront/cms-components/content/paragraph/`	`ParagraphComponent` per `CMSParagraphComponent`/`CMSTabParagraphComponent`: HTML trusted + click via router
`core-libs/storefront/cms-components/content/pdf/`	`PDFComponent` per `PDFDocumentComponent`
`core-libs/storefront/cms-components/content/video/`	`VideoComponent` CMS (sorgente, thumbnail, flag, link)
`core-libs/storefront/cms-components/content/tab/` (`tab.component.ts`, `tab.model.ts`, `tab.module.ts`, `tab.utils.ts`, `panel/`)	`cx-tab`: tab/accordion generico, **non** mappato su typeCode
`core-libs/storefront/cms-components/content/tab-paragraph-container/`	`TabParagraphContainerComponent` per `CMSTabParagraphContainer`
`core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts`	`NavigationService`: costruzione dell'albero `NavigationNode` dallo store CMS
`core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts` (+ `.html`)	`NavigationUIComponent` (`cx-navigation-ui`): flyout, hamburger, tastiera
`core-libs/storefront/cms-components/navigation/navigation/navigation-node.model.ts`	Modello di vista `NavigationNode`
`core-libs/storefront/cms-components/navigation/navigation/navigation.component.ts`	`NavigationComponent` CMS (usa `createNavigation`)
`core-libs/storefront/cms-components/navigation/category-navigation/`	`CategoryNavigationComponent`, unico mapping con `data` statici
`core-libs/storefront/cms-components/navigation/footer-navigation/`	`FooterNavigationComponent`, senza flyout
`core-libs/storefront/cms-components/navigation/breadcrumb/`	`BreadcrumbComponent` da `PageMetaService`
`core-libs/storefront/cms-components/navigation/page-header/` (+ `page-title.utils.ts`)	`PageTitleComponent` e util `getPageTitle`
`core-libs/storefront/cms-components/navigation/scroll-to-top/`	`ScrollToTopComponent`

PATH	RUOLO
core-libs/storefront/cms-components/navigation/search-box/	SearchBoxComponent, SearchBoxComponentService, eventi, outlet, HighlightPipe
core-libs/storefront/cms-components/misc/icon/	IconComponent, IconLoaderService, IconConfig, ICON_TYPE, config Font Awesome, IconTestingModule
core-libs/storefront/cms-components/misc/site-context-selector/	SiteContextSelectorComponent, LanguageCurrencyComponent, SiteContextComponentService
core-libs/storefront/cms-components/misc/site-theme-switcher/	SiteThemeSwitcherComponent + service
core-libs/storefront/cms-components/misc/global-message/	GlobalMessageComponent (nel layout, non CMS)
core-libs/storefront/cms-components/misc/message/	MessageComponent inline riutilizzabile
core-libs/storefront/cms-components/misc/promotions/	PromotionsComponent presentational

2.2 shared/

PATH	RUOLO
core-libs/storefront/shared/components/media/ (media.component.ts, media.service.ts, media.config.ts, media.model.ts, media.module.ts, media-sources.pipe.ts)	cx-media: immagini responsive img/picture, URL assoluti, lazy/eager, fetch priority
core-libs/storefront/shared/components/carousel/ (+ carousel.service.ts, focusable-carousel-item/)	cx-carousel a slide
core-libs/storefront/shared/components/carousel-scrolling/	carousel a scroll orizzontale
core-libs/storefront/shared/components/generic-link/ (+ generic-link-component.service.ts)	cx-generic-link: link interno (routerLink) o esterno (href)
core-libs/storefront/shared/components/item-counter/	cx-item-counter su FormControl esterno
core-libs/storefront/shared/components/form/ (form-errors, date-picker, file-upload, password-visibility-toggle, required asterisks/legend)	componenti form
core-libs/storefront/shared/components/list-navigation/ (pagination, sorting, total)	paginazione (PaginationBuilder), ordinamento ng-select, totale
core-libs/storefront/shared/components/popover/	[cxPopover], PopoverComponent, PopoverService, modello
core-libs/storefront/shared/services/positioning/positioning.service.ts	PositioningService: calcolo posizione popover
core-libs/storefront/shared/components/card/, spinner/, star-rating/, progress-button/, read-more/, truncate-text-popover/	presentational vari
core-libs/storefront/shared/components/table/, split-view/, chat-messaging/, captcha/, anonymous-consents-dialog/, assistive-technology-message/, ng-select-a11y/	componenti più complessi (mappati, non approfonditi qui)
core-libs/storefront/shared/directives/ (roving-tabindex/, horizontal-scrolling-position/)	direttive a11y e scroll
core-libs/storefront/shared/pipes/suplement-hash-anchors/	cxSupplementHashAnchors
core-libs/storefront/shared/services/file/	download file, CSV import/export, validator file

PATH	RUOLO
core-libs/storefront/shared/utils/ (validators/custom-form-validators.ts, forms/title-utils.ts)	validator e util form
core-libs/storefront/shared/config/ (form-config.ts, view-config.ts, default-form-config.ts)	config FormConfig / ViewConfig

3. Come funziona passo per passo

3.1 Il contratto comune: mapping, injector, data$

1. **Registrazione.** Ogni modulo wrapper registra uno o più typeCode. BannerModule mappa tre typeCode sullo stesso BannerComponent (core-libs/storefront/cms-components/content/banner/banner.module.ts:L20-L47); CmsParagraphModule mappa CMSParagraphComponent e CMSTabParagraphComponent su ParagraphComponent (core-libs/storefront/cms-components/content/paragraph/paragraph.module.ts:L22-L31); LinkModule mappa CMSLinkComponent (core-libs/storefront/cms-components/content/link/link.module.ts:L17-L21); BannerCarouselModule mappa RotatingImagesComponent (core-libs/storefront/cms-components/content/banner-carousel/banner-carousel.module.ts:L23-L29); PDF, Video e TabParagraphContainer seguono lo stesso schema (core-libs/storefront/cms-components/content/pdf/pdf.module.ts:L16-L22, core-libs/storefront/cms-components/content/video/video.module.ts:L27-L33, core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.module.ts:L31-L37). I moduli navigation mappano 1:1 typeCode omonimi (core-libs/storefront/cms-components/navigation/navigation/navigation.module.ts:L33-L39, core-libs/storefront/cms-components/navigation/breadcrumb/breadcrumb.module.ts:L29-L35, core-libs/storefront/cms-components/navigation/search-box/search-box.module.ts:L41-L47).
2. **Moduli senza mapping.** TabModule non registra nulla: cx-tab è un building block (core-libs/storefront/cms-components/content/tab/tab.module.ts:L13-L17). Anche GlobalMessageComponentModule, MessageComponentModule e PromotionsModule non hanno mapping; <cx-global-message> è scritto direttamente nel template di StorefrontComponent (core-libs/storefront/cms-components/misc/global-message/global-message.module.ts:L13-L17, core-libs/storefront/layout/main/storefront.component.html:L16-L16) e il modulo è importato da BaseStorefrontModule (core-libs/storefront/base-storefront.module.ts:L30-L30).
3. **Injector per istanza.** Quando il wrapper crea un componente, CmsInjectorService.getInjector(type, uid) costruisce un Injector con un provider CmsComponentData ({ uid, data$ }), provideLcpPresenceForCmsComponent() e i providers del mapping (core-libs/storefront/cms-structure/page/component/services/cms-injector.service.ts:L28-L50). CmsComponentData è il tipo con uid e data$ (core-libs/storefront/cms-structure/page/model/cms-component-data.ts:L10-L13).
4. **Dati statici + dati backend.** data$ è ComponentDataProvider.get(uid, type): se il mapping ha data, emette subito i dati statici (startWith) e poi {...static, ...backend}, quindi il backend sovrascrive (core-libs/storefront/cms-structure/page/component/services/component-data.provider.ts:L35-L59). Nel perimetro di questo capitolo solo CategoryNavigationComponent usa data (resetMenuOnClose: true, core-libs/storefront/cms-components/navigation/category-navigation/category-navigation.module.ts:L21-L30).
5. **Providers per componente.** SiteContextSelectorModule usa il campo providers del mapping per dare a ogni istanza CMS un proprio SiteContextComponentService costruito con CmsComponentData nelle deps, e fornisce *anche* il service a livello modulo (senza dati CMS) per l'uso standalone (core-libs/storefront/cms-components/misc/site-context-selector/site-context-selector.module.ts:L33-L52).

3.2 Content: Banner (rappresentativo)

1. `BannerComponent` è OnPush; `data$` deriva da `component.data$` con un `tap` che chiama `setRouterLink(data)` e copia `data.styleClasses` nella `@HostBinding('class')` (core-libs/storefront/cms-components/content/banner/banner.component.ts:L44-L57).
2. `setRouterLink` risolve in cascata (core-libs/storefront/cms-components/content/banner/banner.component.ts:L137-L161):
   - `urlLink` → usato così com'è;
   - `contentPage` → `cmsService.getPage({ id, type: PageType.CONTENT_PAGE }).pipe(take(1))` e poi `page?.label` (asincrono);
   - `product` → `urlService.transform({ cxRoute: 'product', params: { code } })`;
   - `category` → idem con route `category`.
3. `getTarget` restituisce `_blank` se `data.external` vale `'true'` o `true` (core-libs/storefront/cms-components/content/banner/banner.component.ts:L133-L135).
4. `getImage` distingue `Image` da `ImageGroup` con `'url' in data.media`; l'aria-label del link è `headline ?? altText` della prima immagine (core-libs/storefront/cms-components/content/banner/banner.component.ts:L163-L189).
5. Il template, dentro `*cxLcpContext`, ha due rami: con `routerLink` rende un `cx-generic-link` **vuoto** seguito da headline/media/content come fratelli; senza link rende un `div.no-link`. Headline e content usano `[innerHTML]`; `cx-media` riceve `elementType 'picture'` e `fetchPriority` dal contesto LCP (core-libs/storefront/cms-components/content/banner/banner.component.html:L1-L35). Il contesto LCP è trattato nel capitolo 16.
6. Con il toggle `a11yBannerArrowKeyNavigation` (default `false`, core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1114-L1114) il banner gestisce le frecce: cerca i sibling `cx-banner` nel parent e per ↑/↓ usa come passo il numero di colonne della prima riga, calcolato confrontando `getBoundingClientRect().top` con tolleranza di 1px (core-libs/storefront/cms-components/content/banner/banner.component.ts:L65-L127).

3.3 Content: gli altri per differenza

- **Paragraph.** Il contenuto passa prima dalla pipe `cxSupplementHashAnchors` e poi da `DomSanitizer.bypassSecurityTrustHtml`: nessuna sanitizzazione Angular (core-libs/storefront/cms-components/content/paragraph/paragraph.component.html:L1-L4, core-libs/storefront/cms-components/content/paragraph/paragraph.component.ts:L49-L51). Un `@HostListener('click')` intercetta i click su `<a>`: se l'host coincide con quello del documento fa `preventDefault` e `router.navigateByUrl` (navigazione SPA) (core-libs/storefront/cms-components/content/paragraph/paragraph.component.ts:L29-L42). La pipe riscrive gli `href="#id"` prefissandoli con l'URL corrente senza fragment, usando un `<template>` creato via `Renderer2` (core-libs/storefront/shared/pipes/suplement-hash-anchors/supplement-hash-anchors.pipe.ts:L10-L50).
- **Link.** `LinkComponent` si sottoscrive a mano in `ngOnInit` per `styleClasses` e si disiscrive in `ngOnDestroy`; il template delega a `cx-generic-link` con `url`, `style` e `target` (core-libs/storefront/cms-components/content/link/link.component.ts:L35-L53, core-libs/storefront/cms-components/content/link/link.component.html:L1-L7).
- **BannerCarousel.** `data.banners` è una stringa di uid separati da spazi: viene splittata e ogni uid diventa un Observable `cmsService.getComponentData(code)`; la classe host è `${effect}-theme` (core-libs/storefront/cms-components/content/banner-carousel/banner-carousel.component.ts:L30-L47). Ogni item è reso con `[cxComponentWrapper]` dentro `cx-carousel` con `itemWidth="100%"` (core-libs/storefront/cms-

components/content/banner-carousel/banner-carousel.component.html:L1-L17): un componente CMS che istanzia altri componenti CMS.

- **PDF.** `url = MediaService.getMedia(data.pdfFile)?.src`; `addPdfExtension` aggiunge `.pdf` al titolo se manca (core-libs/storefront/cms-components/content/pdf/pdf.component.ts:L22-L43).
- **Video.** Flag stringa convertiti (`autoPlay`/`loop` → `=== 'true'`, `mute` → `'muted'|undefined`) (core-libs/storefront/cms-components/content/video/video.component.ts:L92-L96); thumbnail scelto in base a `containerBackground`/`thumbnailSelector` (core-libs/storefront/cms-components/content/video/video.component.ts:L67-L90); la cascata di routing replica quella del banner ma chiama `cd.markForCheck()` dopo la risoluzione asincrona della content page (core-libs/storefront/cms-components/content/video/video.component.ts:L98-L123).

3.4 Content: TabParagraphContainer e `cx-tab`

1. Config di default `{ openTabs: [0], breakpoint: BREAKPOINT.md }` (core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L39-L42).
2. `components$` splitta `data.components`, carica ogni figlio con `cmsService.getComponentData`, usa `typeCode` come `flexType` se mancante, imposta `title = ${containerUid}.tabs.${tabUid}` (chiave i18n), scarta i nulli ed emette su `tabConfig$` la label `${uid}.tabPanelContainerRegionGroup` (core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L99-L140).
3. Il template crea un `ng-template #tabRef` per figlio con `[cxOutlet]="component?.flexType" + [cxComponentWrapper]` e ascolta `(cxComponentRef)` (core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.html:L1-L15).
4. In `ngAfterViewInit` `tabs$` combina `components$`, `tabRefs.changes` e `tabTitleParams$` per produrre i `Tab` (`headerKey`, `content` = TemplateRef, `id`, `headerParams`), poi `cdr.detectChanges()` (core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L169-L200).
5. Quando un figlio viene creato, `tabCompLoaded` registra il suo `tabTitleParam$` una sola volta per uid, per evitare il loop `tabs$ → load → tabTitleParams$ → tabs$` (core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L202-L213).
6. `cx-tab` decide la modalità: `config.mode` se presente, altrimenti `TAB` sopra il breakpoint e `ACCORDIAN` sotto (`BreakpointService.isUp`), altrimenti `TAB` (core-libs/storefront/cms-components/content/tab/tab.component.ts:L254-L268). In `TAB` `select()` apre solo il tab scelto, in `ACCORDIAN` fa toggle (core-libs/storefront/cms-components/content/tab/tab.component.ts:L96-L105, core-libs/storefront/cms-components/content/tab/tab.component.ts:L196-L205).
7. Tastiera: frecce, Home ed End spostano solo il focus con wrap circolare (`wrapIntoBounds`); `restrictDirectionKeys` limita Tab a ←/→ e Accordion a ↑/↓ (core-libs/storefront/cms-components/content/tab/tab.component.ts:L136-L182, core-libs/storefront/cms-components/content/tab/tab.utils.ts:L12-L20). ARIA: `role="tab"` in modalità TAB, `role="button"` + `aria-expanded` in ACCORDIAN (core-libs/storefront/cms-components/content/tab/tab.component.html:L4-L17).

3.5 Navigation: dall'entry CMS al menu

1. `NavigationComponent.node$ = service.createNavigation(componentData.data$)` (core-libs/storefront/cms-components/navigation/navigation/navigation.component.ts:L23-L40). `createNavigation` incapsula il nodo radice in `{ title: data.name, children: [nav] }` (core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L27-L38). `CategoryNavigationComponent` e `FooterNavigationComponent` usano invece `getNavigationNode` direttamente, **senza** nodo wrapper (core-libs/storefront/cms-components/navigation/category-navigation/category-navigation.component.ts:L22-L33, core-libs/storefront/cms-components/navigation/footer-navigation/footer-navigation.component.ts:L23-L26).

2. `getNavigationNode` prende `data.navigationNode ?? data` e legge gli entry item dallo store con `cmsService.getNavigationEntryItems(uid)` (un `select` NgRx) (core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L45-L57, core-libs/core/src/cms/facade/cms.service.ts:L171-L192).
3. Se gli item sono `undefined`, `loadNavigationEntryItems(navigation, true)` raccoglie ricorsivamente `{superType, id}` di entries e children e dispatcha **solo per la radice** (core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L95-L118); `CmsService.loadNavigationItems` dispatcha `CmsActions.LoadCmsNavigationItems` (core-libs/core/src/cms/facade/cms.service.ts:L171-L192).
4. Se gli item ci sono ma ne mancano alcuni, carica solo i mancanti (core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L63-L80).
5. `filter(Boolean)` e poi `populateNavigationNode` ricorsivo: titolo, `styleClasses`, `styleAttributes`, link dalla **prima** entry, figli filtrati; un nodo senza proprietà diventa `null` e viene scartato (core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L125-L161).
6. `populateLink` considera solo `itemType === 'CMSLinkComponent'`, cerca l'item con chiave `${itemId}_${itemSuperType}` e imposta `url` solo se il nodo ha un titolo; `target='_blank'` se `item.target` è `'true'`/`true` (core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L166-L193). `getLink` (protected) sceglie `url` → `contentPageLabelOrId` → route `category` → route `product` (core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L201-L223).
7. `cx-navigation-ui` rende l'albero. Input: `node`, `wrapAfter`, `resetMenuOnClose`, `focusableNodeTitles`, `navAriaLabel`, `flyout` (default `true`, classe host `flyout`), `isOpen` (classe host `is-open`) (core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L57-L88). La category navigation passa `wrapAfter` convertito con `+`, `resetMenuOnClose` e l'aria-label `navigation.categoryNavLabel` (core-libs/storefront/cms-components/navigation/category-navigation/category-navigation.component.html:L1-L8); il footer disattiva il flyout (core-libs/storefront/cms-components/navigation/footer-navigation/footer-navigation.component.html:L1-L7).
8. Apertura sottomenu: `toggleOpen` gestisce click e tastiera; con `a11yNavigationSpaceKeyOnKeyUp` ignora `keydown` e reagisce su `keyup`, altrimenti il contrario (core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L197-L229, core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1093-L1093). Lo stato vive in `openNodes: HTMLElement[]` ed è riflesso con `Renderer2` come `is-open` (ultimo) e `is-opened` (antenati) (core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L381-L393).
9. A ogni `NavigationEnd` il costruttore chiama `clear()`, che azzera `openNodes` e la classe host `is-open` (core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L118-L122, core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L303-L306, core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L381-L393): le classi `is-open`/`is-opened` già applicate ai `<li>` e gli `aria-expanded` restano, li rimuove solo `reinitializeMenu()` (core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L166-L185). Su `window:resize` con `debounceTime(50)` riallinea i `.wrapper` che sbordano a destra (core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L95-L128, core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L356-L372).
10. Con `resetMenuOnClose` il componente si sottoscrive a `HamburgerMenuService.isExpanded` e reinizializza il menu quando l'hamburger si apre (core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L133-L185). Il numero di colonne di un sottomenu è 1 senza `wrapAfter` (o con `length <= 0`); altrimenti `floor(length / wrapAfter)`, più 1 se c'è resto e il quoziente è almeno 1, quindi con meno figli di `wrapAfter` il risultato è 0, non 1 (core-libs/storefront/cms-components/

navigation/navigation/navigation-ui.component.ts:L323-L335); getTabIndex dà -1 alle foglie in profondità > 0 solo con flyout (core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L398-L403).

3.6 Navigation: breadcrumb, titolo, scroll-to-top, search box

- **Breadcrumb** estende PageTitleComponent; le crumb vengono da pageMetaService.getMeta().breadcrumbs, con fallback [{ label: 'common.home' tradotto, link: '/' }] (core-libs/storefront/cms-components/navigation/breadcrumb/breadcrumb.component.ts:L32-L66). ariaLive$ emette a ogni NavigationEnd il booleano document.activeElement !== document.body (core-libs/storefront/cms-components/navigation/breadcrumb/breadcrumb.component.ts:L37-L42). I meta di pagina sono descritti nel capitolo 40.
- **Page title**: getPageTitle restituisce meta.heading || meta.title (core-libs/storefront/cms-components/navigation/page-header/page-title.utils.ts:L11-L18, core-libs/storefront/cms-components/navigation/page-header/page-title.component.ts:L25-L45).
- **Scroll-to-top**: scrollBehavior e displayThreshold dai dati CMS con take(1); default SMOOTH e metà di innerHeight (400/2 se assente) (core-libs/storefront/cms-components/navigation/scroll-to-top/scroll-to-top.component.ts:L40-L42, core-libs/storefront/cms-components/navigation/scroll-to-top/scroll-to-top.component.ts:L102-L107). Visibile se scrollY > displayThreshold o se attivato da tastiera e ancora focalizzato (core-libs/storefront/cms-components/navigation/scroll-to-top/scroll-to-top.component.ts:L66-L123).
- **Search box**: config di default (minCharactersBeforeRequest: 1, max 5 prodotti/suggerimenti, recent e trending attivi) (core-libs/storefront/cms-components/navigation/search-box/search-box.component.ts:L61-L72) fusa a tre livelli default → dati CMS → @Input() config, con conversione dei flag stringa 'false' e riscrittura del risultato in this.config (core-libs/storefront/cms-components/navigation/search-box/search-box.component.ts:L246-L266). SearchBoxComponentService.search non chiama il backend sotto minCharactersBeforeRequest e usa searchWithCompletion/searchSuggestionsWithCompletion con pageSize = maxProducts/maxSuggestions (core-libs/storefront/cms-components/navigation/search-box/search-box-component.service.ts:L70-L125); getResults toggla sul body la classe has-searchbox-results (core-libs/storefront/cms-components/navigation/search-box/search-box-component.service.ts:L149-L166). Eventi SearchBoxSuggestionSelectedEvent/SearchBoxProductSelectedEvent via EventService (core-libs/storefront/cms-components/navigation/search-box/search-box.events.ts:L12-L32, core-libs/storefront/cms-components/navigation/search-box/search-box-component.service.ts:L204-L230) e tre outlet SearchBoxOutlets (core-libs/storefront/cms-components/navigation/search-box/search-box-outlets.model.ts:L7-L11). La ricerca prodotti lato core è nel capitolo 24. DA VERIFICARE: la logica interna di recent/trending searches e della gestione focus a gruppi di SearchBoxComponent (951 righe) è stata solo mappata dall'analista, non letta per intero.

3.7 Misc: Icon (rappresentativo), site context, theme, messaggi

1. IconComponent ha selettore doppio cx-icon,[cxIcon]: come attributo non aggiunge un nodo DOM e il contenuto è proiettato (core-libs/storefront/cms-components/misc/icon/icon.component.ts:L22-L46).
2. I setter cxIcon e type chiamano setIcon, che ottiene l'HTML dal loader, aggiunge le classi, carica l'eventuale risorsa LINK e imposta il flip (core-libs/storefront/cms-components/misc/icon/icon.component.ts:L52-L99). addStyleClasses aggiunge sempre cx-icon, rimuove le classi del tipo precedente e aggiunge quelle del simbolo split per spazio (core-libs/storefront/cms-components/misc/icon/icon.component.ts:L113-L126).
3. IconLoaderService.getHtml: per SVG costruisce <svg><use xlink:href> con URL sanitizzato (SecurityContext.URL); per TEXT mette il simbolo in textContent; per i font (LINK) restituisce undefined e bastano le classi (core-libs/storefront/cms-components/misc/icon/icon-loader.service.ts:L33-L55). Il

template rende `<i [outerHTML]="icon">` solo se c'è HTML e proietta `<ng-content />` (core-libs/storefront/cms-components/misc/icon/icon.component.html:L1-L4).

4. `addLinkResource` inietta una sola volta per URL un `<link rel="stylesheet">` nel `<head>`, cercando una risorsa specifica per tipo o una "one-size-fits-all" senza `types` (core-libs/storefront/cms-components/misc/icon/icon-loader.service.ts:L118-L160).
5. Configurazione: `IconConfig` è una classe astratta `useExisting: Config` con `IconOptions` (`symbols`, `resources`, `flipDirection`) (core-libs/storefront/cms-components/misc/icon/icon.model.ts:L79-L121); `IconResourceType` vale `SVG`, `LINK`, `TEXT` (core-libs/storefront/cms-components/misc/icon/icon.model.ts:L133-L149). `IconModule` fornisce `defaultIconConfig` (flip RTL dei caret) e `fontawesomeIconConfig` (core-libs/storefront/cms-components/misc/icon/icon.module.ts:L14-L23, core-libs/storefront/cms-components/misc/icon/default-icon.config.ts:L10-L17); quest'ultimo mappa ogni `ICON_TYPE` su classi Font Awesome con una risorsa LINK a `url: ''`, quindi nessun CSS viene caricato dinamicamente (core-libs/storefront/cms-components/misc/icon/fontawesome-icon.config.ts:L9-L86). `ICON_TYPE` è un enum augmentabile riesportato nel blocco delimitato dal commento `AUGMENTABLE_TYPES_START` (core-libs/storefront/cms-components/misc/icon/icon.model.ts:L11-L77, core-libs/storefront/public_api.ts:L32-L36).
6. **Site context selector.** `SiteContextComponentService` risolve il contesto dall'`@Input context` o da `componentData.data$.context` (LANGUAGE/CURRENCY → id di contesto) (core-libs/storefront/cms-components/misc/site-context-selector/site-context-component.service.ts:L91-L118), poi trova il service concreto con `injector.get(contextServiceMap[context])` (core-libs/storefront/cms-components/misc/site-context-selector/site-context-component.service.ts:L120-L125). Label: `nativeName` per la lingua, `symbol + ' ' + isocode` per la valuta (core-libs/storefront/cms-components/misc/site-context-selector/site-context-component.service.ts:L127-L136). Il `<select>` appare solo con più di un item e il `change` passa dal setter `active` (core-libs/storefront/cms-components/misc/site-context-selector/site-context-selector.component.html:L1-L4, core-libs/storefront/cms-components/misc/site-context-selector/site-context-selector.component.ts:L68-L70). `LanguageCurrencyComponent` affianca due selettori in un template inline (core-libs/storefront/cms-components/misc/site-context-selector/language-currency.component.ts:L11-L22). Il meccanismo dei contesti è nel capitolo 13.
7. **Theme switcher**: delega a `SiteThemeService` tramite `SiteThemeSwitcherComponentService`, fornito dal modulo e non root (core-libs/storefront/cms-components/misc/site-theme-switcher/site-theme-switcher.module.ts:L28-L36, core-libs/storefront/cms-components/misc/site-theme-switcher/site-theme-switcher.component.service.ts:L11-L26).
8. **Messaggi**: `GlobalMessageComponent` legge `globalMessageService.get()` e rimuove con `remove(type, index)` (core-libs/storefront/cms-components/misc/global-message/global-message.component.ts:L33-L51); `MessageComponent` mappa `GlobalMessageType` su classi e icone e focalizza il contenitore se ha testo accordion o bottone d'azione (core-libs/storefront/cms-components/misc/message/message.component.ts:L62-L89). Il servizio dei global message è nel capitolo 41.

3.8 Shared: Media

1. `cx-media` accetta `MediaContainer | Image | ImageGroup | ImageGroup[]`; con un array usa solo il primo elemento (core-libs/storefront/shared/components/media/media.component.ts:L62-L67, core-libs/storefront/shared/components/media/media.component.ts:L162-L174).
2. A ogni `ngOnChanges` ricalcola il `Media`; senza `src` entra in stato "missing" (`is-missing`, `is-initialized`) ed emette `loaded(false)` (core-libs/storefront/shared/components/media/media.component.ts:L155-L208). Le classi host `is-initialized`, `is-loading`, `is-missing` sono aggiornate da `loadHandler` sull'evento `(load)` (core-libs/storefront/shared/components/media/media.component.ts:L134-L148, core-libs/storefront/shared/components/media/media.component.ts:L179-L184).

3. `fetchPriority === HIGH` forza `loading="eager"`, altrimenti vale `loading` o la strategia globale (core-libs/storefront/shared/components/media/media.component.ts:L217-L222), che per default è `LAZY` (core-libs/storefront/shared/components/media/media.service.ts:L163-L168).
4. Template: `<picture>` con `<source>` se `elementType !== 'img'` e ci sono `sources`, altrimenti `<img>` con `srcset` (fallback `src`) e `sizes` (core-libs/storefront/shared/components/media/media.component.html:L1-L47).
5. `MediaService`: `sortedFormats` ordina `mediaFormats` per larghezza e lo memorizza (core-libs/storefront/shared/components/media/media.service.ts:L175-L190); `resolveFormat` usa il formato richiesto, poi il più grande disponibile, poi la prima chiave (core-libs/storefront/shared/components/media/media.service.ts:L255-L276); `resolveSrcSet` produce `"url widthw, ..."` (core-libs/storefront/shared/components/media/media.service.ts:L285-L309); i formati `<picture>` derivano da `media.pictureElementFormats` ordinati con `media.pictureFormatsOrder` (core-libs/storefront/shared/components/media/media.service.ts:L197-L231).
6. URL assoluti: `resolveAbsoluteUrl` lascia stare `http…` e `//…`, gli altri li prefissa con `getBaseUrl()` (core-libs/storefront/shared/components/media/media.service.ts:L383-L387), che usa `backend.media.baseUrl ?? backend.occ.baseUrl ?? ''` e, con `enableMediaPrefix` (default `true`), compone `new URL(backend.media.prefix, baseUrl)` con fallback e log in caso di errore (core-libs/storefront/shared/components/media/media.service.ts:L399-L428, core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1032-L1032).
7. `MediaModule.forRoot()` registra un `APP_INITIALIZER` che aggiunge il link `preconnect` ed è importato da `BaseStorefrontModule` (core-libs/storefront/shared/components/media/media.module.ts:L14-L43, core-libs/storefront/base-storefront.module.ts:L42-L42).

3.9 Shared: Carousel, GenericLink, ItemCounter, FormErrors

- **Carousel.** Disattiva l'hydration con `host: { ngSkipHydration: 'true' }` (core-libs/storefront/shared/components/carousel/carousel.component.ts:L57-L65). Gli item sono Observable (caricamento lazy); cambiare `items` riporta `activeSlide` a 0 (core-libs/storefront/shared/components/carousel/carousel.component.ts:L89-L95). `template` è obbligatorio, `itemWidth` vale `'300px'` di default (core-libs/storefront/shared/components/carousel/carousel.component.ts:L101-L153). `CarouselService.getItemsPerSlide` ricalcola su `WindowRef.resize$` gli item per slide da `clientWidth` e `itemWidth` in px o % (core-libs/storefront/shared/components/carousel/carousel.service.ts:L29-L60, core-libs/core/src/window/window-ref.ts:L91-L107). Il template raggruppa gli item in `div.slide` (core-libs/storefront/shared/components/carousel/carousel.component.html:L39-L72); le frecce ←/→ spostano il focus tra `[cxFocusableCarouselItem]` cambiando slide (core-libs/storefront/shared/components/carousel/carousel.component.ts:L210-L287).
- **GenericLink.** `[href]` per URL esterni, `[routerLink]` + `queryParams` + `fragment` per quelli locali (core-libs/storefront/shared/components/generic-link/generic-link.component.html:L3-L38). Esterno = stringa che inizia con `http://`, `https://`, `mailto:` o `tel:` (core-libs/storefront/shared/components/generic-link/generic-link-component.service.ts:L12-L39). Per URL locali aggiunge lo slash iniziale e separa path/query/fragment (core-libs/storefront/shared/components/generic-link/generic-link.component.ts:L43-L127); `rel="noopener"` solo per i link esterni e solo con `target === '_blank'`; il ramo `routerLink` non imposta `rel` (core-libs/storefront/shared/components/generic-link/generic-link.component.ts:L65-L67, core-libs/storefront/shared/components/generic-link/generic-link.component.html:L3-L7, core-libs/storefront/shared/components/generic-link/generic-link.component.html:L19-L24).
- **ItemCounter.** Lavora su un `UntypedFormControl` del parent; input `min` (1), `max`, `step` (1), `allowZero`, `readonly` (core-libs/storefront/shared/components/item-counter/item-counter.component.ts:L42-L86). In `ngOnInit` corregge ogni valore entro `[min,max]` con `emitEvent: false` (core-libs/storefront/shared/

components/item-counter/item-counter.component.ts:L95-L146). I bottoni usano aria-disabled (core-libs/storefront/shared/components/item-counter/item-counter.component.html:L1-L54).

- **FormErrors.** errorsDetails$ nasce da control.statusChanges (core-libs/storefront/shared/components/form/form-errors/form-errors.component.ts:L73-L88); la chiave di traduzione è un array [prefix.key, fallbackPrefix.key], accettato da TranslatePipe (core-libs/storefront/shared/components/form/form-errors/form-errors.component.html:L1-L10, core-libs/core/src/i18n/translate.pipe.ts:L42-L43); il componente è cx-visually-hidden finché il controllo non è invalid e touched/dirty, con aria-live di default polite (core-libs/storefront/shared/components/form/form-errors/form-errors.component.ts:L126-L142). Poiché il cambio di touched non emette eventi, ngDoCheck lo confronta a mano (core-libs/storefront/shared/components/form/form-errors/form-errors.component.ts:L96-L112).

3.10 Shared: Popover, Pagination, direttive

- **Popover.** [cxPopover] accetta stringa o TemplateRef (core-libs/storefront/shared/components/popover/popover.directive.ts:L32-L52). Tutti gli eventi passano da un unico eventSubject smistato in handlePopoverEvents (core-libs/storefront/shared/components/popover/popover.directive.ts:L117-L182). renderPopover crea PopoverComponent con ComponentFactoryResolver (deprecato in Angular, angular:packages/core/src/linker/component_factory_resolver.ts:L38-L41) e, con appendToBody, sposta il nodo nel primo elemento figlio del body (body.firstElementChild ?? body, di solito il root dell'app) (core-libs/storefront/shared/components/popover/popover.directive.ts:L187-L221, core-libs/storefront/shared/components/popover/popover.directive.ts:L210-L217). PopoverComponent si riposiziona su resize, opzionalmente su scroll e a ogni ngAfterViewChecked, e chiude su NavigationStart (core-libs/storefront/shared/components/popover/popover.component.ts:L211-L267); la posizione è calcolata da PositioningService.positionElements, che con auto prova 12 posizioni (core-libs/storefront/shared/services/positioning/positioning.service.ts:L285-L336).
- **Pagination.** PaginationBuilder.paginate non produce nulla con meno di 2 pagine e compone pagine → dots → first/last → navigazione (core-libs/storefront/shared/components/list-navigation/pagination/pagination.builder.ts:L65-L76); getStartOfRange centra la pagina corrente (core-libs/storefront/shared/components/list-navigation/pagination/pagination.builder.ts:L331-L346). PaginationComponent.getQueryParams imposta il query param e lo rimuove se uguale a defaultPage (core-libs/storefront/shared/components/list-navigation/pagination/pagination.component.ts:L199-L219). Con a11yPaginationKeyboardNavigation (default false) i link sono avvolti in uno span con cxRovingTabindex (core-libs/storefront/shared/components/list-navigation/pagination/pagination.component.html:L1-L38, core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1116-L1116).
- **Roving tabindex.** CxRovingTabindexDirective implementa il pattern APG (un solo item con tabindex 0, frecce, Home/End) (core-libs/storefront/shared/directives/roving-tabindex/roving-tabindex.directive.ts:L19-L181) e osserva solo childList con un MutationObserver creato solo se esiste (SSR) (core-libs/storefront/shared/directives/roving-tabindex/roving-tabindex.directive.ts:L121-L138). Per il quadro generale dell'accessibilità vedi il capitolo 18.
- **Horizontal scrolling position**: espone isScrollStart$, isScrollEnd$, isScrollNeeded$ (core-libs/storefront/shared/directives/horizontal-scrolling-position/horizontal-scrolling-position.directive.ts:L94-L116) calcolati con ResizeObserver/IntersectionObserver (core-libs/storefront/shared/directives/horizontal-scrolling-position/horizontal-scrolling-position.directive.ts:L199-L244) e non fa nulla fuori dal browser (core-libs/storefront/shared/directives/horizontal-scrolling-position/horizontal-scrolling-position.directive.ts:L122-L125).

3.11 Shared: servizi file, validator, config

- `FileDownloadService.download` crea, clicca e rimuove un `<a download>` (core-libs/storefront/shared/services/file/file-download.service.ts:L20-L29); `ExportCsvFileService.convert` quota solo le celle con il separatore e chiude le righe con `\r\n` (core-libs/storefront/shared/services/file/csv/export-csv-file.service.ts:L23-L52); `ImportCsvFileService` fa `split('\n')` + `split(separator)` (core-libs/storefront/shared/services/file/csv/import-csv-file.service.ts:L82-L88); `FilesFormValidators` offre `maxSize`, `maxEntries`, `allowedTypes` (core-libs/storefront/shared/services/file/files-form-validators.ts:L13-L86).
- `CustomFormValidators` raccoglie validator statici e gli array `passwordValidators`/`securePasswordValidators` (core-libs/storefront/shared/utils/validators/custom-form-validators.ts:L26-L218); `controlsMustMatch` non tocca il secondo controllo se ha già altri errori (core-libs/storefront/shared/utils/validators/custom-form-validators.ts:L444-L463); `sortTitles` ordina per `titleScores` (core-libs/storefront/shared/utils/forms/title-utils.ts:L9-L27).
- `FormConfig` e `ViewConfig` sono config augmentate `useExisting: Config` (core-libs/storefront/shared/config/form-config.ts:L10-L22, core-libs/storefront/shared/config/view-config.ts:L10-L30); `defaultFormConfig` è fornito da `PasswordVisibilityToggleModule` (core-libs/storefront/shared/config/default-form-config.ts:L9-L13, core-libs/storefront/shared/components/form/password-visibility-toggle/password-visibility-toggle.module.ts:L23-L23). `CaptchaModule` fornisce di default un renderer mock (core-libs/storefront/shared/components/captcha/captcha.module.ts:L15-L25); `TableModule` fornisce i componenti header/cella globali (core-libs/storefront/shared/components/table/table.module.ts:L28-L28, core-libs/storefront/shared/components/table/config/default-table.config.ts:L11-L16).

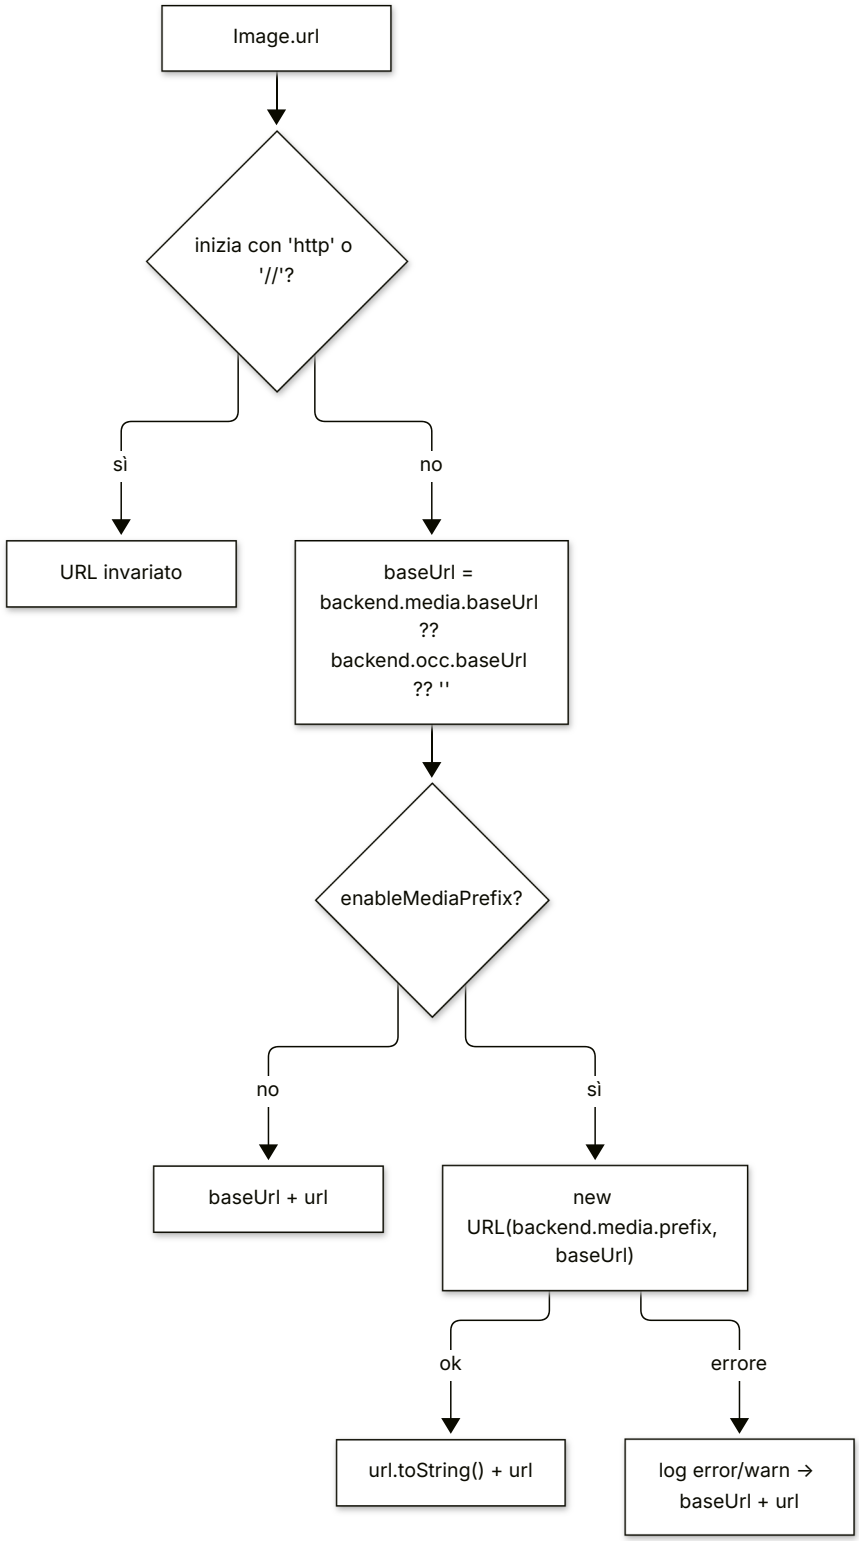
4.4 Risoluzione dell'URL di un'immagine



5. Estratti di codice reale

5.1 Il modulo wrapper del banner

core-libs/storefront/cms-components/content/banner/banner.module.ts:L20-L47

```ts
@NgModule({
  imports: [
    CommonModule,
    RouterModule,
    GenericLinkModule,
    MediaModule,
    FeaturesConfigModule,
    LcpContextDirectiveModule,
    BannerComponent,
  ],
  providers: [
    provideDefaultConfig(<CmsConfig>{
      cmsComponents: {
        SimpleResponsiveBannerComponent: {
          component: BannerComponent,
        },
        BannerComponent: {
          component: BannerComponent,
        },
        SimpleBannerComponent: {
          component: BannerComponent,
        },
      },
    }),
  ],
  exports: [BannerComponent],
})
export class BannerModule {}
```

5.2 Injector per istanza e merge dei dati statici

core-libs/storefront/cms-structure/page/component/services/cms-injector.service.ts:L28-L50

```ts
  public getInjector(
    type: string,
    uid: string,
    parentInjector?: Injector
  ): Injector {
    const configProviders =
      this.cmsComponentsService.getMapping(type)?.providers ?? [];
    return Injector.create({
```

```
    providers: [
      {
        provide: CmsComponentData,
        useFactory: (dataProvider: ComponentDataProvider) => ({
          uid,
          data$: dataProvider.get(uid, type),
        }),
        deps: [ComponentDataProvider],
      },
      provideLcpPresenceForCmsComponent(),
      ...configProviders,
    ],
    parent: parentInjector ?? this.injector,
  });
}
```

core-libs/storefront/cms-structure/page/component/services/component-data.provider.ts:L35-L59

```ts
get<T extends CmsComponent>(uid: string, type?: string): Observable<T> {
  return defer(() => {
    let staticComponentData: T | undefined;

    if (type) {
      staticComponentData = this.componentsService.getStaticData<T>(type);
    }

    if (uid) {
      if (staticComponentData) {
        return this.cmsService.getComponentData<T>(uid).pipe(
          map((data) => ({
            ...staticComponentData,
            ...data,
          })),
          startWith(staticComponentData)
        );
      } else {
        return this.cmsService.getComponentData<T>(uid);
      }
    } else {
      return staticComponentData ? of(staticComponentData) : EMPTY;
    }
  });
}
```

5.3 Banner: `data$` e cascata del link

core-libs/storefront/cms-components/content/banner/banner.component.ts:L44-L57

```ts
export class BannerComponent {
  routerLink: string | any[] | undefined;

  @HostBinding('class') styleClasses: string | undefined;

  private featureToggles = inject(FeatureToggles);
  protected el = inject(ElementRef);

  data$: Observable<CmsBannerComponent> = this.component.data$.pipe(
    tap((data) => {
      this.setRouterLink(data);
      this.styleClasses = data.styleClasses;
    })
  );
```

core-libs/storefront/cms-components/content/banner/banner.component.ts:L137-L161

```ts
  protected setRouterLink(data: CmsBannerComponent): void {
    if (data.urlLink) {
      this.routerLink = data.urlLink;
    } else if (data.contentPage) {
      this.cmsService
        .getPage({
          id: data.contentPage,
          type: PageType.CONTENT_PAGE,
        })
        .pipe(take(1))
        .subscribe((page) => {
          this.routerLink = page?.label;
        });
    } else if (data.product) {
      this.routerLink = this.urlService.transform({
        cxRoute: 'product',
        params: { code: data.product },
      });
    } else if (data.category) {
      this.routerLink = this.urlService.transform({
        cxRoute: 'category',
        params: { code: data.category },
      });
    }
  }
```

5.4 Paragraph: HTML fidato e click intercettati

core-libs/storefront/cms-components/content/paragraph/paragraph.component.html:L1-L4

```HTML
<div
  *ngIf="component.data$ | async as data"
  [innerHTML]="bypassSecurityTrustHtml(data.content | cxSupplementHashAnchors)"
></div>
```

core-libs/storefront/cms-components/content/paragraph/paragraph.component.ts:L29-L42

```TS
  @HostListener('click', ['$event'])
  public handleClick(event: Event): void {
    if (event.target instanceof HTMLAnchorElement) {
      const element = event.target as HTMLAnchorElement;
      const href = element?.getAttribute('href');
      const documentUrlObject = new URL(element.ownerDocument.URL);

      // Use router for internal link navigation
      if (href && documentUrlObject.host === element.host) {
        event.preventDefault();
        this.router.navigateByUrl(href.replace(documentUrlObject.origin, ''));
      }
    }
  }
```

5.5 TabParagraphContainer: dal campo `components` ai tab

core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L99-L140

```TS
  components$: Observable<any[]> = this.componentData.data$.pipe(
    distinctUntilChanged((x, y) => x?.components === y?.components),
    tap((data: CMSTabParagraphContainer) => {
      this.ariaLabel = `${data?.uid}.tabPanelContainerRegion`;
    }),
    switchMap((data) =>
      combineLatest(
        (data?.components ?? '').split(' ').map((component) =>
          this.cmsService.getComponentData<any>(component).pipe(
            distinctUntilChanged(),
            map((tab) => {
              if (!tab) {
                return undefined;
              }

              if (!tab.flexType) {
                tab = {
                  ...tab,
                  flexType: tab.typeCode,
                };
              }
```

```
            return {
              ...tab,
              title: `${data.uid}.tabs.${tab.uid}`,
            };
          })
        )
      )
    ).pipe(
      // Remove tabs whose component data is null or undefined
      map((tabs) => tabs.filter((tab) => tab != null)),
      // Update tablist label with name from CMS
      tap(() => {
        this.tabConfig$.next({
          label: `${data?.uid}.tabPanelContainerRegionGroup`,
          ...defaultTabConfig,
        });
      })
    )
  )
);
```

core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L202-L213

```ts
tabCompLoaded(componentRef: any, componentId?: string): void {
  this.tabTitleParams.push(componentRef.instance.tabTitleParam$);
  if (componentId) {
    const currentParams = this.tabTitleParams$.getValue();
    // We need to check if the componentId is already in the map
    // to avoid infinite loop(tabs$ emit -> component load -> tabTitleParams$ emit -> tabs$ emit)
    if (!currentParams.has(componentId)) {
      currentParams.set(componentId, componentRef.instance.tabTitleParam$);
      this.tabTitleParams$.next(currentParams);
    }
  }
}
```

core-libs/storefront/cms-components/content/tab/tab.component.ts:L254-L268

```ts
protected getMode(): Observable<TAB_MODE> {
  if (this.config.mode) {
    return of<TAB_MODE>(this.config.mode);
  }

  if (this.config.breakpoint) {
    return this.breakpointService
      .isUp(this.config.breakpoint)
```

```
        .pipe(
          map((isUp: boolean) => (isUp ? TAB_MODE.TAB : TAB_MODE.ACCORDIAN))
        );
    }

    return of<TAB_MODE>(TAB_MODE.TAB);
  }
```

5.6 NavigationService: caricamento incrementale e link

core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L51-L84

```ts
    return data$.pipe(
      filter((data) => !!data),
      switchMap((data) => {
        const navigation = data.navigationNode ? data.navigationNode : data;
        return this.cmsService
          .getNavigationEntryItems(navigation.uid ?? '')
          .pipe(
            tap((items) => {
              if (items === undefined) {
                this.loadNavigationEntryItems(navigation, true);
                return;
              }
              // we should check whether the existing node items are what expected
              const expectedItems: {
                superType: string | undefined;
                id: string | undefined;
              }[] = [];
              this.loadNavigationEntryItems(navigation, false, expectedItems);
              const existingItems = Object.keys(items).map(
                (key) => items[key].uid ?? ''
              );
              const missingItems = expectedItems.filter(
                (it) => it.id && !existingItems.includes(it.id)
              );
              if (missingItems.length > 0) {
                this.cmsService.loadNavigationItems(
                  navigation.uid ?? '',
                  missingItems
                );
              }
            }),
            filter(Boolean),
            map((items) => this.populateNavigationNode(navigation, items) ?? {})
          );
```

core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L166-L183

```ts
private populateLink(node: NavigationNode, entry: any, items: any) {
  const item = items[`${entry.itemId}_${entry.itemSuperType}`];

  // now we only consider CMSLinkComponent
  if (item && entry.itemType === 'CMSLinkComponent') {
    if (!node.title) {
      node.title = item.linkName;
    }
    const url = this.getLink(item);
    // only populate the node link if we have a visible node
    if (node.title && url) {
      node.url = url;
      // the backend provide boolean value for the target
      // in case the link should be opened in a new window
      if (item.target === 'true' || item.target === true) {
        node.target = '_blank';
      }
    }
```

5.7 NavigationUIComponent: tastiera dipendente dal feature toggle

core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L197-L229

```ts
toggleOpen(event: UIEvent): void {
  const isKeyboard = event.type === 'keydown' || event.type === 'keyup';
  if (this.featureToggles?.a11yNavigationSpaceKeyOnKeyUp) {
    if (event.type === 'keydown') {
      event.preventDefault();
      return;
    }
  } else if (event.type === 'keyup') {
    return;
  }
  if (isKeyboard) {
    event.preventDefault();
  }
  this.ariaCollapseNodes();
  const node = <HTMLElement>event.currentTarget;
  const parentNode = <HTMLElement>node.parentNode;
  if (this.openNodes.includes(parentNode)) {
    if (isKeyboard) {
      this.back();
    } else {
      this.openNodes = this.openNodes.filter((n) => n !== parentNode);
      this.renderer.removeClass(parentNode, 'is-open');
    }
  } else {
    this.openNodes.push(parentNode);
```

```
      this.renderer.setAttribute(node, ARIA_EXPANDED_ATTR, 'true');
    }

    this.updateClasses();

    event.stopImmediatePropagation();
    event.stopPropagation();
  }
```

5.8 Site context: provider per componente e risoluzione del service

core-libs/storefront/cms-components/misc/site-context-selector/site-context-selector.module.ts:L33-L52

```ts
  providers: [
    provideDefaultConfig(<CmsConfig>{
      cmsComponents: {
        CMSSiteContextComponent: {
          component: SiteContextSelectorComponent,
          providers: [
            {
              provide: SiteContextComponentService,
              useClass: SiteContextComponentService,
              deps: [CmsComponentData, ContextServiceMap, Injector],
            },
          ],
        },
        LanguageCurrencyComponent: {
          component: LanguageCurrencyComponent,
        },
      },
    }),
    SiteContextComponentService,
  ],
```

core-libs/storefront/cms-components/misc/site-context-selector/site-context-component.service.ts:L120-L125

```ts
  protected getInjectedService(context: string): SiteContext<any> {
    return this.injector.get<SiteContext<any>>(
      this.contextServiceMap[context],
      undefined
    );
  }
```

5.9 Icone: HTML sicuro e risorse LINK

core-libs/storefront/cms-components/misc/icon/icon.component.ts:L91-L99

```ts

    return;
  }
  this.icon = this.iconLoader.getHtml(type);
  this.addStyleClasses(type);
  this.iconLoader.addLinkResource(type);
  this.flipIcon(type);
}
```

core-libs/storefront/cms-components/misc/icon/icon-loader.service.ts:L33-L55

```ts
getHtml(type: ICON_TYPE | string): SafeHtml | undefined {
  if (this.isResourceType(type, IconResourceType.SVG)) {
    const url = this.sanitizer.sanitize(
      SecurityContext.URL,
      this.getSvgPath(type) || null
    );
    if (url) {
      const useElement = this.winRef.document.createElement('use');
      useElement.setAttribute('xlink:href', url);
      const svgElement = this.winRef.document.createElement('svg');
      svgElement.appendChild(useElement);
      return this.sanitizer.bypassSecurityTrustHtml(svgElement.outerHTML);
    }
  }
  if (this.isResourceType(type, IconResourceType.TEXT)) {
    const symbol = this.getSymbol(type);
    if (symbol) {
      const helperDiv = this.winRef.document.createElement('div');
      helperDiv.textContent = symbol;
      return this.sanitizer.bypassSecurityTrustHtml(helperDiv.innerHTML);
    }
  }
}
```

core-libs/storefront/cms-components/misc/icon/icon-loader.service.ts:L139-L160

```ts
private findResource(
  iconType: ICON_TYPE | string,
  resourceType: IconResourceType
): IconConfigResource | undefined {
  if (!this.config?.resources) {
    return;
  }

  let resource = this.config.resources.find(
    (res) =>
```

```
      res.type === resourceType && res.types && res.types.includes(iconType)
  );
  // no specific resource found, let's try to find a one-size-fits-all resource
  if (!resource) {
    resource = this.config.resources.find(
      (res) =>
        (res.type === resourceType && !res.types) ||
        (res.types && res.types.length === 0)
    );
  }
  return resource;
}
```

5.10 MediaService: base URL e srcset

core-libs/storefront/shared/components/media/media.service.ts:L399-L428

TS

```
public getBaseUrl(): string {
  const baseUrl =
    this.config.backend?.media?.baseUrl ??
    this.config.backend?.occ?.baseUrl ??
    '';

  if (!this.featureToggles.enableMediaPrefix) {
    return baseUrl;
  }

  try {
    const mediaPrefix = this.config?.backend?.media?.prefix ?? '';
    // Construct URL (with Validation)
    const url = new URL(mediaPrefix, baseUrl);
    return url.toString();
  } catch (error) {
    if (isDevMode()) {
      this.logger.error(
        'Invalid media/occ baseUrl and prefix configuration',
        error
      );
    } else {
      this.logger.warn(
        'Invalid media/occ baseUrl and prefix configuration',
        error
      );
    }
    return baseUrl;
  }
}
```

core-libs/storefront/shared/components/media/media.service.ts:L175-L190

```ts
protected get sortedFormats(): { code: string; size: MediaFormatSize }[] {
  const mediaFormats = this.config?.mediaFormats;

  if (!this._sortedFormats && mediaFormats) {
    this._sortedFormats = Object.keys(mediaFormats)
      .map((key) => ({
        code: key,
        size: mediaFormats[key],
      }))
      .sort((a, b) =>
        a.size.width && b.size.width && a.size.width > b.size.width ? 1 : -1
      );
  }

  return this._sortedFormats ?? [];
}
```

5.11 Carousel: item per slide

core-libs/storefront/shared/components/carousel/carousel.service.ts:L29-L60

```ts
getItemsPerSlide(
  nativeElement: HTMLElement,
  itemWidth: string
): Observable<number> {
  return this.winRef.resize$.pipe(
    map(() => (nativeElement as HTMLElement).clientWidth),
    map((totalWidth) => this.calculateItems(totalWidth, itemWidth))
  );
}

/**
 * Calculates the number of items per given hostSize.  calculated based on the given
 * intended size in pixels or percentages. The
 *
 * @param availableWidth The available width in pixels for the carousel items.
 * @param itemWidth The width per carousel item, in px or percentage.
 */
private calculateItems(availableWidth: number, itemWidth: string) {
  let calculatedItems = 0;
  if (itemWidth.endsWith('px')) {
    const num = itemWidth.substring(0, itemWidth.length - 2);
    calculatedItems = availableWidth / <number>(<any>num);
  }

  if (itemWidth.endsWith('%')) {
    const perc = itemWidth.substring(0, itemWidth.length - 1);
```

```
      calculatedItems =
        availableWidth / (availableWidth * (<number>(<any>perc) / 100));
    }

    return Math.floor(calculatedItems) || 1;
  }
```

5.12 GenericLink: cosa è "esterno"

core-libs/storefront/shared/components/generic-link/generic-link-component.service.ts:L12-L39

```ts
export class GenericLinkComponentService {
  /**
   * Pattern matching string starting with `http://` or `https://`.
   */
  protected HTTP_PROTOCOL_REGEX: RegExp = /^https?:\/\//i;

  /**
   * Pattern matching string starting with `mailto:`.
   */
  protected MAILTO_PROTOCOL_REGEX: RegExp = /^mailto:/i;

  /**
   * Pattern matching string starting with `tel:`.
   */
  protected TEL_PROTOCOL_REGEX: RegExp = /^tel:/i;

  /**
   * Returns true when the @Input `url` is a string starting with `http://`, `https://`, `mailto:`,
`tel:`.
   */
  isExternalUrl(url: string | any[]): boolean {
    return (
      typeof url === 'string' &&
      (this.HTTP_PROTOCOL_REGEX.test(url) ||
        this.MAILTO_PROTOCOL_REGEX.test(url) ||
        this.TEL_PROTOCOL_REGEX.test(url))
    );
  }
}
```

5.13 ItemCounter: clamp del valore

core-libs/storefront/shared/components/item-counter/item-counter.component.ts:L95-L101

```ts
ngOnInit() {
  this.sub = this.control.valueChanges
    .pipe(startWith(this.control.value))
    .subscribe((value) =>
      this.control.setValue(this.getValidCount(value), { emitEvent: false })
    );
}
```

core-libs/storefront/shared/components/item-counter/item-counter.component.ts:L138-L146

```ts
private getValidCount(value: number) {
  if (value < this.min && !(value === 0 && this.allowZero)) {
    value = this.min;
  }
  if (this.max && value > this.max) {
    value = this.max;
  }
  return value;
}
```

5.14 FormErrors: ngDoCheck e il workaround per `aria-live`

core-libs/storefront/shared/components/form/form-errors/form-errors.component.ts:L96-L112

```ts
ngDoCheck(): void {
  if (this.control.touched !== this.previousTouchedState) {
    if (
      this.elementRef?.nativeElement?.getAttribute('aria-live') === 'polite'
    ) {
      // due to the way we detect changes here, JAWS doesn't always respect
      // aria live `polite`, so we need to move this in the next event-loop queue
      setTimeout(() => {
        this.previousTouchedState = this.control.touched;
        this.ChangeDetectionRef.markForCheck();
      });
    } else {
      this.previousTouchedState = this.control.touched;
      this.ChangeDetectionRef.markForCheck();
    }
  }
}
```

5.15 SearchBox: merge a tre livelli

core-libs/storefront/cms-components/navigation/search-box/search-box.component.ts:L246-L266

```ts
  protected config$: Observable<SearchBoxConfig> = (
    this.componentData?.data$ || of({} as any)
  ).pipe(
    map((config) => {
      const isBool = (obj: SearchBoxConfig, prop: string): boolean =>
        obj[prop as keyof SearchBoxConfig] !== 'false' &&
        obj[prop as keyof SearchBoxConfig] !== false;

      return {
        ...DEFAULT_SEARCH_BOX_CONFIG,
        ...config,
        displayProducts: isBool(config, 'displayProducts'),
        displayProductImages: isBool(config, 'displayProductImages'),
        displaySuggestions: isBool(config, 'displaySuggestions'),
        // we're merging the (optional) input of this component, but write the merged
        // result back to the input property, as the view logic depends on it.
        ...this.config,
      };
    }),
    tap((config) => (this.config = config))
  );
```

5.16 Pagination: fallback e mutazione

core-libs/storefront/shared/components/list-navigation/pagination/pagination.builder.ts:L16-L23

```ts
const FALLBACK_PAGINATION_OPTIONS: PaginationOptions = {
  rangeCount: 3,
  dotsLabel: '...',
  startLabel: '«',
  previousLabel: '‹',
  nextLabel: '›',
  endLabel: '»',
};
```

core-libs/storefront/shared/components/list-navigation/pagination/pagination.builder.ts:L370-L375

```ts
  protected get config(): PaginationOptions {
    return Object.assign(
      FALLBACK_PAGINATION_OPTIONS,
      this.paginationConfig.pagination
    );
  }
```

5.17 Popover: FocusConfig solo con appendToBody

core-libs/storefront/shared/components/popover/popover.service.ts:L19-L32

```ts
getFocusConfig(event: PopoverEvent, appendToBody: boolean): FocusConfig {
  let config = {};

  if (event === PopoverEvent.OPEN_BY_KEYBOARD && appendToBody) {
    config = {
      trap: true,
      block: true,
      focusOnEscape: false,
      autofocus: true,
    };
  }

  return config;
}
```

`a11yBannerArrowKeyNavigation`	`false`	`core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1114-L1114`	frecce tra banner fratelli
`a11yPaginationKeyboardNavigation`	`false`	`core-libs/core/src/features-config/feature-toggles/config/feature-toggles.ts:L1116-L1116`	roving tabindex sulla paginazione

7. Commenti e note notevoli dal sorgente

- `// TODO: move the opinionated fontawesome config to a recipe` — la config Font Awesome vive ancora in `IconModule` (core-libs/storefront/cms-components/misc/icon/icon.module.ts:L18-L18). Se l'app non usa Font Awesome deve sovrascrivere `icon.symbols`/`icon.resources`.
- `NOTE: this is not working when the shadow is used as there's no head element available...` — `addLinkResource` non funziona dentro uno shadow DOM (core-libs/storefront/cms-components/misc/icon/icon-loader.service.ts:L114-L116).
- JSDoc del carousel: l'hydration è disattivata per differenze CSR/SSR (core-libs/storefront/shared/components/carousel/carousel.component.ts:L57-L59).
- `// DELIBERATELY PRIVATE PROPERTY, to remove easily in the future` sul campo `featureToggles` (core-libs/storefront/shared/components/carousel/carousel.component.ts:L136-L136, core-libs/storefront/cms-components/navigation/search-box/search-box-component.service.ts:L50-L50): non fateci affidamento in una sottoclasse.
- `// TODO: Improve a11y with better text appropriate to usage (example: loading cart spinner)` (core-libs/storefront/shared/components/spinner/spinner.component.ts:L10-L10).
- `// TODO: Insert mustEndWithLegalCharacter into this array when removing feature toogle: useEnhancedSecurePasswordValidators` (core-libs/storefront/shared/utils/validators/custom-form-validators.ts:L208-L208).
- `// CHECK SONAR` in fondo a `navigation.service.ts` (core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L226-L226).
- `// to avoid infinite loop(tabs$ emit -> component load -> tabTitleParams$ emit -> tabs$ emit)` in `tabCompLoaded` (core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L206-L207).
- `// Convert string value to number(prevents us from having '1' + 1 = '11' on increment)` in `updateValue` (core-libs/storefront/shared/components/item-counter/item-counter.component.ts:L114-L114).
- Il commento sul workaround di `aria-live` in `FormErrorsComponent.ngDoCheck` (estratto 5.14, core-libs/storefront/shared/components/form/form-errors/form-errors.component.ts:L101-L102).
- `@deprecated This method will be removed.` su `activeTabNum`, `ariaLabel`, `children`, `tabTitleParams`, `select()`, `ngOnInit()` di `TabParagraphContainerComponent` (core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L59-L80, core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L144-L167); `@deprecated since 2011.21 removed unused property` su `siteContextService` (core-libs/storefront/cms-components/misc/site-context-selector/site-context-selector.component.ts:L43-L46). Elenco completo nell'appendice A10.
- Commento esteso sul wrapper `span display:contents` per il roving tabindex nella paginazione (core-libs/storefront/shared/components/list-navigation/pagination/pagination.component.html:L3-L13) e JSDoc della classe `CxRovingTabindexDirective` su SSR, host tabella e gating via feature toggle a carico del chiamante (core-libs/storefront/shared/directives/roving-tabindex/roving-tabindex.directive.ts:L19-L54).
- `<!-- https://github.com/angular/angular/issues/24567 -->` in testa al template generic-link (core-libs/storefront/shared/components/generic-link/generic-link.component.html:L1-L1).
- JSDoc di `MediaComponent` sull'uso di più media query invece di `srcset` con densità nei `<source>` (core-libs/storefront/shared/components/media/media.component.ts:L27-L48).

8. Extension point

EXTENSION POINT	COME SI USA	DEFINIZIONE	RICETTA
Mapping `cmsComponents` (sostituire `component`, aggiungere `providers`, `data`)	`provideConfig(<CmsConfig>{ cmsComponents: { SimpleResponsiveBannerComponent: { component: MyBanner } } });` ordine e precedenza della config nel capitolo 11	core-libs/storefront/cms-components/content/banner/banner.module.ts:L31-L44	Ricette CMS, outlet e layout
Estendere un componente CMS (ereditarietà + `CmsComponentData`)	i componenti espongono metodi `protected` (es. `setRouterLink` del banner, `getLink` di `NavigationService`)	core-libs/storefront/cms-components/content/banner/banner.component.ts:L137-L161, core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L201-L223	Ricette CMS, outlet e layout
`providers` per componente (pattern site context)	fornire un service con `CmsComponentData` nelle deps solo per un typeCode	core-libs/storefront/cms-components/misc/site-context-selector/site-context-selector.module.ts:L36-L45	Ricette CMS, outlet e layout
`IconConfig` (`symbols`, `resources`, `flipDirection`) e `ICON_TYPE` augmentabile	sostituire Font Awesome con sprite SVG o testo	core-libs/storefront/cms-components/misc/icon/icon.model.ts:L11-L149	Ricette config/DI, Ricette stili
Override di service `providedIn: 'root'` (`IconLoaderService`, `NavigationService`, `SearchBoxComponentService`, `CarouselService`, `GenericLinkComponentService`, `MediaService`)	`{ provide: X, useClass: MyX };` molti metodi sono `protected` (`resolveFormat`, `resolveSrcSet`, `resolveAbsoluteUrl`, regex di `GenericLinkComponentService`)	core-libs/storefront/cms-components/misc/icon/icon-loader.service.ts:L33-L160, core-libs/storefront/shared/components/media/media.service.ts:L255-L428, core-libs/storefront/shared/components/generic-link/generic-link-component.service.ts:L12-L39	Ricette config/DI
`MediaConfig` (`mediaFormats`, `media.pictureElementFormats`, `media.pictureFormatsOrder`, `imageLoadingStrategy`)	config	core-libs/storefront/shared/components/media/media.config.ts:L19-L81	Ricette config/DI

EXTENSION POINT	COME SI USA	DEFINIZIONE	RICETTA
`PaginationConfig` / `PaginationBuilder` (step `protected`)	config o sottoclasse del builder	`core-libs/storefront/shared/components/list-navigation/pagination/config/pagination.config.ts:L11-L21`, `core-libs/storefront/shared/components/list-navigation/pagination/pagination.builder.ts:L65-L76`	Ricette config/DI
`SearchBoxConfig` (dati CMS o `@Input`) e `SearchBoxOutlets`	config per istanza o outlet per recent/trending searches	`core-libs/storefront/cms-components/navigation/search-box/search-box-outlets.model.ts:L7-L11`	Ricette CMS, outlet e layout
Eventi `SearchBoxSuggestionSelectedEvent`, `SearchBoxProductSelectedEvent`	`EventService.get(...)`	`core-libs/storefront/cms-components/navigation/search-box/search-box.events.ts:L12-L32`	Ricette config/DI (eventi)
`PopoverOptions`, `PopoverService`, `PositioningService`	opzioni della direttiva o override del service	`core-libs/storefront/shared/components/popover/popover.model.ts:L27-L84`, `core-libs/storefront/shared/services/positioning/positioning.service.ts:L285-L348`	Ricette config/DI
`FormConfig`, `ViewConfig`, `CaptchaApiConfig.captchaRenderer`, `TableConfig`	config	`core-libs/storefront/shared/config/form-config.ts:L10-L22`, `core-libs/storefront/shared/config/view-config.ts:L10-L30`, `core-libs/storefront/shared/components/captcha/captcha-api-config.ts:L11-L33`, `core-libs/storefront/shared/components/table/config/table.config.ts:L20-L43`	Ricette config/DI
`CustomFormValidators`, `controlsMustMatch`, `sortTitles`, pipe e direttive shared	riuso diretto nei propri componenti	`core-libs/storefront/shared/utils/validators/custom-form-validators.ts:L26-L463`	Ricette feature/checkout

EXTENSION POINT	COME SI USA	DEFINIZIONE	RICETTA
Traduzioni delle chiavi usate qui (`navigation.categoryNavLabel`, `formErrors.*`, `<uid>.tabs.<tabUid>`, `common.language`)	override delle risorse i18n (capitolo 37)	`core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L121-L124`	Ricette traduzioni
Testing: `IconTestingModule` (mock pubblico)	importarlo negli spec al posto di `IconModule`	`core-libs/storefront/cms-components/misc/icon/testing/icon-testing.module.ts:L10-L50`	Upgrade-safe

Cosa **non** è un extension point: `defaultIconConfig`, `tab.utils`, `defaultFormConfig` e `form-test-utils` non sono esportati dai rispettivi barrel (`core-libs/storefront/cms-components/misc/icon/index.ts:L7-L12`, `core-libs/storefront/cms-components/content/index.ts:L7-L25`, `core-libs/storefront/shared/config/index.ts:L7-L8`, `core-libs/storefront/shared/utils/index.ts:L7-L8`); importarli da path interni è l'anti-pattern descritto in Upgrade-safe. Il campo `featureToggles` di carousel e search box è dichiarato "deliberately private" (sezione 7). I barrel `generic-link/index.ts` e `popover/index.ts` riesportano invece tutti i file (`core-libs/storefront/shared/components/generic-link/index.ts:L7-L9`, `core-libs/storefront/shared/components/popover/index.ts:L7-L11`).

---

9. Trappole, casi limite, comportamenti controintuitivi

1. **HTML del paragrafo non sanitizzato.** `bypassSecurityTrustHtml` rende il contenuto CMS fidato per definizione: chi può scrivere in Backoffice può iniettare script (`core-libs/storefront/cms-components/content/paragraph/paragraph.component.ts:L49-L51`).
2. **Banner OnPush e link asincrono.** Con `contentPage`, `routerLink` è assegnato dentro una `subscribe` senza `markForCheck`; il video invece chiama `markForCheck` (`core-libs/storefront/cms-components/content/banner/banner.component.ts:L140-L149`, `core-libs/storefront/cms-components/content/video/video.component.ts:L107-L111`). `DA VERIFICARE` a runtime: se `getPage` emette in modo sincrono (pagina già in store) il problema non si manifesta; altrimenti il link appare solo al prossimo ciclo di change detection innescato da altro.
3. **Booleani stringa ovunque.** Il backend manda `'true'`/`'false'`: banner, navigation, video e search box convertono a mano (`core-libs/storefront/cms-components/content/banner/banner.component.ts:L133-L135`, `core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L180-L182`, `core-libs/storefront/cms-components/content/video/video.component.ts:L92-L96`, `core-libs/storefront/cms-components/navigation/search-box/search-box.component.ts:L250-L252`). Un componente custom che fa `if (data.flag)` sbaglia: `'false'` è truthy.
4. **Navigation: solo la prima entry, solo** `CMSLinkComponent`**.** Altri tipi di entry non generano link (`core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L166-L170`); un nodo senza titolo non riceve `url` anche se l'item ha un link (`core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L174-L177`).
5. `createNavigation` **vs** `getNavigationNode`**.** Il primo aggiunge un nodo radice con `title: data.name`; sostituire uno con l'altro in un componente custom sposta tutto di un livello (`core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L27-L38`).

6. **Accumulo di sottoscrizioni nella navigation UI.** `onSpace` chiama `setupArrowControls()` a ogni pressione e ogni chiamata aggiunge una nuova sottoscrizione a `arrowControls`; ↑/↓ sono ascoltati su `document` da *ogni* istanza di `cx-navigation-ui` (core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L100-L104, core-libs/storefront/cms-components/navigation/navigation/navigation-ui.component.ts:L256-L275).
7. **Testi hardcoded e config null in** `cx-tab`**.** `getTitle` concatena `'Collapse'`/`'Expand'` in inglese (core-libs/storefront/cms-components/content/tab/tab.component.ts:L239-L242); `handleKeydownEvent` e `getMode` accedono a `this.config.*` senza optional chaining, mentre `ngOnInit` usa `this.config?.openTabs` (core-libs/storefront/cms-components/content/tab/tab.component.ts:L66-L68, core-libs/storefront/cms-components/content/tab/tab.component.ts:L148-L151, core-libs/storefront/cms-components/content/tab/tab.component.ts:L255-L259).
8. `document` **globale.** Breadcrumb, scroll-to-top e `FileDownloadService` usano `document` invece di `WindowRef.document` (core-libs/storefront/cms-components/navigation/breadcrumb/breadcrumb.component.ts:L37-L42, core-libs/storefront/cms-components/navigation/scroll-to-top/scroll-to-top.component.ts:L85-L86, core-libs/storefront/shared/services/file/file-download.service.ts:L20-L29). DA VERIFICARE il comportamento in SSR: dipende da cosa espone l'ambiente `@angular/platform-server` come `document` globale.
9. `HighlightPipe` **senza match.** Solo con `caseSensitive = false`: se il termine non c'è, `textStartIndex` vale -1 e viene evidenziato un prefisso di `match.length - 1` caratteri; se il termine è lungo 1, `substring(0, 0)` vale `''` e `replaceAll('', ...)` inserisce uno span tra ogni carattere (core-libs/storefront/cms-components/navigation/search-box/highlight.pipe.ts:L15-L24). Con il default `true` la pipe usa `text.replace(match.trim(), ...)`, che senza match non evidenzia nulla; il search box usa il default e non è affetto (core-libs/storefront/cms-components/navigation/search-box/highlight.pipe.ts:L11-L29, core-libs/storefront/cms-components/navigation/search-box/search-box.component.html:L96-L96).
10. **Icone.** `fontawesomeIconConfig` contiene `PDF_FILE`, che non è nell'enum `ICON_TYPE` (core-libs/storefront/cms-components/misc/icon/fontawesome-icon.config.ts:L49-L49); alcuni simboli (`ARROW_RIGHT`/`ARROW_DOWN`/`ARROW_UP`) hanno doppio spazio e funzionano al primo render perché l'aggiunta delle classi salta le stringhe vuote (core-libs/storefront/cms-components/misc/icon/fontawesome-icon.config.ts:L72-L74, core-libs/storefront/cms-components/misc/icon/icon.component.ts:L121-L125). La rimozione no: cambiare `type` partendo da una di queste icone chiama `renderer.removeClass(host, '')` (core-libs/storefront/cms-components/misc/icon/icon.component.ts:L116-L118), cioè `el.classList.remove('')` (angular:packages/platform-browser/src/dom/dom_renderer.ts:L376-L378), che nel browser lancia una `DOMException` (SyntaxError) per token vuoto.
11. **Getter che creano Observable.** `SiteContextSelectorComponent` espone `items$`/`activeItem$` come getter e chiama `ariaLabel$()` nel template: a ogni ciclo di CD si creano nuovi Observable (core-libs/storefront/cms-components/misc/site-context-selector/site-context-selector.component.ts:L60-L82, core-libs/storefront/cms-components/misc/site-context-selector/site-context-selector.component.html:L1-L9).
12. `PaginationBuilder` **muta la costante di fallback.** `Object.assign(FALLBACK_PAGINATION_OPTIONS, ...)` scrive dentro l'oggetto di modulo condiviso (core-libs/storefront/shared/components/list-navigation/pagination/pagination.builder.ts:L370-L375). Inoltre il JSDoc di `addDots` dice "defaults to true" mentre il modello dice false e il codice esce se `!addDots` (core-libs/storefront/shared/components/list-navigation/pagination/pagination.builder.ts:L104-L115, core-libs/storefront/shared/components/list-navigation/pagination/pagination.model.ts:L59-L66); `PaginationComponent` usato standalone fuori da `PaginationModule` non riceve `defaultPaginationConfig` (core-libs/storefront/shared/components/list-navigation/pagination/pagination.module.ts:L28-L28).
13. **Media.** Con un array usa solo `container[0]` (core-libs/storefront/shared/components/media/media.component.ts:L165-L165); `sortedFormats` è memorizzato al primo accesso, quindi cambiare `mediaFormats` a runtime non ha effetto (core-libs/storefront/shared/components/media/media.service.ts:L178-L189);

`MediaSourcesPipe` è importato in `MediaModule` ma non usato nel template (core-libs/storefront/shared/components/media/media.module.ts:L20-L28); `loading` è inizializzato da un getter che usa `this.mediaService`, possibile solo perché `useDefineForClassFields` è `false` (core-libs/storefront/shared/components/media/media.component.ts:L89-L89, tsconfig.json:L799-L799).

14. **Carousel in SSR.** `WindowRef.resize$` emette `of(null)` sul server e `clientWidth` è 0: `calculateItems` restituisce 1 item per slide (anche con `%`, dove `0/0` dà `NaN || 1`) (core-libs/core/src/window/window-ref.ts:L97-L99, core-libs/storefront/shared/components/carousel/carousel.service.ts:L46-L60). È coerente con la scelta di saltare l'hydration (core-libs/storefront/shared/components/carousel/carousel.component.ts:L57-L65); vedi il capitolo 39.
15. **ItemCounter.** I bottoni usano `aria-disabled` e restano cliccabili: è la sottoscrizione `valueChanges` a riportare il valore nel range; il bottone + non toglie il tabindex a `value >= max` (core-libs/storefront/shared/components/item-counter/item-counter.component.html:L1-L54, core-libs/storefront/shared/components/item-counter/item-counter.component.ts:L95-L101).
16. **FormErrors senza control.** Il setter ignora `null`, ma `ngDoCheck` legge `this.control.touched` senza guard: se `control` non viene mai impostato si ha un errore (core-libs/storefront/shared/components/form/form-errors/form-errors.component.ts:L74-L77, core-libs/storefront/shared/components/form/form-errors/form-errors.component.ts:L96-L97).
17. **URL protocol-relative.** `//host/path` non è considerato esterno da `GenericLinkComponentService` e finisce in `routerLink` (core-libs/storefront/shared/components/generic-link/generic-link-component.service.ts:L16-L37).
18. **Popover.** La direttiva sottoscrive `eventSubject` senza disiscriversi e usa `ComponentFactoryResolver` deprecato (core-libs/storefront/shared/components/popover/popover.directive.ts:L167-L182, core-libs/storefront/shared/components/popover/popover.directive.ts:L223-L235); il componente ricalcola la posizione a ogni `ngAfterViewChecked` (core-libs/storefront/shared/components/popover/popover.component.ts:L265-L267); trap e autofocus scattano solo con `appendToBody` (core-libs/storefront/shared/components/popover/popover.service.ts:L22-L29).
19. **CSV e download.** L'export non fa escape delle `"` interne né `URL.revokeObjectURL`; l'import fa uno split ingenuo e rimuove tutte le virgolette (core-libs/storefront/shared/services/file/csv/export-csv-file.service.ts:L27-L51, core-libs/storefront/shared/services/file/csv/import-csv-file.service.ts:L86-L87); senza `fileName` il download imposta `download="undefined"` (core-libs/storefront/shared/services/file/file-download.service.ts:L24-L24).
20. `emailValidator` **con valore vuoto.** Restituisce `cxInvalidEmail` anche per stringa vuota; il ramo `!email.length` è irraggiungibile (core-libs/storefront/shared/utils/validators/custom-form-validators.ts:L37-L43).
21. `SupplementHashAnchorsPipe` **e SSR.** Usa `WindowRef.location.href`, che sul server lancia se `SERVER_REQUEST_URL` manca (core-libs/storefront/shared/pipes/suplement-hash-anchors/supplement-hash-anchors.pipe.ts:L28-L34, core-libs/core/src/window/window-ref.ts:L70-L89). DA VERIFICARE l'effetto pratico della purezza della pipe (href non ricalcolato se cambia solo l'URL): dipende dal riuso dell'istanza del componente tra navigazioni.
22. **Card.** Gli output emettono costanti numeriche (delete=1 … cancel=5), non l'indice della card (core-libs/storefront/shared/components/card/card.component.ts:L115-L139).

---

10. Come fare debug

- **Quale componente è mappato su un typeCode?** Cercate il typeCode nell'appendice A03 o con `grep -rn "SimpleResponsiveBannerComponent:" core-libs feature-libs`. Ricordate che uno stesso typeCode può

essere mappato in più librerie: vince l'ultima config applicata (capitolo 11).

- **Cosa riceve il componente?** Mettete un breakpoint in `ComponentDataProvider.get` (`core-libs/storefront/cms-structure/page/component/services/component-data.provider.ts:L35-L59`): vedete i dati statici e quelli dello store. Per i dati grezzi dello store CMS usate NgRx DevTools (slice `cms`, capitolo 19).
- **Link del banner sbagliato.** Controllate quale campo è valorizzato tra `urlLink`, `contentPage`, `product`, `category`: la cascata si ferma al primo (`core-libs/storefront/cms-components/content/banner/banner.component.ts:L137-L161`). Se il link è esterno ma finisce in `routerLink`, verificate il prefisso con le regex di `GenericLinkComponentService` (`core-libs/storefront/shared/components/generic-link/generic-link-component.service.ts:L16-L37`).
- **Voce di menu mancante.** Verificate in DevTools che l'azione `LoadCmsNavigationItems` sia partita e che la chiave `${itemId}_${itemSuperType}` esista negli entry item; ricordate che solo la prima entry e solo `CMSLinkComponent` contano (`core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L166-L170`). Un nodo senza alcuna proprietà viene scartato (`core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L159-L160`).
- **Immagini rotte.** Ispezionate l'host `cx-media`: la classe `is-missing` indica `src` assente (`core-libs/storefront/shared/components/media/media.component.ts:L155-L208`). Se l'URL è sbagliato confrontate `backend.media.baseUrl`/`backend.occ.baseUrl`/`backend.media.prefix` e il toggle `enableMediaPrefix`; un errore di composizione viene loggato da `getBaseUrl` (`core-libs/storefront/shared/components/media/media.service.ts:L414-L426`).
- **Icona invisibile.** Controllate che `icon.symbols` contenga il tipo e che esista una risorsa del tipo giusto: con Font Awesome di default la risorsa LINK ha `url: ''` e il CSS va caricato dall'app (`core-libs/storefront/cms-components/misc/icon/fontawesome-icon.config.ts:L79-L84`).
- **Tab in modalità sbagliata.** Verificate `config.mode` e `config.breakpoint`: senza nessuno dei due la modalità è sempre `TAB` (`core-libs/storefront/cms-components/content/tab/tab.component.ts:L254-L268`).
- **Comportamenti a11y diversi tra ambienti.** Quasi tutte le differenze di tastiera (banner, navigation, carousel, paginazione) dipendono dai feature toggle elencati nella sezione 6: verificate la config `features` dell'app.
- **Test unitari.** Importate `IconTestingModule` per evitare `IconLoaderService` reale (`core-libs/storefront/cms-components/misc/icon/testing/icon-testing.module.ts:L10-L50`); strategie di test nel capitolo 44.

---

11. Domande di autoverifica

1. **Perché `SimpleBannerComponent` e `SimpleResponsiveBannerComponent` producono lo stesso DOM?** Perché `BannerModule` li mappa entrambi (insieme a `BannerComponent`) sulla stessa classe `BannerComponent`. — `core-libs/storefront/cms-components/content/banner/banner.module.ts:L31-L44`
2. **Se `CategoryNavigationComponent` arriva dal backend con `resetMenuOnClose: false`, quale valore vede il componente?** `false`: `ComponentDataProvider.get` emette prima i dati statici (`true`) e poi `{...static, ...backend}`, dove il backend sovrascrive. — `core-libs/storefront/cms-structure/page/component/services/component-data.provider.ts:L44-L51`, `core-libs/storefront/cms-components/navigation/category-navigation/category-navigation.module.ts:L21-L30`
3. **Come fa `SiteContextSelectorComponent` a sapere se è un selettore di lingua o di valuta quando arriva dal CMS?** Il mapping fornisce per ogni istanza un `SiteContextComponentService` con `CmsComponentData`; `getContext` legge `data.context` (LANGUAGE/CURRENCY) e `getInjectedService` risolve il service con `injector.get(contextServiceMap[ctx])`. — `core-libs/storefront/cms-components/misc/site-context-selector/site-context-selector.module.ts:L36-L45`, `core-libs/storefront/cms-components/misc/site-context-selector/site-context-component.service.ts:L91-L125`

4. **Un nodo di navigazione ha due entry: la prima è un `CMSParagraphComponent`, la seconda un `CMSLinkComponent`. Il nodo avrà un URL?** No: `populateNavigationNode` passa solo `entries[0]` a `populateLink`, che considera solo `itemType === 'CMSLinkComponent'`. — core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L146-L148, core-libs/storefront/cms-components/navigation/navigation/navigation.service.ts:L166-L170
5. **Perché il `cx-carousel` non partecipa all'hydration e quanti item per slide calcola in SSR?** È marcato `ngSkipHydration` per differenze CSR/SSR; sul server `clientWidth` è 0 e `calculateItems` restituisce `Math.floor(...) || 1`, cioè 1. — core-libs/storefront/shared/components/carousel/carousel.component.ts:L57-L65, core-libs/storefront/shared/components/carousel/carousel.service.ts:L46-L60
6. **Quando `cx-media` usa `loading="eager"`?** Quando `fetchPriority === ImageFetchPriority.HIGH` (es. passato dal contesto LCP del banner); altrimenti usa `loading` o `imageLoadingStrategy` (default `LAZY`). — core-libs/storefront/shared/components/media/media.component.ts:L217-L222, core-libs/storefront/shared/components/media/media.service.ts:L163-L168
7. **Un link CMS `//cdn.example.com/file.pdf` viene reso con `href` o con `routerLink`?** Con `routerLink`: `isExternalUrl` riconosce solo `http://`, `https://`, `mailto:`, `tel:`. — core-libs/storefront/shared/components/generic-link/generic-link-component.service.ts:L16-L37
8. **Perché `FormErrorsComponent` implementa `ngDoCheck`?** Perché il passaggio a `touched` non emette su `statusChanges`; `ngDoCheck` confronta lo stato precedente e chiama `markForCheck`, differito con `setTimeout` quando `aria-live` è `polite`. — core-libs/storefront/shared/components/form/form-errors/form-errors.component.ts:L96-L112
9. **Con quale meccanismo `TabParagraphContainerComponent` evita un loop infinito nel calcolo dei parametri dei titoli?** `tabCompLoaded` aggiorna `tabTitleParams$` solo se l'uid del figlio non è già nella `Map`. — core-libs/storefront/cms-components/content/tab-paragraph-container/tab-paragraph-container.component.ts:L202-L213
10. **Che problema c'è nel getter `config` di `PaginationBuilder`?** Usa `Object.assign(FALLBACK_PAGINATION_OPTIONS, ...)`, che muta la costante di modulo invece di crearne una copia. — core-libs/storefront/shared/components/list-navigation/pagination/pagination.builder.ts:L370-L375

TAVOLA 45.1 **4.1 Render di un banner CMS**

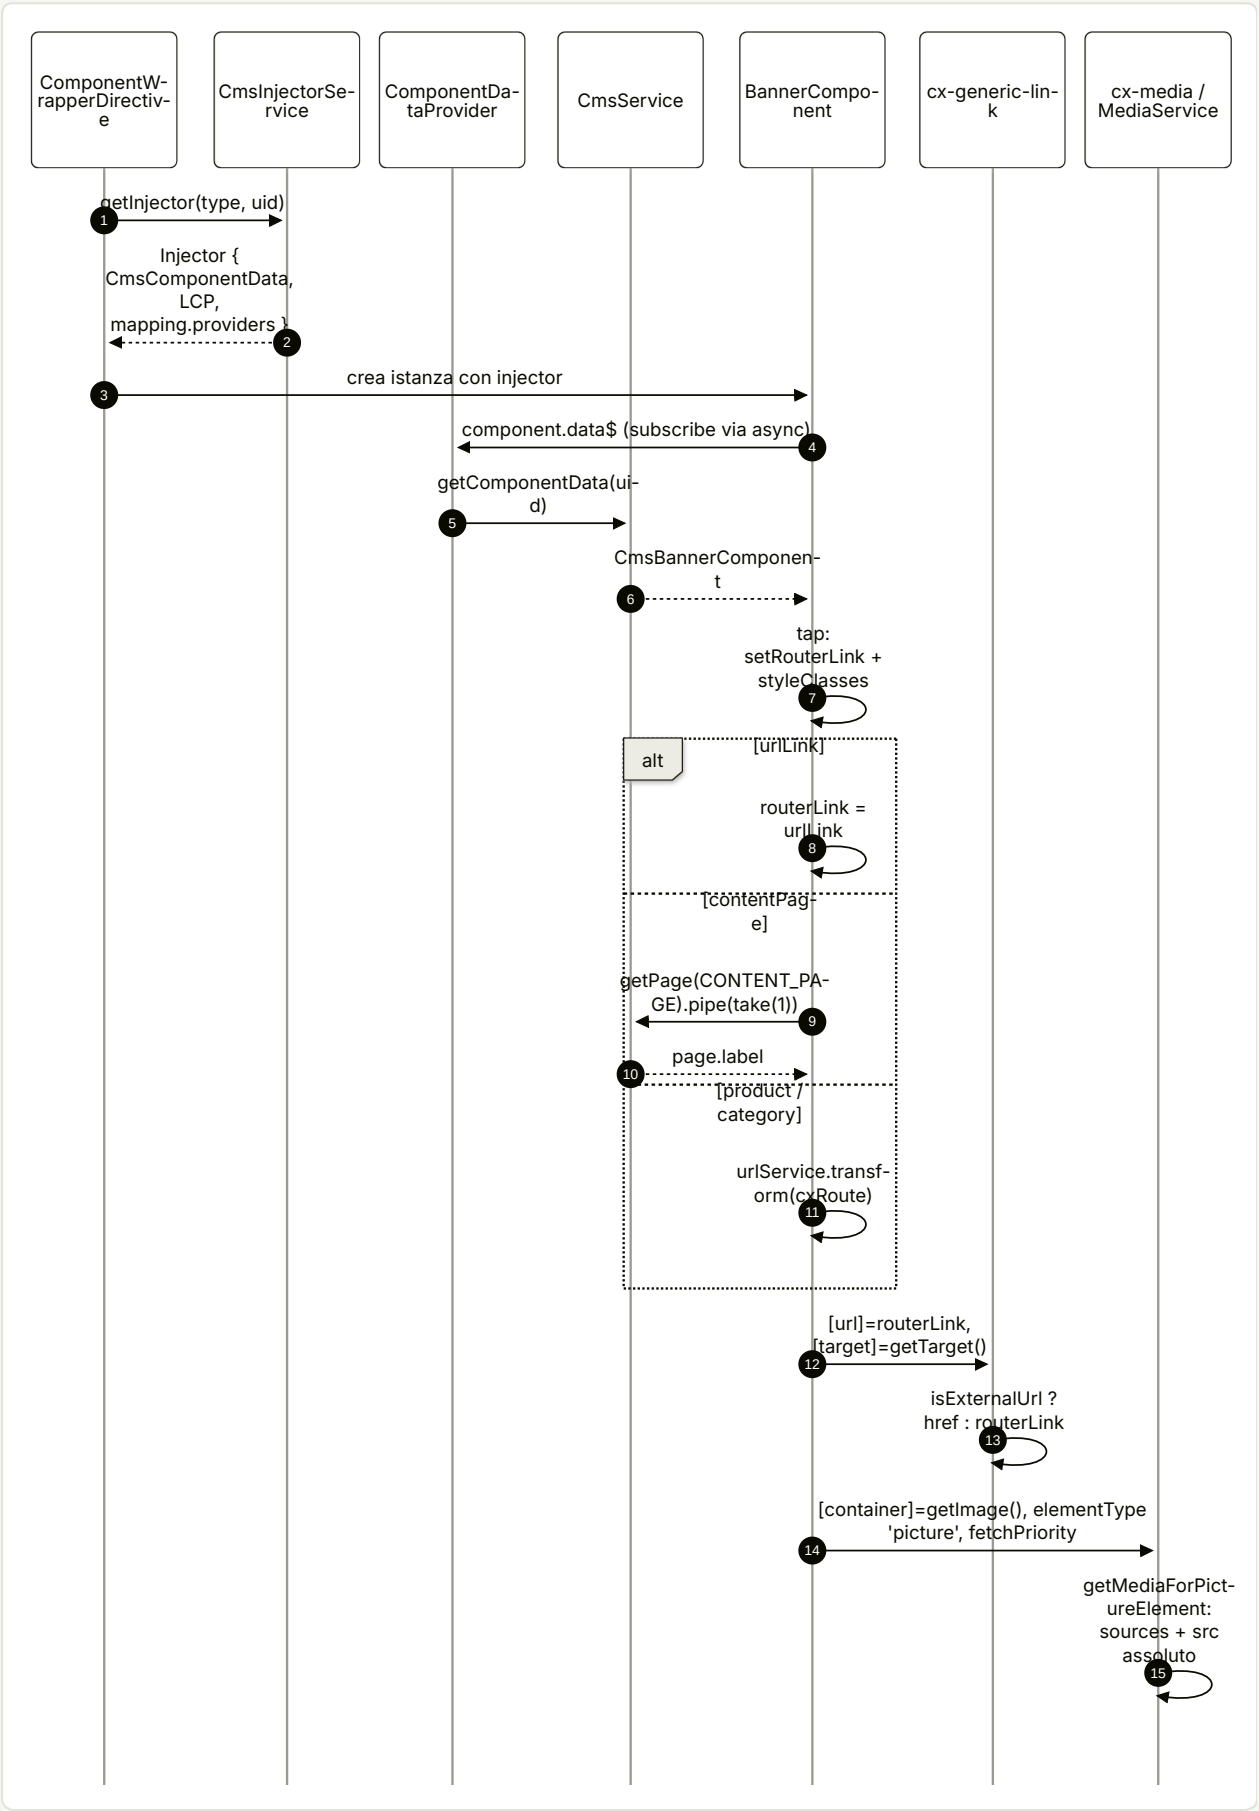

TAVOLA 45.2 **4.2 Costruzione dell'albero di navigazione**

Utility, window e modelli di dominio

Gli "attrezzi" di `@spartacus/core`: `ConverterService`, `resolveApplicable`, `backOff`, normalizzazione degli errori.

IN QUESTO CAPITOLO

1. A cosa serve e perché esiste
2. Mappa dei file
3. Come funziona passo per passo
4. Diagrammi
5. Estratti di codice reale
6. Configurazione
7. Commenti e note notevoli dal sorgente
8. Extension point
9. Trappole, casi limite, comportamenti controintuitivi
10. Come fare debug
11. Domande di autoverifica

Riferimenti allo SHA `5b7a1c2bf2808d7380bc20596d10f4fa710c3da1` (vedi 00-meta).

1. A cosa serve e perché esiste

Ogni capitolo precedente ha incontrato, quasi sempre senza fermarcisi, una manciata di "attrezzi" che `@spartacus/core` mette a disposizione di tutto il resto del framework: il `ConverterService` che normalizza le risposte OCC, `resolveApplicable` che sceglie l'handler giusto tra molti multi-provider, l'operatore `backOff` che ritenta le chiamate fallite, `tryNormalizeHttpError` che rende serializzabile un errore HTTP prima di metterlo in una action NgRx, `WindowRef` che permette di toccare `window` senza esplodere in SSR, e infine le decine di interfacce (`Product`, `Address`, `CmsComponent`, `BaseSite`, …) che danno forma ai dati di dominio. Questo capitolo li raccoglie tutti e li smonta pezzo per pezzo.

Le tre cartelle coinvolte sono riesportate per intero dal `public_api.ts` di core (`core-libs/core/public_api.ts:L26-L36`):

- `core-libs/core/src/util/` — un barrel di 23 moduli (`core-libs/core/src/util/index.ts:L7-L29`) che spazia da pattern architetturali (Applicable, Converter, Command/Query) a operatori RxJS, encoding, regex, script loader, token SSR, helper di test;
- `core-libs/core/src/window/` — il solo `WindowRef` (`core-libs/core/src/window/index.ts:L7-L7`);
- `core-libs/core/src/model/` — 14 file di modelli di dominio (`core-libs/core/src/model/index.ts:L7-L20`), estendibili dalle feature lib tramite *module augmentation* TypeScript.

A questi si aggiungono due utility di `@spartacus/storefront` (`getAddressNumbers` e `FormUtils`), riesportate da `core-libs/storefront/utils/index.ts:L7-L9` tramite `core-libs/storefront/public_api.ts:L30-L30`.

Perché esistono come utility trasversali? Perché risolvono problemi che si ripetono in decine di feature:

PROBLEMA RICORRENTE	UTILITY	QUANTI LA USANO
Scegliere tra più implementazioni registrate come multi-provider	`resolveApplicable`	`PageMetaService`, `HttpErrorInterceptor`, `I18nextBackendService`, `ComponentHandlerService`, `LaunchDialogService` (`core-libs/core/src/cms/facade/page-meta.service.ts:L137-L137`, `core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L62-L64`)
Trasformare payload backend ↔ UI in modo componibile	`ConverterService` + `Converter`	tutti gli adapter OCC (es. `feature-libs/order/occ/adapters/occ-order.adapter.ts:L57-L65`)
Rendere un errore HTTP serializzabile per NgRx	`tryNormalizeHttpError`	113 file non-spec (conteggio grep, dossier F66)
Accedere a `window`/storage/location in modo SSR-safe	`WindowRef`	121 file non-spec (conteggio grep, dossier F94)
Estendere i tipi di dominio senza fork	`declare module '@spartacus/core'`	88 file non-spec (90 blocchi `declare module '@spartacus/core'`)

Due argomenti della cartella `util/` sono trattati altrove e qui solo richiamati: il pattern Command & Query (`core-libs/core/src/util/command-query/index.ts:L7-L8`) in 20 — Facade, command & query, eventi, e `deepMerge` — che, nonostante il nome, **non** sta in `util/` ma in `core-libs/core/src/config/utils/deep-merge.ts:L18-L18` — in 11 — Configurazione. `DirectiveStateTransferService`, pur riesportato dal barrel delle utility di storefront (`core-libs/storefront/utils/index.ts:L8-L8`), appartiene a 39 — SSR ottimizzato.

2. Mappa dei file

PATH	RUOLO
core-libs/core/src/util/index.ts	barrel pubblico di util (23 export; **esclude** glob-utils)
core-libs/core/src/util/applicable.ts	Priority, Applicable, resolveApplicable
core-libs/core/src/util/converter.service.ts	interfaccia Converter e ConverterService (catena di converter con cache per token)
core-libs/core/src/util/combined-injector.ts	CombinedInjector (interno, usato da LazyModulesService)
core-libs/core/src/util/create-from.ts	createFrom (istanze di classi evento da dati)
core-libs/core/src/util/glob-utils.ts	glob → regex (interno, derivato dal service worker Angular)
core-libs/core/src/util/glob.service.ts	GlobService.getValidator (pubblico, usato dal routing)
core-libs/core/src/util/base64.ts	encodeBase64 / decodeBase64 UTF-8, opzione URL-safe
core-libs/core/src/util/http-params-uri.encoder.ts	HttpParamsURIEncoder (codec con encodeURIComponent puro)
core-libs/core/src/util/is-key-invalid.ts	guard anti prototype pollution (lancia)
core-libs/core/src/util/normalize-empty.ts	normalizeEmpty: '' → undefined
core-libs/core/src/util/regex-pattern.ts	costanti regex email/password
core-libs/core/src/util/java-reg-exp-converter/java-reg-exp-converter.ts	JavaRegExpConverter (regex Java dei urlPatterns OCC → JS)
core-libs/core/src/util/java-reg-exp-converter/index.ts	barrel
core-libs/core/src/util/occ-http-error-constants.ts	enum OccHttpErrorType, OccHttpErrorReason (aumentabili)
core-libs/core/src/util/occ-http-error-handlers.ts	predicati isJaloError, isServerError, isAuthorizationError + costanti di retry
core-libs/core/src/util/try-normalize-http-error.ts	tryNormalizeHttpError (HttpErrorResponse → HttpErrorModel)
core-libs/core/src/util/rxjs/index.ts	barrel rxjs (esclude buffer-debounce-time)
core-libs/core/src/util/rxjs/back-off.ts	backOff (retry esponenziale)
core-libs/core/src/util/rxjs/buffer-debounce-time.ts	bufferDebounceTime (interno)
core-libs/core/src/util/rxjs/get-last-value-sync.ts	getLastValueSync

3. Come funziona passo per passo

3.1 La superficie pubblica e ciò che ne resta fuori

Prima di entrare nei singoli meccanismi conviene sapere **cosa è importabile** da `@spartacus/core`, perché il barrel di `util/` non espone tutto ciò che c'è nella cartella:

1. `public_api.ts` di core fa `export *` di `src/model/index`, `src/util/index` e `src/window/index` (core-libs/core/public_api.ts:L26-L36).
2. `util/index.ts` elenca 23 moduli (core-libs/core/src/util/index.ts:L7-L29). Manca `glob-utils`: `globToRegex`, `getGlobMatcher` e `processGlobPatterns` sono interni, è pubblico solo `GlobService` (core-libs/core/src/util/index.ts:L13-L13). Manca anche `combined-injector`: `CombinedInjector` non è riesportato da alcun barrel (dossier Q1).
3. `util/rxjs/index.ts` esporta `back-off`, `get-last-value-sync`, `unite-latest`, `withdraw-on`, `wrap-into-observable`, ma **non** `buffer-debounce-time` (core-libs/core/src/util/rxjs/index.ts:L7-L11). `bufferDebounceTime` è importato con path relativo solo dagli effect `ComponentsEffects`, `ProductEffects`, `ProductSearchByCategoryEffects` e `ProductSearchByCodeEffects` (core-libs/core/src/cms/store/effects/components.effect.ts:L17-L17, core-libs/core/src/product/store/effects/product.effect.ts:L16-L16, core-libs/core/src/product/store/effects/product-search-by-category.effect.ts:L14-L14, core-libs/core/src/product/store/effects/product-search-by-code.effect.ts:L16-L16).
4. `model/index.ts` esporta 14 file ma non `unused.model.ts` (core-libs/core/src/model/index.ts:L7-L20); quest'ultimo è importato solo da `customer-coupon.model.ts` e `product-interest.model.ts` per `Pagination` e `Sort` (core-libs/core/src/model/customer-coupon.model.ts:L8-L8, core-libs/core/src/model/product-interest.model.ts:L8-L8).

Le conseguenze per chi estende (non si può importare per nome ciò che non è nel barrel) sono discusse in 54 — API pubblica vs interna.

3.2 Applicable e `resolveApplicable`: scegliere il miglior candidato

Molti extension point di Spartacus sono **multi-provider**: più classi registrate sullo stesso token, di cui a runtime ne serve una sola. Il contratto è minimale:

1. L'enum `Priority` fissa quattro livelli: `FALLBACK = -50`, `LOW = -10`, `NORMAL = 0`, `HIGH = 10` (core-libs/core/src/util/applicable.ts:L7-L24).
2. L'interfaccia `Applicable` ha due metodi **entrambi opzionali**: `hasMatch?(...params)` e `getPriority?(...params): Priority | number` (core-libs/core/src/util/applicable.ts:L32-L45). Il tipo di ritorno `number` consente priorità intermedie (es. `Priority.NORMAL + 1`).
3. `resolveApplicable(applicables, matchParams, priorityParams)` filtra prima i candidati: passa chi non ha `hasMatch` (match implicito) o il cui `hasMatch(...matchParams)` è `true`; un array `null`/`undefined` è tollerato grazie a `applicables ?? []` (core-libs/core/src/util/applicable.ts:L63-L70).
4. Con 0 o 1 match restituisce subito `matchedApplicables[0]` — cioè il match o `undefined` — **senza** chiamare `getPriority` (core-libs/core/src/util/applicable.ts:L72-L74).
5. Con 2+ match esegue un `reduce`: chi non ha `getPriority` vale `Priority.NORMAL`; il candidato corrente viene scartato solo se `lastPriority > currPriority`, quindi a parità di priorità **vince l'ultimo**, cioè il provider registrato più tardi (core-libs/core/src/util/applicable.ts:L76-L86). Il JSDoc lo dice esplicitamente: "the applicable that was provided later wins" (core-libs/core/src/util/applicable.ts:L47-L62).

Gli usi concreti: `PageMetaService` sceglie il `PageMetaResolver` passando la pagina sia come match che come priority param (core-libs/core/src/cms/facade/page-meta.service.ts:L137-L137); `HttpErrorInterceptor` sceglie l'`HttpErrorHandler` per la risposta (core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L62-L64, vedi 41 — Errori HTTP); lo stesso schema compare in `I18nextBackendService`, `ComponentHandlerService` e `LaunchDialogService` (core-libs/core/src/i18n/i18next/i18next-backend/i18next-backend.service.ts:L34-L36, core-libs/storefront/cms-structure/page/component/services/component-handler.service.ts:L52-L52, core-libs/storefront/layout/launch-dialog/services/launch-dialog.service.ts:L184-L184).

3.3 Converter e `ConverterService`: normalize e serialize a catena

Il livello OCC (vedi 21 — Livello OCC) non consegna alla UI i payload grezzi del backend: li fa passare per converter registrati come multi-provider su un `InjectionToken`. Il motore è `ConverterService`.

1. **Contratto.** `Converter<SOURCE, TARGET>` ha un unico metodo `convert(source, target?)`. Il JSDoc distingue *Normalize* (backend → UI) e *Serialize* (UI → backend) e prevede che i converter si "impilino" per applicare personalizzazioni disaccoppiate (core-libs/core/src/util/converter.service.ts:L13-L30).
2. **Servizio.** `ConverterService` è `providedIn: 'root'`, implementa `OnDestroy` e dipende da `UnifiedInjector` (core-libs/core/src/util/converter.service.ts:L32-L38), l'aggregatore di injector root + lazy descritto in 12 — Feature module e lazy loading.
3. **Cache e invalidazione.** La cache è una `Map<InjectionToken<Converter>, Converter[]>` privata (core-libs/core/src/util/converter.service.ts:L47-L50). Nel costruttore il servizio sottoscrive `unifiedInjector.injectors$` e svuota la cache a ogni nuovo injector, cioè ogni volta che viene caricato un modulo lazy che potrebbe portare converter aggiuntivi (core-libs/core/src/util/converter.service.ts:L39-L44). `ngOnDestroy` chiude la sottoscrizione (core-libs/core/src/util/converter.service.ts:L139-L141).
4. **Lookup.** `getConverters(token)` legge i multi-provider con `getLastValueSync(this.unifiedInjector.getMulti(token))` e mette in cache solo se il valore è definito (core-libs/core/src/util/converter.service.ts:L52-L65). `UnifiedInjector.getMulti` scarta le emissioni con array vuoto e accumula con `scan` le istanze di tutti gli injector; se trova un provider non-multi lancia `Multi-providers mixed with single providers` (core-libs/core/src/lazy-loading/unified-injector.ts:L75-L95).
5. **Presenza.** `hasConverters` è vero solo per un array non vuoto (core-libs/core/src/util/converter.service.ts:L70-L75).
6. **API di uso.**
   - `pipeable(token)` restituisce `map(convertSource)` se ci sono converter, altrimenti un operatore identità che fa solo un cast di tipo (core-libs/core/src/util/converter.service.ts:L80-L88);
   - `pipeableMany(token)` è l'analogo per array, via `convertMany` (core-libs/core/src/util/converter.service.ts:L93-L101);
   - `convert(source, token)` restituisce `source` invariato se non ci sono converter (core-libs/core/src/util/converter.service.ts:L106-L112);
   - `convertMany` converte solo se ci sono converter **e** `sources` è un array, altrimenti restituisce l'input (core-libs/core/src/util/converter.service.ts:L117-L128).
7. **La catena.** `convertSource` fa un `reduce` sui converter partendo da `target = undefined`: ogni converter riceve **lo stesso** `source` e il `target` prodotto dal precedente (core-libs/core/src/util/converter.service.ts:L130-L137). È il *populator pattern*: il primo converter crea l'oggetto UI, i successivi lo arricchiscono.

Uso tipico in un adapter: `catchError → tryNormalizeHttpError`, `backOff({ shouldRetry: isJaloError })`, poi `this.converter.pipeable(ORDER_NORMALIZER)` (feature-libs/order/occ/adapters/occ-order.adapter.ts:L57-L65). La ricetta per scrivere un converter custom è in 52 — Ricette OCC.

3.4 Errori HTTP OCC: normalizzazione, predicati e retry

Questa è la seconda metà della pipeline tipica di un adapter. Il "chi gestisce l'errore dopo" è in 41 — Errori HTTP, error handling, logger e global message; qui interessa come l'errore viene **preparato**.

1. **Perché normalizzare.** Il JSDoc di `tryNormalizeHttpError` dichiara lo scopo: incorporare in modo sicuro gli errori HTTP nei payload delle action NgRx, eliminando le parti non serializzabili di `HttpErrorResponse` (core-libs/core/src/util/try-normalize-http-error.ts:L12-L26). La funzione restituisce l'errore normalizzato o, in mancanza, l'originale: `normalizeHttpError(error, logger) ?? error`.
2. **Il modello.** `HttpErrorModel` è una `class` (unico tipo non-interfaccia di `misc.model.ts`), il che permette a `normalizeHttpError` di riconoscerla con `instanceof` (motivazione non documentata nel sorgente) (core-libs/core/src/model/misc.model.ts:L100-L106, core-libs/core/src/util/try-normalize-http-error.ts:L33-L35). I suoi `details` sono `ErrorModel[]` con `message`, `reason`, `subject`, `subjectType`, `type` (core-libs/core/src/model/misc.model.ts:L92-L98).
3. **Conversione.** `normalizeHttpError` restituisce invariato un `HttpErrorModel`; da un `HttpErrorResponse` crea un `HttpErrorModel` copiando `message`, `status`, `statusText`, `url` (core-libs/core/src/util/try-normalize-http-error.ts:L33-L42).
4. **Dettagli backend.** I `details` vengono da `error.error.errors` (formato errori OCC) oppure, se `error.error.error` è una stringa (formato OAuth), da `{ type: error, message: error_description }` (core-libs/core/src/util/try-normalize-http-error.ts:L44-L54).
5. **Altri errori.** Per qualunque altro tipo, in dev mode logga con `logger.error(...)` e restituisce `undefined`, così `tryNormalizeHttpError` restituisce l'errore originale (core-libs/core/src/util/try-normalize-http-error.ts:L59-L65).
6. **Predicati.** `isJaloError` verifica `err.details?.[0]?.type === 'JaloObjectNoLongerValidError'` (core-libs/core/src/util/occ-http-error-handlers.ts:L12-L14); `isServerError` è vero per status 500..511, `isAuthorizationError` per 401 (core-libs/core/src/util/occ-http-error-handlers.ts:L19-L28). Le costanti `DEFAULT_SERVER_ERROR_RETRIES_COUNT = 2` e `DEFAULT_AUTHORIZATION_ERROR_RETRIES_COUNT = 2` (core-libs/core/src/util/occ-http-error-handlers.ts:L30-L31) sono usate come `maxTries` di un `backOff`: per esempio `OccOrderAdapter` concatena un secondo `backOff({ shouldRetry: isServerError, maxTries: DEFAULT_SERVER_ERROR_RETRIES_COUNT })` dopo quello per Jalo (feature-libs/order/occ/adapters/occ-order.adapter.ts:L92-L102), e il servizio OPF degli hosted fields usa la coppia `isAuthorizationError` / `DEFAULT_AUTHORIZATION_ERROR_RETRIES_COUNT` (integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L119-L122).
7. **Enum aumentabili.** `OccHttpErrorType` (`NotFoundError`, `ClassMismatchError`) e `OccHttpErrorReason` (`notFound`) (core-libs/core/src/util/occ-http-error-constants.ts:L9-L16) stanno nel blocco `AUGMENTABLE_TYPES_START/END` del public_api (core-libs/core/public_api.ts:L54-L57): una feature lib può aggiungere valori di tipo.

3.5 `backOff` e gli altri operatori RxJS

1. `backOff(options)`. Default: `shouldRetry = () => true`, `maxTries = 3`, `delay = 300` ms (core-libs/core/src/util/rxjs/back-off.ts:L39-L42). L'implementazione usa `retry({ delay })` di RxJS: dentro la callback, se `currentRetry > maxTries` o `!shouldRetry(err)` rilancia l'errore, altrimenti restituisce `timer(currentRetry² × delay)` (core-libs/core/src/util/rxjs/back-off.ts:L44-L61). In RxJS 7.8.2 `retry` senza `count` usa `count = Infinity` e passa a `delay` il contatore già incrementato, per cui il primo retry ha `currentRetry = 1` (deps:rxjs-7.8.2/package/dist/cjs/internal/operators/retry.js:L20-L20, deps:rxjs-7.8.2/package/dist/cjs/internal/operators/retry.js:L34-L34, deps:rxjs-7.8.2/package/dist/cjs/internal/operators/retry.js:L46-L46). Con i default si hanno quindi 3 retry, con attese di 300 + 1200 + 2700 = 4200 ms, esattamente come dice il JSDoc di `delay` (core-libs/core/src/util/rxjs/back-off.ts:L26-L26).

2. `bufferDebounceTime(time = 0, scheduler?)` (interno) accumula i valori in un array e li emette in blocco dopo il `debounceTime`, poi azzera il buffer; il buffer vive nella closure creata ogni volta che l'operatore viene applicato a una sorgente (al momento del `pipe`, non della subscription): due subscription allo stesso Observable risultante condividerebbero il buffer (`core-libs/core/src/util/rxjs/buffer-debounce-time.ts:L14-L22`). È ciò che permette agli effect CMS/prodotto di accorpare più richieste di caricamento in una sola chiamata (vedi 15 — CMS core e 24 — Prodotto e ricerca).
3. `getLastValueSync(source)` sottoscrive e disiscrive subito, restituendo l'ultimo valore emesso **in modo sincrono** o `undefined`; il JSDoc lo sconsiglia per l'uso generale (`core-libs/core/src/util/rxjs/get-last-value-sync.ts:L9-L23`). Lo usano `ConverterService.getConverters` (§3.3) e `HttpErrorInterceptor` per leggere gli handler (`core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts:L62-L64`).
4. `uniteLatest(sources)` è `combineLatest(sources).pipe(audit(() => trigger))` dentro un `defer`: la prima emissione è sincrona, le successive sono raggruppate e schedulate con `asapScheduler` (`core-libs/core/src/util/rxjs/unite-latest.ts:L26-L47`). Il JSDoc spiega lo scopo: se più sorgenti emettono "nello stesso momento", `uniteLatest` emette una sola volta dove `combineLatest` emetterebbe una volta per sorgente (`core-libs/core/src/util/rxjs/unite-latest.ts:L15-L25`). Usato da `PageMetaService` e `ProductLoadingService` (`core-libs/core/src/cms/facade/page-meta.service.ts:L99-L99`, `core-libs/core/src/product/services/product-loading.service.ts:L75-L75`).
5. `withdrawOn(notifier)` riscrive lo stream come `notifier.pipe(startWith(undefined), switchMap(() => source))`: a ogni emissione del notifier la sorgente viene ri-sottoscritta, abbandonando la trasformazione in corso (`core-libs/core/src/util/rxjs/withdraw-on.ts:L19-L27`).
6. `wrapIntoObservable(value)` restituisce l'Observable così com'è, converte un thenable con `from(Promise.resolve(value))`, altrimenti `of(value)`; `isPromise` è duck typing su `then` (`core-libs/core/src/util/rxjs/wrap-into-observable.ts:L17-L36`). `GuardsComposer` lo usa per normalizzare il risultato di `canActivate` (`core-libs/storefront/cms-structure/services/guards-composer.ts:L65-L65`).

3.6 `CombinedInjector` e `createFrom`

1. `CombinedInjector` implementa `Injector` combinando un `mainInjector` con una lista di `complementaryInjectors`; il JSDoc lo indica per istanziare moduli lazy che devono vedere le istanze dei propri moduli di dipendenza (`core-libs/core/src/util/combined-injector.ts:L17-L35`).
2. Se riceve l'opzione `self` restituisce `notFoundValue` se fornito, altrimenti lancia: non supporta dipendenze `@Self` (`core-libs/core/src/util/combined-injector.ts:L44-L51`).
3. La risoluzione procede in tre passi — (a) a livello `self` in ogni complementary injector, in ordine; (b) a tutti i livelli in ogni complementary injector; (c) fallback a `mainInjector.get(token, notFoundValue)` — usando come sentinella l'oggetto privato `NOT_FOUND_SYMBOL = {}` (`core-libs/core/src/util/combined-injector.ts:L15-L15`, `core-libs/core/src/util/combined-injector.ts:L53-L70`).
4. `LazyModulesService` lo crea solo quando ci sono **2+** moduli di dipendenza; con uno usa direttamente il suo injector, con zero il proprio (`core-libs/core/src/lazy-loading/lazy-modules.service.ts:L83-L94`). Il contesto completo è in 12 — Feature module e lazy loading.
5. `createFrom(type, data)` è un one-liner: `Object.assign(new type(), data)`; serve a creare istanze di classi evento (`core-libs/core/src/util/create-from.ts:L15-L17`; eventi in 20).

3.7 Glob: pattern di URL per il routing

1. `glob-utils.ts` porta il copyright Google/Angular: è derivato dal service worker di Angular (`core-libs/core/src/util/glob-utils.ts:L1-L7`).

2. Le regole di escaping trasformano `.` → `\.`, `+` → `\+`, `*` → `[^/]*` e `?` → `[^/]` (o `\?` con `literalQuestionMark`) (core-libs/core/src/util/glob-utils.ts:L9-L24).
3. `globToRegex` lavora per segmenti separati da `/`: `**` diventa `(?:.+\/)?` se non è l'ultimo segmento, `.*` se lo è; gli altri segmenti vengono escapati e uniti con `\/` (core-libs/core/src/util/glob-utils.ts:L38-L64).
4. `processGlobPatterns` marca come negativo un pattern che inizia con `!`, lo rimuove e ancora la regex con `^...$`; chiama `globToRegex(url)` senza `literalQuestionMark` (core-libs/core/src/util/glob-utils.ts:L91-L99).
5. `getGlobMatcher` restituisce un predicato vero se almeno un pattern positivo matcha e nessun negativo matcha (core-libs/core/src/util/glob-utils.ts:L71-L86); `GlobService.getValidator` (root, pubblico) duplica la stessa logica (core-libs/core/src/util/glob.service.ts:L10-L32).
6. Il consumatore è `UrlMatcherService.getFromGlob`, che costruisce un `UrlMatcher` Angular ricomponendo il path completo `/seg1/seg2` e testandolo col validator (core-libs/core/src/routing/services/url-matcher.service.ts:L178-L190; routing in 14).

3.8 Encoding, sicurezza e regex

1. **Base64.** `encodeBase64` codifica UTF-8 con `TextEncoder`, poi `btoa` su una binary string; con `urlSafe` applica l'alfabeto RFC 4648 §5 (core-libs/core/src/util/base64.ts:L16-L29). `toUrlSafe` sostituisce `+`→`-`, `/`→`_` e rimuove il padding `=` (core-libs/core/src/util/base64.ts:L54-L59). `decodeBase64` inverte: ripristina alfabeto e padding, `atob`, poi `TextDecoder` (core-libs/core/src/util/base64.ts:L31-L52). Unico consumatore: `FederatedLoginContextSerializerService`, con `urlSafe: true` (core-libs/core/src/federated-login/services/federated-login-context-serializer.service.ts:L8-L8, core-libs/core/src/federated-login/services/federated-login-context-serializer.service.ts:L27-L27).
2. `HttpParamsURIEncoder` implementa `HttpParameterCodec` con solo `encodeURIComponent`/`decodeURIComponent`, perché l'encoder di default di Angular "de-codifica" alcuni caratteri ammessi da RFC 3986 (core-libs/core/src/util/http-params-uri.encoder.ts:L7-L23). È usato in `OccEndpointsService` per i query param degli URL OCC e negli adapter di pagamento checkout (core-libs/core/src/occ/services/occ-endpoints.service.ts:L126-L126, feature-libs/checkout/base/occ/adapters/occ-checkout-payment.adapter.ts:L203-L203).
3. `isKeyInvalid(key)` non restituisce un boolean: lancia `Error` se la chiave è `__proto__`, `constructor` o `prototype` (core-libs/core/src/util/is-key-invalid.ts:L17-L27). `ProductLoadingService` lo chiama su `productCode` prima di indicizzare la sua cache interna (core-libs/core/src/product/services/product-loading.service.ts:L50-L50, core-libs/core/src/product/services/product-loading.service.ts:L59-L59).
4. `normalizeEmpty` converte `''` in `undefined` per poter usare `??` (core-libs/core/src/util/normalize-empty.ts:L14-L18); lo usa per esempio il riepilogo OPF B2B checkout (integration-libs/opf/b2b-checkout/components/opf-b2b-checkout-review/opf-b2b-checkout-review.component.ts:L149-L149).
5. **Regex.** `regex-pattern.ts` esporta `EMAIL_PATTERN`, `PASSWORD_PATTERN` (maiuscola + cifra + speciale, almeno 6), pattern atomici per i requisiti password, `STRONG_PASSWORD_PATTERN`, `SECURE_PASSWORD_PATTERN` (8-128, nessun carattere ripetuto consecutivo) e `ENDS_WITH_LEGAL_CHARACTER_PATTERN` (core-libs/core/src/util/regex-pattern.ts:L7-L36).

3.9 `JavaRegExpConverter`: dal `BaseSite` OCC all'URL corrente

1. `JavaRegExpConverter` è `providedIn: 'root'` e inietta `LoggerService` con `inject()` (core-libs/core/src/util/java-reg-exp-converter/java-reg-exp-converter.ts:L10-L12).
2. La regex `EXTRACT_JAVA_REGEXP_MODIFIERS` estrae un prefisso opzionale `(?modifiers)` di sole lettere minuscole e il resto del pattern (core-libs/core/src/util/java-reg-exp-converter/java-reg-exp-converter.

ts:L14-L29).

3. `toJsRegExp` passa i modificatori Java **così come sono** come flag JS (`new RegExp(jsSyntax, modifiers)`); se il costruttore lancia restituisce `null` e, solo in dev mode, logga un warning (core-libs/core/src/util/java-reg-exp-converter/java-reg-exp-converter.ts:L42-L58).
4. Il consumatore è `SiteContextConfigInitializer.isCurrentBaseSite`, che testa l'URL corrente contro gli `urlPatterns` del `BaseSite` restituito da OCC (core-libs/core/src/site-context/config/config-loader/site-context-config-initializer.ts:L100-L106; `BaseSite.urlPatterns` in core-libs/core/src/model/misc.model.ts:L116-L133). Il flusso di inizializzazione del site context è in 13 — Site context.

3.10 `ScriptLoader`: script di terze parti, SSR-aware

1. `ScriptPlacement` ha `HEAD = 'head'` e `BODY = 'body'`; `ScriptLoader` è root e inietta `DOCUMENT` e `PLATFORM_ID` (core-libs/core/src/util/script-loader.service.ts:L10-L22).
2. `embedScript` accetta `src`, `params`, `attributes`, `callback`, `errorCallback`, `placement` (default `HEAD`), `disableKeyRestriction` (core-libs/core/src/util/script-loader.service.ts:L36-L53).
3. In SSR lo script **non** viene aggiunto se ci sono `callback` o `errorCallback` (non avrebbero senso sul server); nel browser non viene aggiunto se esiste già uno `script[src="..."]` identico; in SSR il controllo dei duplicati è saltato (core-libs/core/src/util/script-loader.service.ts:L55-L63).
4. Lo script creato ha sempre `async = true` e `defer = true` (core-libs/core/src/util/script-loader.service.ts:L65-L68).
5. Gli `attributes` con chiave `data-*` — o, con `disableKeyRestriction`, qualsiasi chiave che non sia già una proprietà di `HTMLScriptElement` — diventano attributi via `setAttribute`; tutte le altre sono assegnate come proprietà DOM (core-libs/core/src/util/script-loader.service.ts:L70-L82).
6. `callback`/`errorCallback` sono agganciati a `load`/`error` e lo script è appeso a `head` o `body` (core-libs/core/src/util/script-loader.service.ts:L84-L93). `hasScript` usa `querySelector('script[src="..."]')` e `parseParams` costruisce `?k=v&...` con `encodeURI` (core-libs/core/src/util/script-loader.service.ts:L99-L121).

3.11 `WindowRef` e i token SSR

`WindowRef` è il modo canonico di toccare il "mondo browser" in Spartacus. Il funzionamento è interamente guidato da `PLATFORM_ID` e dai due token di `ssr.tokens.ts`:

1. `SERVER_REQUEST_URL` e `SERVER_REQUEST_ORIGIN` sono `InjectionToken<string>` **senza** factory di default (core-libs/core/src/util/ssr.tokens.ts:L12-L21). Lato server li forniscono `provideServer()` (factory basate sulle `ServerOptions`) e `getServerRequestProviders()` (factory sulla `REQUEST` Express) (core-libs/setup/ssr/providers/ssr-providers.ts:L27-L37, core-libs/setup/ssr/providers/ssr-providers.ts:L53-L65; dettagli in 39).
2. `WindowRef` è root; inietta `DOCUMENT`, `PLATFORM_ID` e, come `@Optional`, i due token; espone `readonly document: Document` (core-libs/core/src/window/window-ref.ts:L13-L27). In Angular 21 `DOCUMENT` di `@angular/common` è una riesportazione di quello di `@angular/core` (angular:packages/common/src/common.ts:L116-L116).
3. `isBrowser()` delega a `isPlatformBrowser(platformId)`, che confronta con la stringa `'browser'` (core-libs/core/src/window/window-ref.ts:L33-L35, angular:packages/common/src/platform_id.ts:L9-L9, angular:packages/common/src/platform_id.ts:L16-L18).
4. `nativeWindow` restituisce il `window` globale solo nel browser, altrimenti `undefined` (core-libs/core/src/window/window-ref.ts:L41-L44); `sessionStorage` e `localStorage` sono getter che passano da `nativeWindow` e restituiscono `undefined` in SSR (core-libs/core/src/window/window-ref.ts:L50-L60).

5. `location` nel browser restituisce `document.location`; in SSR restituisce un `Partial<Location>` con soli `href` (da `SERVER_REQUEST_URL`) e `origin` (da `SERVER_REQUEST_ORIGIN`), e **lancia** se uno dei due manca (core-libs/core/src/window/window-ref.ts:L70-L89).
6. `resize$` in SSR emette `of(null)`; nel browser è `fromEvent(window, 'resize')` con `debounceTime(300)`, `startWith({ target: window })` e `distinctUntilChanged()` (core-libs/core/src/window/window-ref.ts:L97-L107). È la sorgente da cui parte il `BreakpointService` (core-libs/storefront/layout/breakpoint/breakpoint.service.ts:L41-L41; vedi 18 — Layout e breakpoint), e lo usano anche carousel e popover (core-libs/storefront/shared/components/carousel/carousel.service.ts:L33-L33, core-libs/storefront/shared/components/popover/popover.component.ts:L239-L239).

3.12 `AbstractBrowserTabNotificationService`: messaggi tra tab

Classe base generica per comunicare tra più tab dello stesso storefront tramite `BroadcastChannel`.

1. **Formato di trasporto.** `TabNotificationWrapper<T>` è `{ baseSite, payload }`; `isTabNotificationWrapperEvent` è un type guard che verifica che `event.data` sia un oggetto con entrambe le chiavi (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L14-L34).
2. **Contratto per le sottoclassi.** Vanno definiti `channelId` (nome del canale) e `isPayloadOfExpectedType`; `isolateBySite` vale `true` di default; la classe inietta `BaseSiteService`, `LoggerService`, `WindowRef`, `DestroyRef` (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L49-L58); `isPayloadOfExpectedType` è dichiarato `abstract` (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L134-L134).
3. **Uscita.** Un `Subject` interno viene avvolto con il base site attivo (`withLatestFrom(getActive())`) e pubblicato con `channel?.postMessage` (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L60-L67).
4. **Entrata.** `notifications$` applica in sequenza: guard del wrapper, `isPayloadOfExpectedType`, estrazione di `data`, confronto col base site attivo, estrazione del `payload` (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L73-L84); `passesSiteIsolation` è `!this.isolateBySite || currentBaseSite === wrapper.baseSite` (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L122-L127).
5. **Avvio.** `listen()` agisce solo nel browser: apre il canale, inoltra i `message` su `inboundEvents$`, sottoscrive lo stream in uscita e registra su `DestroyRef` chiusura e disiscrizione; eventuali eccezioni sono loggate come warning (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L93-L111).
6. **Invio.** `sendNotification` spinge sul `Subject`: se `listen()` non è stato chiamato il payload viene scartato in silenzio, e il JSDoc lo documenta (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L113-L120).
7. **Unica sottoclasse.** `AuthNotificationService` accetta solo stringhe dell'enum `AuthNotificationType` (core-libs/core/src/auth/user-auth/facade/auth-notification.service.ts:L26-L39). Il suo `listen()` è chiamato da un initializer solo se il feature toggle `propagateLogoutToAllTabs` è attivo, e `AuthService.coreLogout` invia `LOGOUT` sotto lo stesso toggle (core-libs/core/src/auth/user-auth/user-auth.module.ts:L85-L92, core-libs/core/src/auth/user-auth/facade/auth.service.ts:L195-L199); la ricezione è gestita in `AuthService.subscribeToAuthNotifications` (core-libs/core/src/auth/user-auth/facade/auth.service.ts:L240-L247). Contesto in 22 — Autenticazione e 42 — Feature toggle.

3.13 Helper vari: type guard, tipi, confronto, tempo

- `isNotUndefined` controlla `typeof value !== 'undefined'`; `isNotNullable` aggiunge `value !== null` e restringe a `NonNullable<T>` (core-libs/core/src/util/type-guards.ts:L7-L13) — utili come predicati di `filter` in RxJS.
- `RequiredPick<T, K>` rende obbligatorie le chiavi `K` lasciando invariate le altre: `Omit<T, K> & Required<Pick<T, K>>` (core-libs/core/src/util/type-utils.ts:L7-L11).
- `ObjectComparisonUtils.shallowEqualObjects` confronta con `===` le chiavi proprie e il loro numero (core-libs/core/src/util/object-comparison-utils.ts:L8-L30); `deepEqualObjects` richiede che entrambi siano `instanceof Object` con lo stesso `constructor` e confronta ricorsivamente le proprietà proprie in entrambe le direzioni (core-libs/core/src/util/object-comparison-utils.ts:L32-L75); `countOfDeepEqualObjects` e `indexOfFirstOccurrence` lavorano su array (core-libs/core/src/util/object-comparison-utils.ts:L77-L92).
- `TimeUtils.getLocalTimezoneOffset(invert?)` produce `±HH:MM` dall'offset del browser, invertendo il segno di `getTimezoneOffset` (core-libs/core/src/util/time-utils.ts:L16-L24); `convertDateToDatetime` aggiunge `T00:00:00` o `T23:59:59` più l'offset, `convertDatetimeToDate` fa il percorso inverso restituendo `YYYY-MM-DD` (core-libs/core/src/util/time-utils.ts:L26-L38).
- `TestingTimeUtils` — esportato nell'API pubblica (core-libs/core/src/util/index.ts:L25-L25) — sostituisce temporaneamente `Date.prototype.toLocaleTimeString` o `getTimezoneOffset`, esegue la callback e ripristina l'originale (core-libs/core/src/util/testing-time-utils.ts:L7-L21).
- In storefront, `getAddressNumbers(address, textPhone, textMobile)` produce la riga dei recapiti: solo mobile se `cellphone === phone`, entrambe le righe separate da `\n` se diversi, solo quella presente, oppure `undefined` (core-libs/storefront/utils/address-number-utils.ts:L12-L33). `FormUtils.deepUpdateValueAndValidity` ricorre su `UntypedFormGroup`/`UntypedFormArray` e chiama `updateValueAndValidity({ onlySelf: true, emitEvent })` su ogni controllo, figli prima del genitore (core-libs/storefront/utils/form-utils.ts:L16-L52).

3.14 I modelli di dominio

I file di `model/` sono quasi solo **tipi**: interfacce TypeScript che descrivono i dati "UI" (cioè già normalizzati dai converter OCC) consumati da facade e componenti.

1. **Opzionalità quasi totale.** Le proprietà sono praticamente tutte opzionali (`?`), con poche eccezioni come `ListModel.ids`, `EntitiesModel.values` (core-libs/core/src/model/misc.model.ts:L60-L71), `CaptchaConfig.enabled` (core-libs/core/src/model/misc.model.ts:L135-L138), `SiteTheme.*` (core-libs/core/src/model/misc.model.ts:L140-L143) e `CmsPickupItemDetails.*` (core-libs/core/src/model/cms.model.ts:L249-L252). La scelta riflette i payload OCC, che variano in base ai `fields` richiesti.
2. `misc.model.ts` definisce i tipi trasversali: `Currency`, `Time`, `GeoPoint`, `Language`, `Principal`, `User`, `ListModel`, `EntitiesModel<T>`, `PaginationModel`, `SortModel`, `Title`, `ErrorModel`, `HttpErrorModel`, `BaseStore`, `BaseSite`, `CaptchaConfig`, `SiteTheme` (core-libs/core/src/model/misc.model.ts:L10-L143). `BaseSite` include `urlPatterns` (regex Java, §3.9), `urlEncodingAttributes`, `requiresAuthentication`, `isolated`, `captchaConfig`, `theme` (core-libs/core/src/model/misc.model.ts:L116-L133). `PaginationModel` e `SortModel` sono i modelli UI di paginazione e ordinamento, distinti da `Pagination`/`Sort` di `unused.model.ts` (core-libs/core/src/model/misc.model.ts:L73-L85, core-libs/core/src/model/unused.model.ts:L33-L43).
3. **Prodotto.** `Product` raccoglie i campi OCC (codice, nome, `slug`, immagini, prezzi, stock, varianti, classificazioni, riferimenti, recensioni, promozioni) più `sapUnit` e `productTypes` (core-libs/core/src/model/product.model.ts:L167-L210); `slug` è documentato come base per gli URL "pretty" della PDP (core-libs/core/src/model/product.model.ts:L181-L186). Enum: `VariantType`, `PriceType`, `VariantQualifier`, `ProductTypes` (core-libs/core/src/model/product.model.ts:L57-L66, core-libs/core/src/model/

product.model.ts:L222-L230, core-libs/core/src/model/product.model.ts:L267-L271). `ProductReferences` e `Images` sono dizionari indicizzati per stringa; `ImageGroup` è indicizzato per formato (core-libs/core/src/model/product.model.ts:L157-L159, core-libs/core/src/model/image.model.ts:L7-L9, core-libs/core/src/model/image.model.ts:L41-L43). `Image.width/height` non vengono dal CMS: sono stati aggiunti per impostare manualmente le dimensioni nel `MediaComponent` (core-libs/core/src/model/image.model.ts:L18-L33). `PointOfServiceStock` ripete i campi di `PointOfService` aggiungendo `stockInfo` invece di estenderlo (core-libs/core/src/model/product.model.ts:L232-L247).

4. **Ricerca.** `Facet` documenta `expanded`, `topValueCount` e `topValues` (duplicato OCC normalizzato in `topValueCount`) (core-libs/core/src/model/product-search.model.ts:L43-L60); `ProductSearchPage` usa `PaginationModel`/`SortModel` e contiene `breadcrumbs`, `facets`, `freeTextSearch`, `keywordRedirectUrl`, `spellingSuggestion` (core-libs/core/src/model/product-search.model.ts:L68-L79); `ClearSearch` ha `clearPageResults` e `clearSearchboxResults` (core-libs/core/src/model/product-search.model.ts:L85-L88).
5. **CMS.** `CmsComponent` è la base dei dati di ogni componente CMS: `uid`, `typeCode`, `name`, `modifiedTime`, `otherProperties`, `composition.inner`, `styleClasses` (core-libs/core/src/model/cms.model.ts:L7-L32). `PageType` ha `ContentPage`, `ProductPage`, `CategoryPage`, `CatalogPage` (core-libs/core/src/model/cms.model.ts:L38-L43). Il file prosegue con le interfacce dei componenti standard che estendono `CmsComponent` — link, search box, paragraph, banner, carousel, navigation, add to cart, video, pickup item details, … (core-libs/core/src/model/cms.model.ts:L45-L252). Molti attributi semanticamente booleani o liste sono tipizzati `string`, riflettendo il payload CMS di OCC (core-libs/core/src/model/cms.model.ts:L88-L92, core-libs/core/src/model/cms.model.ts:L137-L144, core-libs/core/src/model/cms.model.ts:L219-L224). I media di banner e video possono essere singoli o responsive (`desktop`, `mobile`, `tablet`, `widescreen`) (core-libs/core/src/model/cms.model.ts:L106-L117). Come questi dati arrivano ai componenti è in 15 e 16.
6. **Indirizzi, consensi, B2B, pagamenti, punti vendita.** `Address` con `titleCode`, `line1/2`, `town`, `postalCode`, `region`, `country`, `cellphone`, `phone`, `defaultAddress`, `visibleInAddressBook`, `formattedAddress`, … (core-libs/core/src/model/address.model.ts:L38-L67); `CountryType` e `AddressValidation` (core-libs/core/src/model/address.model.ts:L14-L17, core-libs/core/src/model/address.model.ts:L69-L74). `consent.model.ts` definisce consensi, consensi anonimi, `ANONYMOUS_CONSENT_STATUS` e la costante `ANONYMOUS_CONSENTS_HEADER = 'X-Anonymous-Consents'` (core-libs/core/src/model/consent.model.ts:L7-L32), letta dall'interceptor dei consensi anonimi (core-libs/core/src/anonymous-consents/http-interceptors/anonymous-consents-interceptor.ts:L61-L61). `org-unit.model.ts` definisce `CostCenter`, `B2BUnit`, `B2BUser extends User`, `B2BApprovalProcess`, `B2BUserRole`, `B2BUserRight` (core-libs/core/src/model/org-unit.model.ts:L11-L49). `PaymentDetails` (core-libs/core/src/model/payment.model.ts:L13-L28), `PointOfService` e `OpeningSchedule` (core-libs/core/src/model/point-of-service.model.ts:L11-L49).
7. **Modelli "my account".** `customer-coupon.model.ts`, `notification-preference.model.ts` e `product-interest.model.ts` (core-libs/core/src/model/customer-coupon.model.ts:L10-L36, core-libs/core/src/model/notification-preference.model.ts:L7-L16, core-libs/core/src/model/product-interest.model.ts:L10-L29).
8. `ScopedData<T>` avvolge un `data$` Observable con lo `scope` associato (core-libs/core/src/model/scoped-data.ts:L9-L15): `ScopedProductData` la estende per il caricamento di prodotto per scope (core-libs/core/src/product/connectors/product/scoped-product-data.ts:L13-L13; vedi 24).

3.15 Module augmentation dei modelli

I modelli sono interfacce proprio perché TypeScript permette di **fonderle** (declaration merging) da qualsiasi altro file, a patto di rientrare nel modulo giusto:

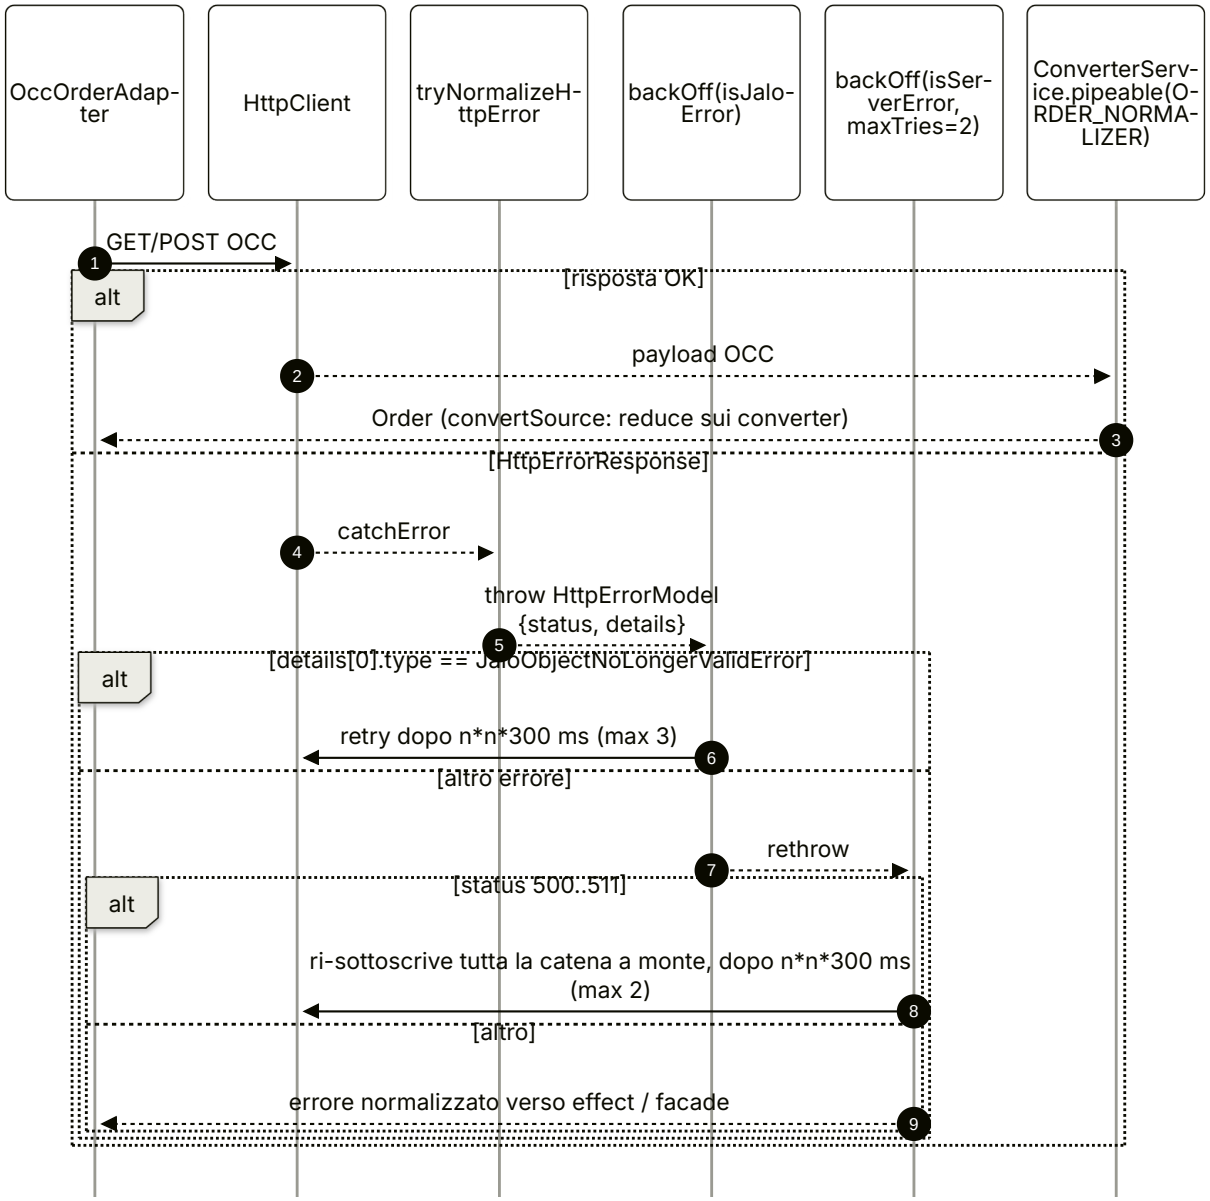
1. Una feature lib scrive `declare module '@spartacus/core' { interface Product { ... } }`; 88 file non-spec del repo lo fanno, per 90 blocchi in tutto (alcuni file ne hanno due, es. `feature-libs/subscription-billing/root/model/subscription-product.model.ts:L98-L98`, `feature-libs/subscription-billing/root/model/subscription-product.model.ts:L105-L105`). Esempi: product-configurator aggiunge a `Product` i campi `configurable` e `configuratorType` (`feature-libs/product-configurator/common/core/model/augmented-core.model.ts:L8-L13`); organization aggiunge a `B2BUnit` `parentOrgUnit`, `approvalProcess`, `administrators`, … (`feature-libs/organization/administration/core/model/augmented-core.model.ts:L9-L25`).
2. Il public_api di core racchiude tra i commenti `AUGMENTABLE_TYPES_START/END` un blocco di re-export espliciti: `AuthToken`, `Config`, `Address`, `B2BUnit`, `B2BUser`, `B2BUserRole`, `CostCenter`, `Facet`, `ProductSearchPage`, `Price`, `Product`, `Stock`, `OccHttpError*`, … (`core-libs/core/public_api.ts:L38-L58`).
3. Esiste un builder `augmented-types` che sposta quel blocco dal d.ts del public API al d.ts radice del pacchetto, come workaround a microsoft/TypeScript#9532 e #18877 (`tools/build-lib/augmented-types/index.ts:L20-L32`, `tools/build-lib/augmented-types/index.ts:L117-L148`). Il target `build` di core, però, usa l'executor `./tools/build-lib:declaration-merging`, che corregge i path relativi dei `declare module '../foo'` nel d.ts appiattito (workaround ng-packagr#3085) (`core-libs/core/project.json:L8-L13`, `tools/build-lib/declaration-merging/index.ts:L22-L28`, `tools/build-lib/declaration-merging/index.ts:L108-L111`).
4. Nessun `project.json` referenzia `augmented-types`, e `declaration-merging` non tocca i delimitatori: alla SHA il blocco è un semplice re-export esplicito, e l'augmentation funziona perché i `declare module '@spartacus/core'` puntano all'entry del pacchetto (`tools/build-lib/declaration-merging/index.ts:L108-L128`, `core-libs/core/project.json:L8-L13`). Nessuno script `.sh`, workflow `.yml` o `project.json` invoca il builder `augmented-types`: compare solo nella sua registrazione (`tools/build-lib/builders.json:L3-L5`, `tools/build-lib/package.json:L5-L5`).
5. Un **enum** si può aumentare solo a livello di tipo: subscription-billing aggiunge `SUBSCRIPTION` a `ProductScope` con `declare module` e poi assegna il valore a runtime con un cast `(ProductScope as any)['SUBSCRIPTION'] = 'subscription'` (`feature-libs/subscription-billing/root/model/subscription-product.model.ts:L98-L110`).

---

4. Diagrammi

4.1 Pipeline di un adapter OCC: errore, retry, conversione

Il diagramma segue l'esempio di `OccOrderAdapter` (`feature-libs/order/occ/adapters/occ-order.adapter.ts:L92-L102`): `tryNormalizeHttpError` (§3.4), due `backOff` in cascata (§3.5) e `pipeable` (§3.3).

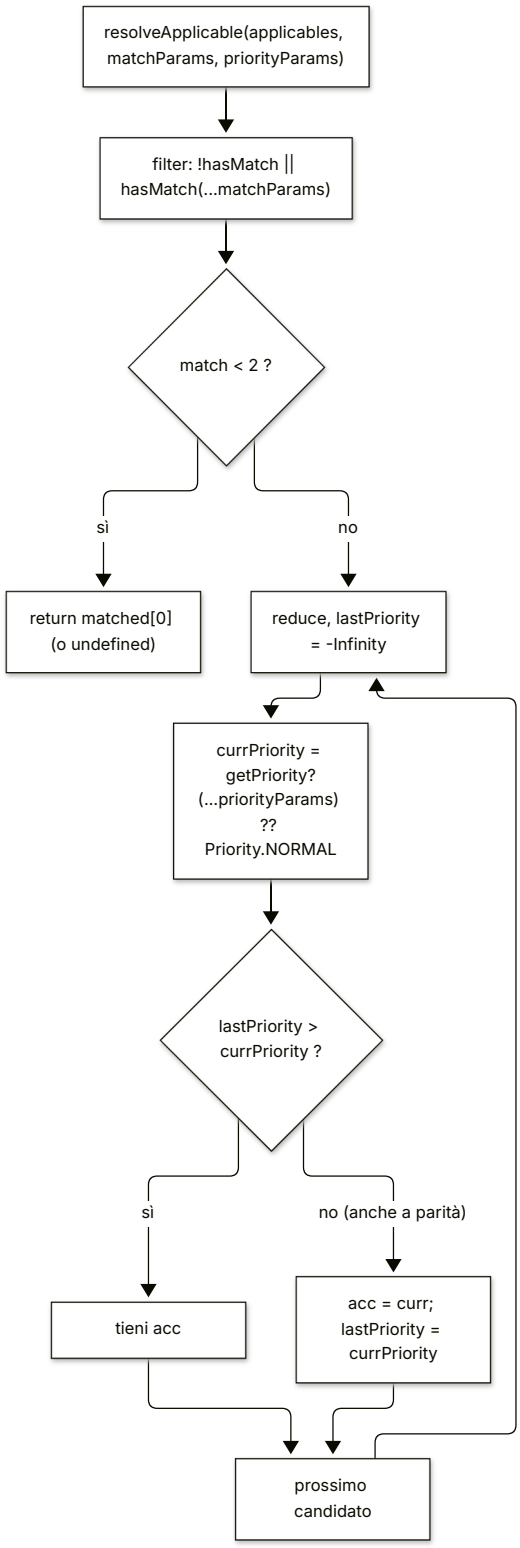


4.2 `ConverterService`: cache, lookup e catena

■ **TAVOLA 46.1** diagramma a tutta pagina, in fondo al capitolo

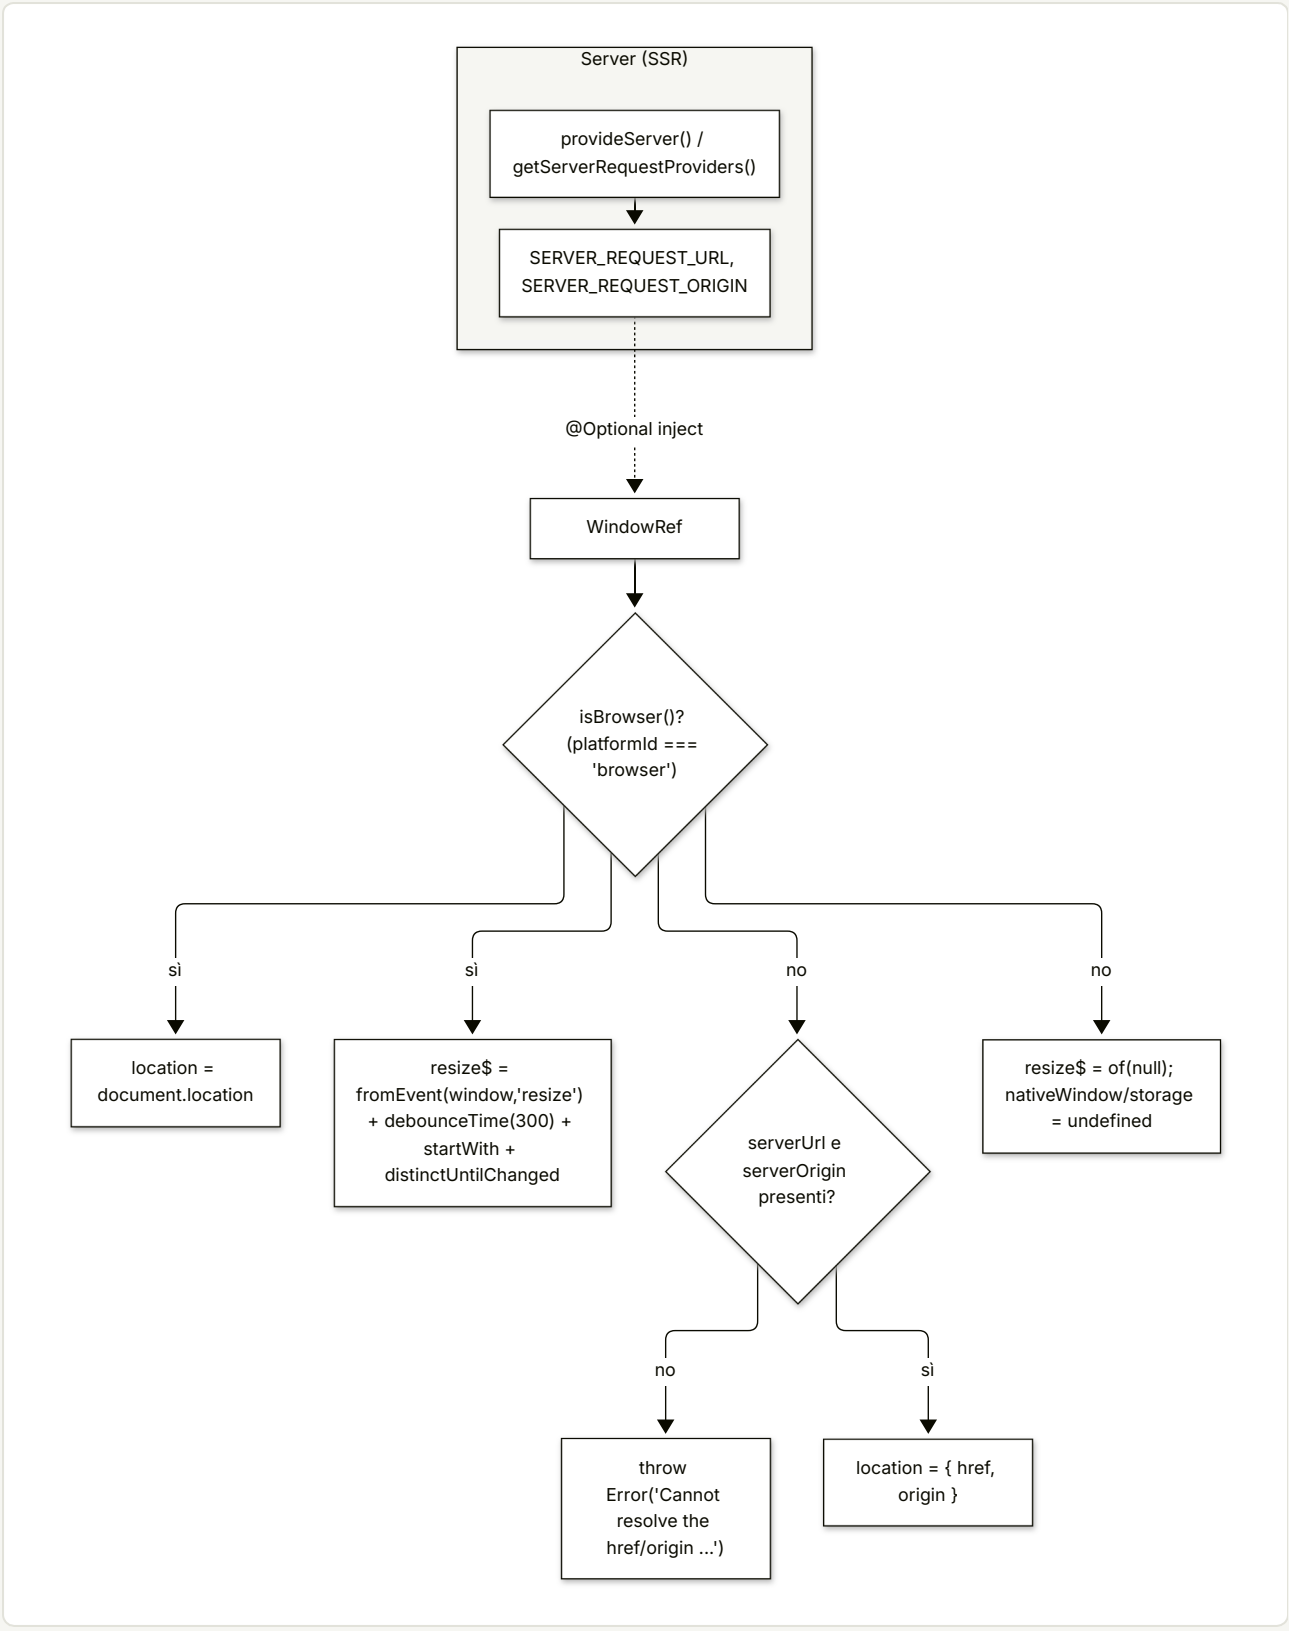
Riferimenti: cache e reset `core-libs/core/src/util/converter.service.ts:L39-L50`; lookup `core-libs/core/src/util/converter.service.ts:L52-L65`; `getMulti` `core-libs/core/src/lazy-loading/unified-injector.ts:L75-L95`; passthrough `core-libs/core/src/util/converter.service.ts:L80-L88`; catena `core-libs/core/src/util/converter.service.ts:L130-L137`.

4.3 `resolveApplicable`



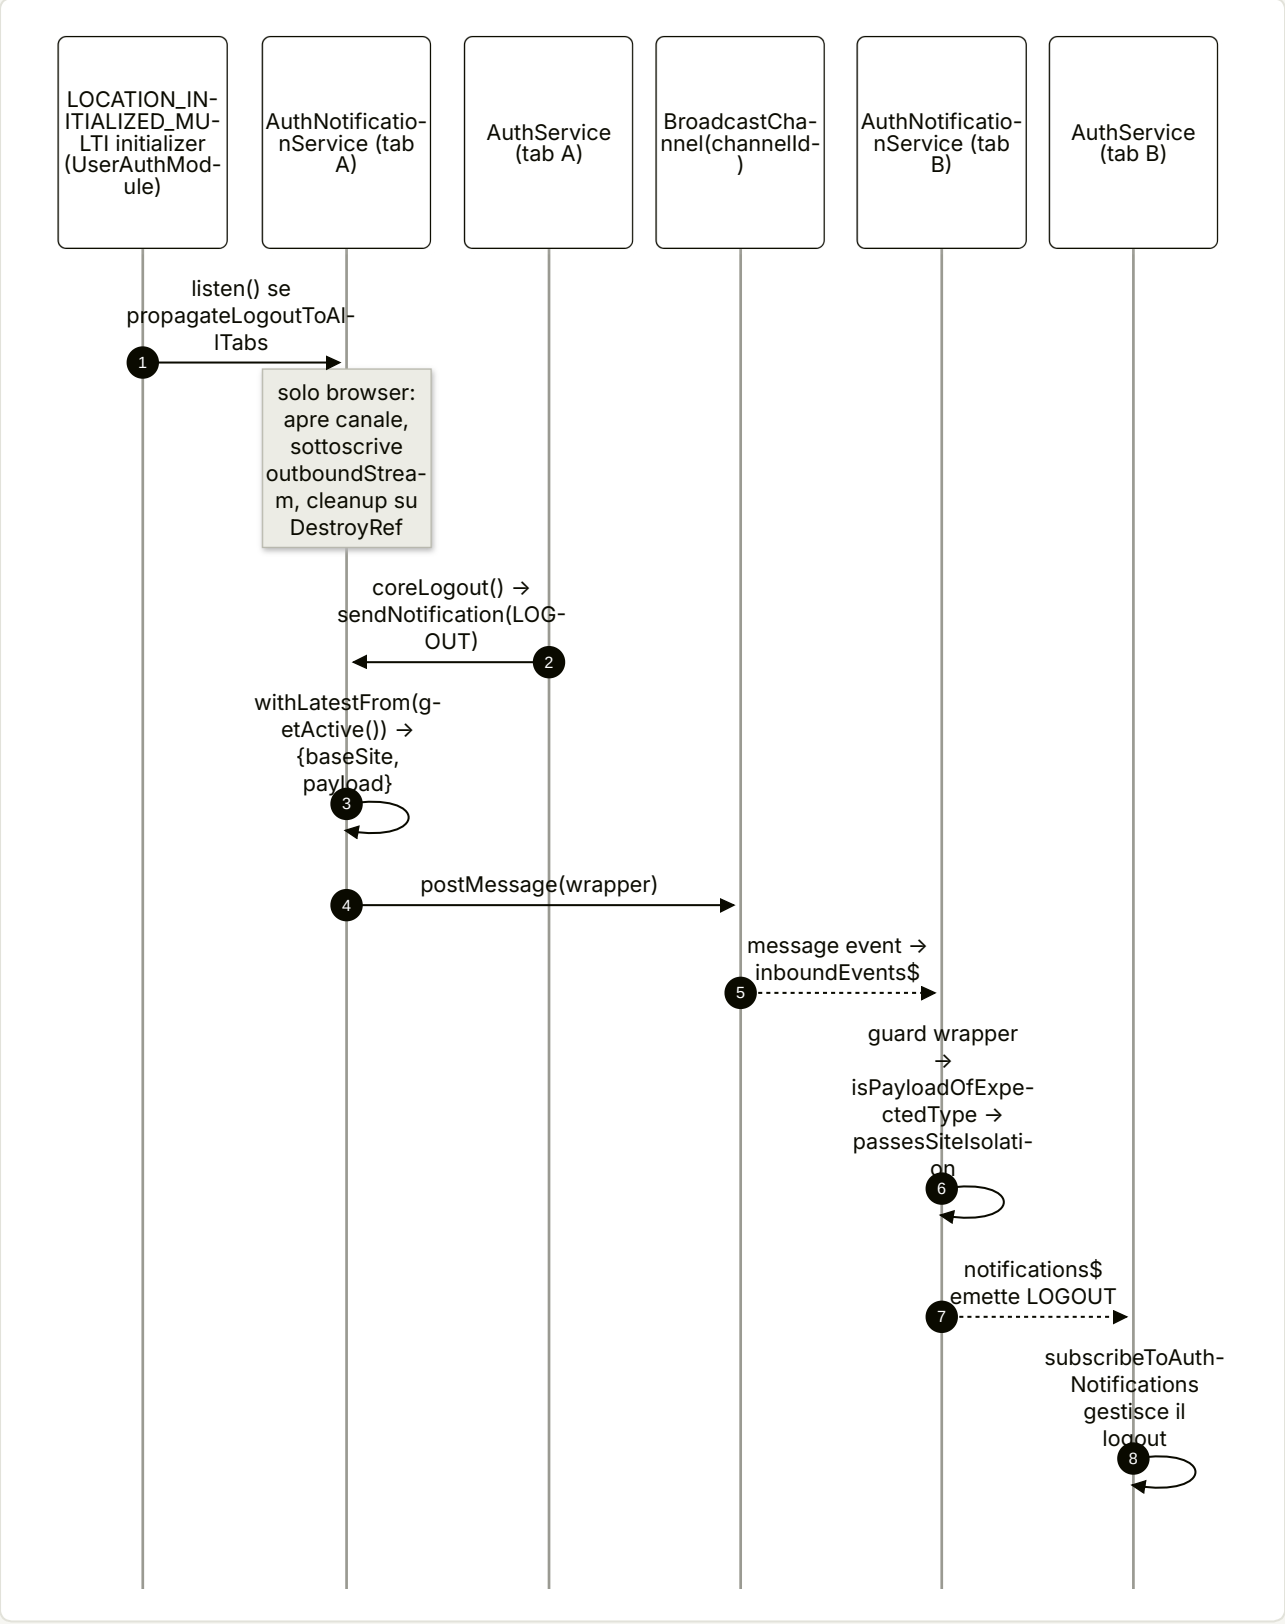
Riferimenti: `core-libs/core/src/util/applicable.ts:L63-L87`.

4.4 `WindowRef.location` e `resize$` tra browser e server



Riferimenti: `core-libs/setup/ssr/providers/ssr-providers.ts:L27-L37`, `core-libs/core/src/window/window-ref.ts:L19-L27`, `core-libs/core/src/window/window-ref.ts:L70-L107`.

4.5 Logout propagato tra tab



Riferimenti: core-libs/core/src/auth/user-auth/user-auth.module.ts:L85-L92, core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L60-L111, core-libs/core/src/auth/user-auth/facade/auth.service.ts:L195-L199, core-libs/core/src/auth/user-auth/facade/auth.service.ts:L240-L247.

5. Estratti di codice reale

5.1 `resolveApplicable`

core-libs/core/src/util/applicable.ts:L63-L87

```ts
export function resolveApplicable<T extends Applicable>(
  applicables: T[],
  matchParams: any[] = [],
  priorityParams: any[] = []
): T | undefined {
  const matchedApplicables = (applicables ?? []).filter(
    (applicable) => !applicable.hasMatch || applicable.hasMatch(...matchParams)
  );

  if (matchedApplicables.length < 2) {
    return matchedApplicables[0];
  }

  let lastPriority = -Infinity;
  return matchedApplicables.reduce((acc: T | undefined, curr: T) => {
    const currPriority = curr.getPriority
      ? curr.getPriority(...priorityParams)
      : Priority.NORMAL;
    if (lastPriority > currPriority) {
      return acc;
    }
    lastPriority = currPriority;
    return curr;
  }, undefined);
}
```

Si noti l'operatore `>` stretto: è ciò che fa vincere l'ultimo a parità di priorità.

5.2 `ConverterService`: reset cache, lookup, catena

core-libs/core/src/util/converter.service.ts:L38-L65

```ts
  constructor(protected unifiedInjector: UnifiedInjector) {
    // Clear cached converters when new injectors appear
    const cacheResetLogic = this.unifiedInjector.injectors$.pipe(
      tap(() => this.converters.clear())
    );

    this.subscriptions.add(cacheResetLogic.subscribe());
  }

  private converters: Map<
```

```
    InjectionToken<Converter<any, any>>,
    Converter<any, any>[]
  > = new Map();

  private getConverters<S, T>(
    injectionToken: InjectionToken<Converter<S, T>>
  ): Converter<S, T>[] | undefined {
    if (!this.converters.has(injectionToken)) {
      const converters = getLastValueSync(
        this.unifiedInjector.getMulti(injectionToken)
      );
      if (converters) {
        this.converters.set(injectionToken, converters);
      }
    }

    return this.converters.get(injectionToken);
  }
```

core-libs/core/src/util/converter.service.ts:L130-L137

```ts
  private convertSource<S, T>(
    source: S,
    injectionToken: InjectionToken<Converter<S, T>>
  ): T {
    return this.getConverters(injectionToken)?.reduce((target, converter) => {
      return converter.convert(source, target);
    }, undefined as any);
  }
```

5.3 tryNormalizeHttpError

core-libs/core/src/util/try-normalize-http-error.ts:L21-L58

```ts
export function tryNormalizeHttpError(
  error: HttpErrorResponse | HttpErrorModel | any,
  logger: LoggerService
): HttpErrorModel | Error {
  return normalizeHttpError(error, logger) ?? error;
}

// CXSPA-11104: Revise type to avoid redundant types - typescript:S6571
function normalizeHttpError(
  error: HttpErrorResponse | HttpErrorModel | any,
  logger: LoggerService
): HttpErrorModel | undefined {
  if (error instanceof HttpErrorModel) {
    return error;
```

```
  }

  if (error instanceof HttpErrorResponse) {
    const normalizedError = new HttpErrorModel();
    normalizedError.message = error.message;
    normalizedError.status = error.status;
    normalizedError.statusText = error.statusText;
    normalizedError.url = error.url;

    // include backend's error details
    if (Array.isArray(error.error.errors)) {
      normalizedError.details = error.error.errors;
    } else if (typeof error.error.error === 'string') {
      normalizedError.details = [
        {
          type: error.error.error,
          message: error.error.error_description,
        },
      ];
    }

    return normalizedError;
  }
```

5.4 backOff

core-libs/core/src/util/rxjs/back-off.ts:L39-L62

TS

```
export function backOff<T>(options?: BackOffOptions): OperatorFunction<T, T> {
  const shouldRetry = options?.shouldRetry ?? (() => true);
  const maxTries = options?.maxTries ?? 3;
  const delay = options?.delay ?? 300;

  return (source$) =>
    source$.pipe(
      // retries the source stream in case of an error.
      retry({
        delay: (attemptError: HttpErrorModel | Error, currentRetry) => {
          // if we've re-tried more than the maxTries, OR
          // if the source error is not the one we want to exponentially retry
          if (currentRetry > maxTries || !shouldRetry(attemptError)) {
            throw attemptError;
          }

          // exponential
          const exponent = currentRetry * currentRetry;
          // back-off
          return timer(exponent * delay);
```

```
        },
      })
    );
}
```

5.5 Due `backOff` in cascata in un adapter reale

feature-libs/order/occ/adapters/occ-order.adapter.ts:L91-L102

```ts
      .pipe(
        catchError((error) => {
          throw tryNormalizeHttpError(error, this.logger);
        }),
        backOff({
          shouldRetry: isJaloError,
        }),
        backOff({
          shouldRetry: isServerError,
          maxTries: DEFAULT_SERVER_ERROR_RETRIES_COUNT,
        }),
        this.converter.pipeable(ORDER_NORMALIZER)
```

5.6 `uniteLatest`

core-libs/core/src/util/rxjs/unite-latest.ts:L26-L47

```ts
export function uniteLatest<R extends Observables>(
  sources: R
): Observable<ReturnTypes<R>> {
  return defer(() => {
    let subNo = 0;
    const trigger = new Observable<void>((subscriber) => {
      const action = () => {
        subscriber.next();
        subscriber.complete();
      };

      if (subNo) {
        asapScheduler.schedule(action);
      } else {
        action();
      }
      subNo++;
    });
```

```
    return combineLatest(sources).pipe(audit(() => trigger));
  }) as any;
}
```

`audit` sottoscrive `trigger` a ogni valore che apre una finestra: la prima volta (`subNo === 0`) il trigger scatta subito, le volte successive scatta su `asapScheduler`, lasciando che le altre sorgenti "sincrone" aggiornino il valore prima dell'emissione.

5.7 `CombinedInjector.get`

core-libs/core/src/util/combined-injector.ts:L43-L71

TS

```
get(token: any, notFoundValue?: any, optional?: InjectOptions): any {
  if (optional && optional.self) {
    if (notFoundValue !== undefined) {
      return notFoundValue;
    }
    throw new Error(
      "CombinedInjector should be used as a parent injector / doesn't support self dependencies"
    );
  }

  for (const injector of this.complementaryInjectors) {
    // First we are resolving providers provided at Self level
    // in all complementary injectors...
    const service = injector.get(token, NOT_FOUND_SYMBOL, { self: true });
    if (service !== NOT_FOUND_SYMBOL) {
      return service;
    }
  }

  for (const injector of this.complementaryInjectors) {
    // next we try to resolve tokens from all levels
    const service = injector.get(token, NOT_FOUND_SYMBOL);
    if (service !== NOT_FOUND_SYMBOL) {
      return service;
    }
  }
  // ...and then fallback to main injector
  return this.mainInjector.get(token, notFoundValue);
}
```

5.8 `WindowRef.location` e `resize$`

core-libs/core/src/window/window-ref.ts:L70-L107

```ts
  get location(): Partial<Location> {
    if (this.isBrowser()) {
      return this.document.location;
    } else {
      if (!this.serverUrl) {
        throw new Error(
          'Cannot resolve the href as the SERVER_REQUEST_URL is undefined'
        );
      }
      if (!this.serverOrigin) {
        throw new Error(
          'Cannot resolve the origin as the SERVER_REQUEST_ORIGIN is undefined'
        );
      }
      return {
        href: this.serverUrl,
        origin: this.serverOrigin,
      };
    }
  }

  /**
   * Returns an observable for the window resize event and emits an event
   * every 300ms in case of resizing. An event is simulated initially.
   *
   * If there's no window object available (i.e. in SSR), a null value is emitted.
   */
  get resize$(): Observable<any> {
    if (!this.nativeWindow) {
      return of(null);
    } else {
      return fromEvent(this.nativeWindow, 'resize').pipe(
        debounceTime(300),
        startWith({ target: this.nativeWindow }),
        distinctUntilChanged()
      );
    }
  }
```

5.9 `ScriptLoader.embedScript` (corpo)

core-libs/core/src/util/script-loader.service.ts:L55-L93

```ts
    const isSSR = isPlatformServer(this.platformId);
    if ((callback || errorCallback) && isSSR) {
      return;
    }
```

```
  const source = params ? src + this.parseParams(params) : src;
  if (!isSSR && this.hasScript(source)) {
    return;
  }

  const script: HTMLScriptElement = this.document.createElement('script');
  script.src = source;
  script.async = true;
  script.defer = true;

  if (attributes) {
    Object.keys(attributes).forEach((key) => {
      // custom attributes
      if (
        key.startsWith('data-') ||
        (disableKeyRestriction && !(key in script))
      ) {
        script.setAttribute(key, attributes[key as keyof object]);
      } else {
        (script as any)[key] = attributes[key as keyof object];
      }
    });
  }

  if (callback) {
    script.addEventListener('load', callback);
  }
  if (errorCallback) {
    script.addEventListener('error', errorCallback);
  }

  placement === ScriptPlacement.HEAD
    ? this.document.head.appendChild(script)
    : this.document.body.appendChild(script);
```

5.10 JavaRegExpConverter.toJsRegExp

core-libs/core/src/util/java-reg-exp-converter/java-reg-exp-converter.ts:L42-L58

```ts
toJsRegExp(javaSyntax: string): RegExp | null {
  const parts = javaSyntax.match(this.EXTRACT_JAVA_REGEXP_MODIFIERS);
  if (!parts) {
    return null;
  }
  const [, , modifiers, jsSyntax] = parts;
  try {
    return new RegExp(jsSyntax, modifiers);
  } catch (error) {
```

```
      if (isDevMode()) {
        this.logger.warn(
          `WARNING: Could not convert Java regexp into Javascript. Original regexp: ${javaSyntax}
\nMessage: ${error}`
        );
      }
      return null;
    }
  }
```

5.11 `listen()` e `sendNotification()` della notifica cross-tab

core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L93-L120

TS

```
  listen(): void {
    if (!this.windowRef.isBrowser()) {
      return;
    }
    try {
      this.channel = new BroadcastChannel(this.channelId);
      this.channel.addEventListener('message', (event) =>
        this.inboundEvents$.next(event)
      );
      this.destroyRef.onDestroy(() => this.channel?.close());

      const sub = this.outboundStream.subscribe();
      this.destroyRef.onDestroy(() => sub.unsubscribe());
    } catch (err) {
      this.logger.warn(
        `Could not open ${this.channelId} channel: ${(err as Error)?.message ?? ''}`
      );
    }
  }

  /**
   * Sends `data` to other tabs. No-op when `listen()` was never called
   * (e.g. running on the server, or unsupported browser): the payload
   * is dropped silently.
   */
  sendNotification(data: T): void {
    this.outbound.next(data);
  }
```

5.12 Module augmentation, anche di un enum

feature-libs/subscription-billing/root/model/subscription-product.model.ts:L98-L110

```ts
declare module '@spartacus/core' {
  interface Product {
    sapSubscriptionTerm?: SubscriptionTerm;
    sapPricePlan?: PricePlan;
  }
}

declare module '@spartacus/core' {
  enum ProductScope {
    SUBSCRIPTION = 'subscription',
  }
}
(ProductScope as any)['SUBSCRIPTION'] = 'subscription';
```

6. Configurazione

Il capitolo non definisce chiavi di `Config` (quelle sono in 11). Le "manopole" sono parametri di funzione, default di classe e token:

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
BackOffOptions.maxTries	number	3	core-libs/core/src/util/rxjs/back-off.ts:L23-L24	core-libs/core/src/util/rxjs/back-off.ts:L41-L41
BackOffOptions.delay	number (ms)	300	core-libs/core/src/util/rxjs/back-off.ts:L26-L27	core-libs/core/src/util/rxjs/back-off.ts:L42-L42
BackOffOptions.shouldRetry	(err) => boolean	() => true	core-libs/core/src/util/rxjs/back-off.ts:L21-L21	core-libs/core/src/util/rxjs/back-off.ts:L40-L40
DEFAULT_SERVER_ERROR_RETRIES_COUNT	costante	2	core-libs/core/src/util/occ-http-error-handlers.ts:L30-L30	feature-libs/order/occ/adapters/occ-order.adapter.ts:L98-L101
DEFAULT_AUTHORIZATION_ERROR_RETRIES_COUNT	costante	2	core-libs/core/src/util/occ-http-error-handlers.ts:L31-L31	integration-libs/opf/payment/core/services/opf-payment-hosted-fields.service.ts:L119-L122
embedScript.placement	ScriptPlacement	HEAD	core-libs/core/src/util/script-loader.service.ts:L42-L42	core-libs/core/src/util/script-loader.service.ts:L91-L93
embedScript.disableKeyRestriction	boolean	undefined	core-libs/core/src/util/script-loader.service.ts:L43-L43	core-libs/core/src/util/script-loader.service.ts:L75-L75
B64EncodingOptions.urlSafe	boolean	undefined	core-libs/core/src/util/base64.ts:L7-L14	core-libs/core/src/util/base64.ts:L25-L25, core-libs/core/src/util/base64.ts:L35-L35

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN
`globToRegex(…, literalQuestionMark)`	`boolean`	`false`	`core-libs/core/src/util/glob-utils.ts:L38-L38`	`core-libs/core/src/util/glob-utils.ts:L39-L41`
`bufferDebounceTime(time)`	`number`	`0`	`core-libs/core/src/util/rxjs/buffer-debounce-time.ts:L11-L11`	`core-libs/core/src/util/rxjs/buffer-debounce-time.ts:L19-L19`
`isolateBySite` (cross-tab)	`boolean`	`true`	`core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L51-L51`	`core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L126-L126`
debounce di `WindowRef.resize$`	costante	`300` ms	`core-libs/core/src/window/window-ref.ts:L102-L102`	—
`SERVER_REQUEST_URL` / `SERVER_REQUEST_ORIGIN`	`InjectionToken<string>`	nessuno (opzionali in `WindowRef`)	`core-libs/core/src/util/ssr.tokens.ts:L12-L21`	`core-libs/core/src/window/window-ref.ts:L23-L24` (forniti in `core-libs/setup/ssr/providers/ssr-providers.ts:L29-L36`)
feature toggle `propagateLogoutToAllTabs`	`boolean`	vedi 42	—	`core-libs/core/src/auth/user-auth/user-auth.module.ts:L88-L88`

Nota: `OccCartAccessCodeAdapter` usa `maxTries: 2` letterale invece della costante (`feature-libs/cart/base/occ/adapters/occ-cart-access-code.adapter.ts:L42-L45`): cambiare la costante non lo influenza.

---

7. Commenti e note notevoli dal sorgente

- `// TODO(#11133): Consider throwing in SSR` su `nativeWindow`: oggi restituisce `undefined`, ma è stata valutata un'eccezione esplicita (`core-libs/core/src/window/window-ref.ts:L42-L42`).
- `// https://github.com/angular/angular/issues/20351` sul parametro `document: any` del costruttore di `WindowRef`: spiega perché il tipo è `any` e poi viene fatto il cast a `Document` (`core-libs/core/src/window/window-ref.ts:L20-L20`).
- JSDoc di `JavaRegExpConverter.toJsRegExp`: "**CAUTION!** Not all features and modifiers of Java regexps are valid in Javascript!" (`core-libs/core/src/util/java-reg-exp-converter/java-reg-exp-converter.ts:L35-L36`).
- JSDoc di `getLastValueSync`: "Should be used with caution, as it's not a legitimate way for getting value from the observable." (`core-libs/core/src/util/rxjs/get-last-value-sync.ts:L13-L15`).
- JSDoc di `backOff`: cita come fonte la guida Angular "practical observable usage / exponential backoff" e il tag `@returns` è troncato ("or the") (`core-libs/core/src/util/rxjs/back-off.ts:L34-L37`).
- JSDoc di `resolveApplicable`: "the applicable that was provided later wins" (`core-libs/core/src/util/applicable.ts:L47-L62`).
- JSDoc di `FormUtils.deepUpdateValueAndValidity`: la funzione potrà essere rimossa quando Angular la implementerà nativamente (angular/angular#6170) (`core-libs/storefront/utils/form-utils.ts:L24-L25`).

- `// CXSPA-11104: Revise type to avoid redundant types - typescript:S6571` su `normalizeHttpError` (core-libs/core/src/util/try-normalize-http-error.ts:L28-L28).
- `// TODO: Simplify with converter` su `AddressValidation.errors`, che ha la forma annidata `{ errors: ErrorModel[] }` (core-libs/core/src/model/address.model.ts:L71-L71).
- `// TODO: Upgrade model when Breadcrumbs will be finally used in project` su `CmsBreadcrumbsComponent` (core-libs/core/src/model/cms.model.ts:L167-L168).
- `// TODO(#8875): Do we need it here?` su `EntitiesModel` (core-libs/core/src/model/misc.model.ts:L66-L66) e `// TODO(#8876): Should we simplify the models only for the fields required by the B2B checkout?` in testa ai modelli B2B (core-libs/core/src/model/org-unit.model.ts:L10-L10).
- `// CHECK SONAR` in coda a `object-comparison-utils.ts` (core-libs/core/src/util/object-comparison-utils.ts:L95-L95).
- Il commento in `fromUrlSafe` dice "'_' to '+'" ma il codice converte _ in `/`: il codice è corretto, il commento no (core-libs/core/src/util/base64.ts:L46-L47).
- `glob-utils.ts` porta il copyright "Google LLC. http://angular.io/license" (core-libs/core/src/util/glob-utils.ts:L1-L7).
- Nessun `@deprecated` né `FIXME` nei 57 file del capitolo (verifica grep riportata nel dossier).

8. Extension point

EXTENSION POINT	COME SI ESTENDE	DEFINIZIONE	EXPORT PUBBLICO	RICETTA
`Applicable` / `Priority` / `resolveApplicable`	implementare `hasMatch`/`getPriority` in un nuovo provider (es. resolver, handler); usare `Priority.HIGH` o `NORMAL + n` per vincere sul default	core-libs/core/src/util/applicable.ts:L7-L87	core-libs/core/src/util/index.ts:L7-L7	50 — Ricette DI, 52 — meta resolver
`Converter<S,T>` su un `InjectionToken` (multi)	aggiungere un converter con `multi: true`: riceverà `(source, target)` dopo quelli già registrati	core-libs/core/src/util/converter.service.ts:L21-L35	core-libs/core/src/util/index.ts:L11-L11	52 — Ricette OCC, converter
`ConverterService`	servizio root; normalmente si usa, non si sostituisce	core-libs/core/src/util/converter.service.ts:L32-L142	idem	52
Predicati `isJaloError` / `isServerError` / `isAuthorizationError` + `backOff`	riusabili negli adapter custom come `shouldRetry`	core-libs/core/src/util/occ-http-error-handlers.ts:L12-L31, core-libs/core/src/util/rxjs/back-off.ts:L39-L62	core-libs/core/src/util/index.ts:L7-L29, core-libs/core/src/util/rxjs/index.ts:L7-L7	52

EXTENSION POINT	COME SI ESTENDE	DEFINIZIONE	EXPORT PUBBLICO	RICETTA
`AbstractBrowserTabNotificationService<T>`	sottoclasse con `channelId`, `isPayloadOfExpectedType`, opz. `isolateBySite = false`; chiamare `listen()` (es. da un initializer)	core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L49-L135	core-libs/core/src/util/index.ts:L9-L9	50
`WindowRef`	iniettarlo invece di usare `window`; sostituibile/mockabile via DI	core-libs/core/src/window/window-ref.ts:L13-L108	core-libs/core/src/window/index.ts:L7-L7	50
`SERVER_REQUEST_URL`, `SERVER_REQUEST_ORIGIN`	fornirli in un server custom se non si usa `provideServer()`	core-libs/core/src/util/ssr.tokens.ts:L12-L21	core-libs/core/src/util/index.ts:L24-L24	50
`ScriptLoader`	classe root con metodi `public` (`parseParams` è `private`)	core-libs/core/src/util/script-loader.service.ts:L15-L122	core-libs/core/src/util/index.ts:L23-L23	50
`JavaRegExpConverter`, `GlobService`	servizi root sostituibili via DI	core-libs/core/src/util/java-reg-exp-converter/java-reg-exp-converter.ts:L10-L59, core-libs/core/src/util/glob.service.ts:L10-L33	core-libs/core/src/util/index.ts:L13-L16	51 — route custom
Modelli aumentabili (`Address`, `B2BUnit`, `B2BUser`, `Product`, `Price`, `Stock`, `Facet`, `ProductSearchPage`, `OccHttpErrorType`, …)	`declare module '@spartacus/core' { interface Product { ... } }`	core-libs/core/public_api.ts:L38-L58	blocco `AUGMENTABLE_TYPES_START/END`	52 — campi OCC aggiuntivi, 53
Tutti gli altri modelli di `model/`	stessa tecnica di augmentation	core-libs/core/src/model/index.ts:L7-L20	core-libs/core/public_api.ts:L26-L26	52
`FormUtils`, `getAddressNumbers`	utility da riusare nei componenti custom	core-libs/storefront/utils/form-utils.ts:L16-L53, core-libs/storefront/utils/address-number-utils.ts:L12-L33	core-libs/storefront/utils/index.ts:L7-L9	51
Non extension point: `CombinedInjector`, `glob-utils`, `bufferDebounceTime`, `unused.model.ts`	interni: non importabili da `@spartacus/core`	core-libs/core/src/util/combined-injector.ts:L27-L72, core-libs/core/src/util/rxjs/index.ts:L7-L11	—	54 — API pubblica vs interna

Uno schizzo (illustrativo, non presente nel repo) di augmentation + converter, usando solo simboli pubblici (`Product`, `Converter`, `Occ`, `PRODUCT_NORMALIZER`); la ricetta completa con la registrazione del provider è in 52:

```ts
// esempio illustrativo
declare module '@spartacus/core' {
  interface Product {
    myBadge?: string;
  }
}

@Injectable()
export class MyBadgeNormalizer implements Converter<Occ.Product, Product> {
  convert(source: Occ.Product, target?: Product): Product {
    target = target ?? { ...(source as any) }; // il primo della catena riceve undefined
    target.myBadge = (source as any).badge;
    return target;
  }
}
```

DA VERIFICARE: lo schizzo non è compilato (node_modules assente); `Occ` e `PRODUCT_NORMALIZER` sono simboli pubblici di core ma la loro firma va controllata nella ricetta 52.

---

9. Trappole, casi limite, comportamenti controintuitivi

1. **A parità di priorità vince l'ultimo.** `resolveApplicable` scarta il corrente solo se `lastPriority > currPriority`: l'ordine dei provider conta, e un handler custom con la stessa priorità del default vince solo se registrato dopo (core-libs/core/src/util/applicable.ts:L81-L85).
2. **Con un solo match** `getPriority` **non viene neppure chiamato** (core-libs/core/src/util/applicable.ts:L72-L74): un breakpoint in `getPriority` non scatta.
3. **Nessuna cache dei "nessun converter".** `getConverters` mette in cache solo valori definiti; per un token senza provider `getMulti` non emette (filtra gli array vuoti) e ogni chiamata rifà il lookup (core-libs/core/src/util/converter.service.ts:L55-L62, core-libs/core/src/lazy-loading/unified-injector.ts:L82-L92).
4. `pipeable` **decide al momento della creazione dell'operatore**, non a ogni emissione: se la pipe è costruita prima che un modulo lazy porti il primo converter del token, quella pipe resta passthrough (inferenza dalla struttura di core-libs/core/src/util/converter.service.ts:L83-L87).
5. **Il primo converter riceve** `target === undefined` (core-libs/core/src/util/converter.service.ts:L134-L136): i converter "aggiuntivi" devono gestirlo, perché a priori non sanno se sono primi.
6. `backOff` **ritenta qualsiasi errore per default** (`shouldRetry = () => true`, core-libs/core/src/util/rxjs/back-off.ts:L40-L40), compresi 4xx non transitori. Inoltre con due `backOff` in cascata (§5.5) il secondo ri-sottoscrive tutta la catena a monte, primo `backOff` compreso, il cui contatore riparte (inferenza dalla semantica di `retry`).
7. `tryNormalizeHttpError` **e** `error.error` **nullo.** Il codice accede a `error.error.errors` senza optional chaining (core-libs/core/src/util/try-normalize-http-error.ts:L45-L47): un `HttpErrorResponse` con `error` `null`/`undefined` farebbe lanciare un `TypeError`. DA VERIFICARE: inferenza dal codice, non confermata da spec o esecuzione.

8. **Fuori dev mode niente log**: per errori non HTTP `tryNormalizeHttpError` restituisce silenziosamente l'originale (core-libs/core/src/util/try-normalize-http-error.ts:L59-L65), che potrebbe non essere serializzabile.
9. `getLastValueSync` **su sorgenti asincrone restituisce** `undefined` (core-libs/core/src/util/rxjs/get-last-value-sync.ts:L19-L23).
10. **Simboli non pubblici.** `bufferDebounceTime`, `globToRegex`/`getGlobMatcher`/`processGlobPatterns` e `CombinedInjector` non si importano da `@spartacus/core` (core-libs/core/src/util/rxjs/index.ts:L7-L11, core-libs/core/src/util/index.ts:L7-L29).
11. `CombinedInjector` **e** `@Self`**.** Con `{ self: true }` e senza `notFoundValue` lancia (core-libs/core/src/util/combined-injector.ts:L44-L51); inoltre ignora le altre `InjectOptions` (`optional`, `skipSelf`, `host`) e al main injector passa solo `notFoundValue` (core-libs/core/src/util/combined-injector.ts:L43-L70).
12. `isKeyInvalid` **lancia invece di restituire un boolean**, nonostante il nome (core-libs/core/src/util/is-key-invalid.ts:L17-L27).
13. **Glob "sporchi".** `globToRegex` escapa solo `.`, `+`, `*`, `?`: `(`, `[`, `$`, `^`, `|`, `{` restano metacaratteri attivi (core-libs/core/src/util/glob-utils.ts:L12-L24). Nei pattern di routing `?` è sempre un wildcard di un carattere non `/` (core-libs/core/src/util/glob-utils.ts:L97-L97). E `GlobService.getValidator` duplica `getGlobMatcher`: modificarne uno non cambia l'altro (core-libs/core/src/util/glob.service.ts:L17-L32, core-libs/core/src/util/glob-utils.ts:L71-L86).
14. **Modificatori Java senza equivalente JS** (es. `x`) fanno fallire `new RegExp` → `null`, e il pattern viene trattato come non matchante perché `?.test` dà `undefined` (core-libs/core/src/util/java-reg-exp-converter/java-reg-exp-converter.ts:L47-L57, core-libs/core/src/site-context/config/config-loader/site-context-config-initializer.ts:L102-L102). In produzione non c'è neanche il warning.
15. `ScriptLoader` **in SSR** aggiunge lo script al DOM server (quindi all'HTML) se non ci sono callback, e salta il controllo duplicati: chiamate ripetute possono duplicarlo (core-libs/core/src/util/script-loader.service.ts:L55-L63). `parseParams` usa `encodeURI`, che non codifica `&`, `=`, `?`, `#` (core-libs/core/src/util/script-loader.service.ts:L114-L117); `hasScript` interpola `src` in un selettore CSS senza escaping (core-libs/core/src/util/script-loader.service.ts:L99-L101).
16. `WindowRef.location` **in SSR** lancia se i token non sono forniti e restituisce solo `href` e `origin`: `pathname`, `search`, `hash` sono `undefined` (core-libs/core/src/window/window-ref.ts:L74-L88).
17. `resize$` **e** `distinctUntilChanged()`: confronta per riferimento e gli `Event` sono sempre oggetti nuovi, quindi di fatto non filtra nulla dopo il valore iniziale (inferenza da core-libs/core/src/window/window-ref.ts:L101-L105).
18. **Notifiche cross-tab perse.** `sendNotification` prima di `listen()` (o in SSR) scarta silenziosamente; e poiché `outboundStream` usa `withLatestFrom(getActive())`, anche i messaggi inviati prima che il base site attivo abbia emesso vanno persi (seconda parte: inferenza dalla semantica di `withLatestFrom`) (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L60-L67, core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L113-L120).
19. `deepEqualObjects` **e oggetti senza proprietà proprie.** Due `Date` diverse risultano uguali; `NaN` non è uguale a se stesso (inferenza da core-libs/core/src/util/object-comparison-utils.ts:L46-L75). `indexOfFirstOccurrence` restituisce `undefined`, non `-1` (core-libs/core/src/util/object-comparison-utils.ts:L86-L92).
20. **Offset timezone frazionari negativi.** Per UTC−03:30 (`offset = -210`) `Math.floor(-3.5) = -4` e `-210 % 60 = -30`, producendo `-04:-30` (core-libs/core/src/util/time-utils.ts:L17-L23). DA VERIFICARE: inferenza aritmetica, non confermata da spec.
21. `TestingTimeUtils` **senza** `try/finally`: se la callback lancia, `Date.prototype` resta patchato per i test successivi; ed è esportato nell'API pubblica di produzione (core-libs/core/src/util/testing-time-utils.

ts:L8-L20, core-libs/core/src/util/index.ts:L25-L25).

22. `FormUtils` **e form tipizzati.** Usa `instanceof UntypedFormGroup/UntypedFormArray`, ma in Angular 21 quei valori runtime sono gli stessi costruttori di `FormGroup`/`FormArray`, quindi funziona anche con form tipizzati e `FormRecord` (core-libs/storefront/utils/form-utils.ts:L37-L46, angular:packages/forms/src/model/form_group.ts:L706-L706, angular:packages/forms/src/model/form_group.ts:L739-L739, angular:packages/forms/src/model/form_array.ts:L584-L584).
23. **Tipi pubblici che usano tipi non pubblici.** `CustomerCouponSearchResult` e `ProductInterestSearchResult` usano `Pagination`/`Sort` di `unused.model.ts`, che non sono importabili per nome (core-libs/core/src/model/index.ts:L7-L20, core-libs/core/src/model/customer-coupon.model.ts:L27-L31). Non confonderli con `PaginationModel`/`SortModel`.
24. **Dipendenza circolare di tipo**: `misc.model.ts` importa `B2BUnit` da `'.'` (il barrel), mentre `org-unit.model.ts` importa `User` da `misc.model` (core-libs/core/src/model/misc.model.ts:L7-L7, core-libs/core/src/model/org-unit.model.ts:L8-L8).
25. **Augmentation di enum = solo tipo**: serve anche l'assegnazione runtime (feature-libs/subscription-billing/root/model/subscription-product.model.ts:L105-L110).
26. `CmsBannerCarouselEffect.CURTAIN` **vale** `'CURTAINX'` (core-libs/core/src/model/cms.model.ts:L128-L128); e molti flag CMS sono stringhe `'true'`/`'false'`, con `otherProperties?: any` (core-libs/core/src/model/cms.model.ts:L10-L10, core-libs/core/src/model/cms.model.ts:L219-L224): nei componenti servono conversioni esplicite.

---

10. Come fare debug

- **"Il mio converter non viene applicato".** Verificare che sia registrato con `multi: true` sullo **stesso** token (altrimenti `getMulti` lancia `Multi-providers mixed with single providers`, core-libs/core/src/lazy-loading/unified-injector.ts:L75-L95). Se è in un modulo lazy, controllare quando viene costruita la pipe che usa `pipeable` (trappola 4). Un breakpoint in `convertSource` (core-libs/core/src/util/converter.service.ts:L134-L136) mostra l'elenco effettivo e l'ordine dei converter.
- **"Viene scelto l'handler/resolver sbagliato".** Breakpoint nel `reduce` di `resolveApplicable` (core-libs/core/src/util/applicable.ts:L77-L86) e ispezione di `matchedApplicables`: si vede subito chi passa `hasMatch` e con quale priorità. Ricordare che a parità vince l'ultimo.
- **Retry inattesi o assenti.** Nella tab Network del browser, i retry di `backOff` appaiono come richieste ripetute a 300 ms, 1,2 s, 2,7 s. Verificare il `shouldRetry` passato e lo `status`/`details` dell'`HttpErrorModel` (core-libs/core/src/util/occ-http-error-handlers.ts:L12-L28).
- **Errore non serializzabile nello store.** Se nelle action NgRx compare un `HttpErrorResponse` invece di un `HttpErrorModel`, l'adapter non usa `tryNormalizeHttpError`; in dev mode, se è stato passato un errore non HTTP, la console mostra "Error passed to tryNormalizeHttpError is not HttpErrorResponse instance" (core-libs/core/src/util/try-normalize-http-error.ts:L59-L65).
- **SSR: "Cannot resolve the href as the SERVER_REQUEST_URL is undefined".** Il server non fornisce i token: usare `provideServer()` o `getServerRequestProviders()` (core-libs/setup/ssr/providers/ssr-providers.ts:L27-L37, core-libs/setup/ssr/providers/ssr-providers.ts:L53-L65).
- **Base site non riconosciuto dall'URL.** In dev mode cercare in console "WARNING: Could not convert Java regexp into Javascript" (core-libs/core/src/util/java-reg-exp-converter/java-reg-exp-converter.ts:L51-L55); poi provare a mano `new RegExp(...)` con i flag estratti.
- **Notifiche cross-tab.** Verificare che `listen()` sia stato chiamato (per l'auth: toggle `propagateLogoutToAllTabs`, core-libs/core/src/auth/user-auth/user-auth.module.ts:L85-L92), cercare il

warning "Could not open ... channel" (core-libs/core/src/util/browser-tab-notification/abstract-browser-tab-notification.service.ts:L106-L109) e confrontare il `baseSite` del wrapper con quello attivo nell'altra tab.

- **Script duplicati nell'HTML SSR.** Ispezionare il sorgente della pagina (non il DOM): `ScriptLoader` in SSR non deduplica (trappola 15).
- **Test che dipendono dal fuso orario.** Usare `TestingTimeUtils.fakeDateTimezoneOffset` (core-libs/core/src/util/testing-time-utils.ts:L7-L21), ricordando che non ripristina se la callback lancia.

---

11. Domande di autoverifica

1. **Due `PageMetaResolver` matchano la stessa pagina ed entrambi restituiscono `Priority.NORMAL`. Quale viene scelto?** L'ultimo nell'ordine dei provider: il `reduce` scarta il corrente solo se `lastPriority > currPriority`. — core-libs/core/src/util/applicable.ts:L76-L86
2. **Cosa restituisce `ConverterService.convert(source, token)` se per `token` non è registrato alcun converter?** Lo stesso `source`, con un cast di tipo; `pipeable` in quel caso è un operatore identità. — core-libs/core/src/util/converter.service.ts:L106-L112, core-libs/core/src/util/converter.service.ts:L80-L88
3. **Perché un converter registrato in un modulo lazy viene visto dal `ConverterService` root?** Perché il servizio legge i converter da `UnifiedInjector.getMulti` (che aggrega tutti gli injector) e svuota la cache a ogni emissione di `injectors$`. — core-libs/core/src/util/converter.service.ts:L39-L44, core-libs/core/src/util/converter.service.ts:L52-L65
4. **Con le opzioni di default, quanti retry fa `backOff` e quanto attende in totale?** 3 retry, con attese 300 + 1200 + 2700 = 4200 ms, perché il primo `currentRetry` passato da `retry` di RxJS 7.8 vale 1. — core-libs/core/src/util/rxjs/back-off.ts:L39-L61, deps:rxjs-7.8.2/package/dist/cjs/internal/operators/retry.js:L34-L34
5. **Perché `HttpErrorModel` è una classe e non un'interfaccia?** Il sorgente non lo motiva; di fatto, essendo una classe, `normalizeHttpError` può riconoscerla con `instanceof` e restituirla invariata. — core-libs/core/src/model/misc.model.ts:L100-L106, core-libs/core/src/util/try-normalize-http-error.ts:L33-L35
6. **Da dove prende i `details` `tryNormalizeHttpError` per una risposta d'errore OAuth?** Se `error.error.error` è una stringa, crea un unico dettaglio `{ type: error, message: error_description }`. — core-libs/core/src/util/try-normalize-http-error.ts:L44-L54
7. **Cosa succede leggendo `windowRef.location.pathname` durante il rendering SSR?** Si ottiene `undefined` (in SSR `location` ha solo `href` e `origin`), oppure un'eccezione se `SERVER_REQUEST_URL`/`SERVER_REQUEST_ORIGIN` non sono forniti. — core-libs/core/src/window/window-ref.ts:L70-L89
8. **Perché in SSR `ScriptLoader.embedScript` con una `callback` non fa nulla?** Perché in quel caso esce subito: `if ((callback || errorCallback) && isSSR) return;`. — core-libs/core/src/util/script-loader.service.ts:L55-L58
9. **Si può importare `bufferDebounceTime` o `CombinedInjector` da `@spartacus/core`?** No: `bufferDebounceTime` non è nel barrel `util/rxjs/index.ts`, `CombinedInjector` non è riesportato da alcun barrel. — core-libs/core/src/util/rxjs/index.ts:L7-L11, core-libs/core/src/util/index.ts:L7-L29
10. **Come aggiunge subscription-billing il valore `SUBSCRIPTION` all'enum `ProductScope`, e perché non basta `declare module`?** Con `declare module '@spartacus/core' { enum ProductScope { SUBSCRIPTION = 'subscription' } }` più l'assegnazione runtime `(ProductScope as any)['SUBSCRIPTION'] =`

`'subscription'`, perché l'augmentation agisce solo sul tipo. — `feature-libs/subscription-billing/root/model/subscription-product.model.ts:L98-L110`

---

1. A cosa serve e perché esiste

`projects/storefrontapp` è l'applicazione Angular con cui il team Spartacus sviluppa, prova e collauda le librerie del monorepo. Non è un'app "di esempio" nel senso di un template da copiare: è un banco di prova che deve poter accendere **qualunque** combinazione di librerie (B2C, B2B, integrazioni CDC/CDS/OPF/S4/...) a partire dalla stessa base di codice, deve essere guidabile dai test e2e (Cypress e SSR) e deve esercitare quotidianamente i percorsi di codice più recenti. Il codice stesso lo dichiara in più punti:

- il root component "belongs to the example app, not Spartacus libraries" (`projects/storefrontapp/src/app/app.component.ts:L10-L19`);
- `privateProviders` sono "used only in our example Storefrontapp for testing purposes. CAUTION: IT IS NOT MEANT FOR CUSTOMERS' APPLICATIONS!" (`projects/storefrontapp/src/app/private/private.providers.ts:L14-L19`);
- la scelta del canale B2B/B2C "is enabled only in our repo via a special environment variable at build time. In customers' applications, either B2B or B2C configuration is used, which is decided at the installation time" (`projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L33-L42`).

Leggere la demo serve quindi a due cose diverse:

1. **Capire come si assembla un'app Spartacus reale**: entry point standalone browser/server, `AppModule` che importa `SpartacusModule`, la triade *BaseStorefront + Features + Configuration*, i `*FeatureModule` con `featureModules` lazy, `server.ts` con Express e l'engine ottimizzato. La struttura ricalca quella che genera `ng add @spartacus/schematics` (vedi il commento su `ExternalRoutesModule`, "is added by default schematics", `projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L244-L247`).
2. **Distinguere ciò che è solo del repo**: il sistema di flag di build `CX_*` iniettati da un plugin esbuild custom, `env-cmd` con 26 ambienti, `TestConfigModule` guidato da cookie, i test outlet, i feature toggle tutti `true` imposti da ESLint. Tutto questo **non** va riprodotto in un progetto cliente.

Questo capitolo non ripete ciò che è trattato altrove:

- l'ordine di inizializzazione (`bootstrapApplication` → `ENVIRONMENT_INITIALIZER` → `APP_INITIALIZER` → navigazione iniziale) è in 10 — Bootstrap e ordine di inizializzazione: qui ci fermiamo a *quali* provider la demo registra e *in che ordine* entrano nell'injector;
- l'interno di `OptimizedSsrEngine` (timeout, cache, concorrenza, fallback CSR) è in 39 — SSR ottimizzato: qui vediamo come `server.ts` lo configura;
- il meccanismo dei feature toggle è in 42 — Feature toggle e deprecazioni: qui vediamo come la demo li accende tutti;
- `ConfigChunk`/`deepMerge` sono in 11 — Configurazione, `featureModules` e `FeatureModulesService` in 12 — Feature module e lazy loading.

2. Mappa dei file

PATH	RUOLO

`package.json` (root)	script `build`, `start*`, `build:ssr*`, `serve:ssr*`, `dev:ssr`, `prerender`

3. Come funziona passo per passo

3.1 Dalla shell al bundle: i flag di build

La demo è compilata in varianti diverse senza toccare il codice. Il meccanismo ha cinque anelli.

(a) `env-cmd` **carica ambienti nominati.** Lo script `build` è `env-cmd --no-override -e dev,b2c,$SPA_ENV -- nx run storefrontapp:build`; `start` usa gli stessi ambienti con `nx serve … --configuration=development`, e `start:b2b` sostituisce `b2c` con `b2b` (package.json:L16-L16, package.json:L133-L134). Gli ambienti stanno in `.env-cmdrc`: `dev` imposta solo `CX_BASE_URL`, `b2c` imposta `CX_B2B: "false"` e `CX_CDS: "false"`, `b2b` solo `CX_B2B: "true"` (`.env-cmdrc:L2-L4`, `.env-cmdrc:L51-L57`). Alcuni ambienti implicano B2B: `cpq`, `s4om` (B2B + S4OM + RDD + PDF invoices), `s4-service`, `punchout` (`.env-cmdrc:L42-L46`, `.env-cmdrc:L58-L64`, `.env-cmdrc:L96-L104`). La variabile di shell `SPA_ENV` permette di accodare un ambiente extra senza scrivere un nuovo script.

> DA VERIFICARE: la semantica precisa di `env-cmd -e a,b,c` (gli ambienti successivi sovrascrivono i precedenti) e di `--no-override` (non sovrascrive variabili già presenti nella shell) è dedotta dall'uso, es. `build:cds:ssr` con `-e dev,b2c,cds` dove `b2c` mette `CX_CDS: "false"` e `cds` lo riporta a `"true"` (package.json:L161-L161, `.env-cmdrc:L20-L22`). Il pacchetto `env-cmd` non è disponibile né in `/tmp/deps` né in `node_modules`.

(b) Nx esegue un builder esbuild personalizzato. Il target `build` usa `@angular-builders/custom-esbuild:application` con `plugins: ["./projects/storefrontapp/esbuild/plugins.ts"]` (projects/storefrontapp/project.json:L9-L13).

(c) Il plugin raccoglie le `CX_*`**.** `resolve-env-plugin` scorre `process.env`, tiene solo le chiavi con prefisso `CX_`, converte `'true'`/`'false'` in booleani e imposta `build.initialOptions.define['buildProcess.env']` al JSON risultante; stampa `env=` in console (projects/storefrontapp/esbuild/plugins.ts:L10-L31). Un secondo plugin, `filter-warnings`, elimina dai warning di esbuild quelli con "no side effects", "[ignored-bare-import]" e "is not ESM" (projects/storefrontapp/esbuild/plugins.ts:L34-L46).

(d) TypeScript conosce `buildProcess` **come globale.** `build.process.env.d.ts` dichiara `declare var buildProcess: BuildProcess` con l'interfaccia `Env` dei 19 `CX_*` (projects/storefrontapp/src/environments/models/build.process.env.d.ts:L7-L11, projects/storefrontapp/src/environments/models/build.process.env.d.ts:L13-L33); il file è incluso esplicitamente nei `files` di `tsconfig.app.json` (projects/storefrontapp/tsconfig.app.json:L12-L17).

(e) `environment.ts` **traduce le variabili in flag.** In sviluppo ogni flag è `buildProcess.env.CX_* ?? false`, `occBaseUrl` è `CX_BASE_URL` e `occApiPrefix` è fisso `'/occ/v2/'` (projects/storefrontapp/src/environments/environment.ts:L22-L44). La configurazione `production` del build sostituisce il file con `environment.prod.ts` tramite `fileReplacements` (projects/storefrontapp/project.json:L157-L162), che ha `production: true` e flag **senza** `?? false`, tranne `myAccountV2` (projects/storefrontapp/src/environments/environment.prod.ts:L9-L31). L'interfaccia `Environment` ha 23 campi: `production`, `occBaseUrl`, `occApiPrefix`, opzionali `mediaBaseUrl`/`mediaApiPrefix` e 18 flag booleani (projects/storefrontapp/src/environments/models/environment.model.ts:L7-L31).

I flag diventano **struttura** a import-time dei moduli ES, prima ancora che Angular parta:

- `spartacus-features.module.ts` costruisce l'array di modulo `featureModules`: con `b2b` aggiunge 7 moduli B2B, altrimenti `PickupInStoreFeatureModule`; poi un `if` per ciascuno di `cdc`, `s4Service`, `cds`, `digitalPayments`, `epdVisualization`, `pdfInvoices`, `opps`, `s4om`, `opf`, `punchout`, `segmentRefs`, `requestedDeliveryDate`, `estimatedDeliveryDate`, `omf`, `cpq` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L115-L175);
- il decoratore `@NgModule({ imports: [..., ...featureModules] })` "congela" la lista (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L285-L285);
- `spartacus-configuration.module.ts` sceglie i provider di canale con un ternario su `environment.b2b` (projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L40-L42);
- ogni wrapper module lazy costruisce il proprio array `extensions` (§3.5).

> DA VERIFICARE: se esbuild, grazie al `define` di `buildProcess.env` come oggetto JSON, faccia constant-folding di `buildProcess.env.CX_B2B` ed elimini i rami morti (e quindi i moduli non usati dal bundle). Non è possibile eseguire il build in questo ambiente.

3.2 Entry point browser e configurazione applicativa

`main.ts` chiama `enableProdMode()` solo se `environment.production` e poi `bootstrapApplication(AppComponent, appConfig)`, con un `.catch` che fa `console.error` ("It's just an example application file") (projects/storefrontapp/src/main.ts:L13-L23). L'avvio vero e proprio, con l'ordine degli initializer, è descritto nel capitolo 10.

`appConfig` registra (projects/storefrontapp/src/app/app.config.ts:L26-L35):

- `provideHttpClient(withFetch(), withInterceptorsFromDi())`: `withInterceptorsFromDi()` è ciò che rende attivi gli interceptor Spartacus registrati come `HTTP_INTERCEPTORS` nei NgModule (projects/storefrontapp/src/app/app.config.ts:L28-L28);
- `provideClientHydration(withEventReplay(), withNoHttpTransferCache())`: la cache HTTP di trasferimento di Angular è disattivata (angular:packages/platform-browser/src/hydration.ts:L72-L72), perché Spartacus trasferisce lo stato con il proprio meccanismo (vedi 07 — SSR, hydration e TransferState);
- `provideZoneChangeDetection({ eventCoalescing: true })`, `provideBrowserGlobalErrorListeners()`;
- `importProvidersFrom(AppModule)`: tutto Spartacus entra da qui.

`AppComponent` (selettore `app-root`) è standalone e ha come template `<cx-storefront />` (projects/storefrontapp/src/app/app.component.ts:L10-L19). `index.html` contiene `<app-root>Loading...</app-root>`, `<base href="/" />` e due meta tag con placeholder, `OCC_BACKEND_BASE_URL_VALUE` e `MEDIA_BACKEND_BASE_URL_VALUE` (projects/storefrontapp/src/index.html:L71-L82). Le factory che leggono quei meta tag ignorano il valore quando coincide con il placeholder e sono registrate da `MetaTagConfigModule.forRoot()` dentro `BaseCoreModule` (core-libs/core/src/occ/config/config-from-meta-tag-factory.ts:L18-L41, core-libs/core/src/base-core.module.ts:L39-L39): nella demo i placeholder re-

stano, quindi i meta tag non contribuiscono configurazione. Lo stesso file dichiara manifest, favicon, icona apple-touch e splash screen iOS (projects/storefrontapp/src/index.html:L4-L69).

3.3 La composizione dei moduli e l'ordine dei provider

`AppModule` importa, in quest'ordine, `BrowserModule`, `StoreModule.forRoot({})`, `AppRoutingModule`, `EffectsModule.forRoot([])`, `SpartacusModule`, e mette `privateProviders` nei propri `providers` (projects/storefrontapp/src/app/app.module.ts:L15-L25). `SpartacusModule` importa `BaseStorefrontModule`, `SpartacusFeaturesModule`, `SpartacusConfigurationModule` e ri-esporta `BaseStorefrontModule` (projects/storefrontapp/src/app/spartacus/spartacus.module.ts:L12-L20).

Il punto chiave è **l'ordine**: Angular, quando appiattisce un NgModule in lista di provider, include prima i moduli importati semplici (ricorsivamente), poi i provider degli import `ModuleWithProviders` (`forRoot()`), che vengono elaborati dopo tutti gli altri import, e infine i `providers` dichiarati nel modulo stesso (angular:packages/core/src/di/provider_collection.ts:L293-L354, angular:packages/core/src/di/provider_collection.ts:L316-L321). In `AppModule`, quindi, i provider di `StoreModule.forRoot({})` ed `EffectsModule.forRoot([])` entrano dopo l'intero albero di `SpartacusModule`; lo stesso spostamento vale dentro `SpartacusFeaturesModule` per `AuthModule.forRoot()`, `AnonymousConsentsModule.forRoot()`, `ProductModule.forRoot()` ed `ExternalRoutesModule.forRoot()`. Di conseguenza:

1. i chunk di config di `BaseStorefrontModule` e delle librerie entrano per primi;
2. poi quelli di `SpartacusFeaturesModule` (eager + `*FeatureModule`);
3. poi `SpartacusConfigurationModule` (layout, media, CMS, PWA, i18n, canale);
4. **per ultimi** i `privateProviders` di `AppModule`, cioè la config backend e `TestConfigModule`.

Questo è ciò che rende vero il commento "Should be imported after other config modules" accanto a `TestConfigModule.forRoot` (projects/storefrontapp/src/app/private/private.providers.ts:L54-L54). Il merge dei chunk segue quest'ordine: `Config = deepMerge({}, DefaultConfig, RootConfig)` e `RootConfig = deepMerge({}, ...ConfigChunk)` (core-libs/core/src/config/config-tokens.ts:L10-L12, core-libs/core/src/config/config-tokens.ts:L37-L39). Tutti i `provideConfig` dell'app vincono sui default delle librerie e, tra loro, vince l'ultimo. `deepMerge` fonde ricorsivamente solo oggetti; array e primitivi, compreso `undefined`, **sostituiscono** il valore precedente (core-libs/core/src/config/utils/deep-merge.ts:L7-L9, core-libs/core/src/config/utils/deep-merge.ts:L36-L48). Il dettaglio del meccanismo è nel capitolo 11.

`provideConfig` produce un `ValueProvider` multi su `ConfigChunk` (o `DefaultConfigChunk` se `defaultConfig = true`) e `provideConfigFactory` l'equivalente `FactoryProvider` (core-libs/core/src/config/config-providers.ts:L18-L48). La demo usa sempre le varianti **non default**: per questo il suo ESLint spegne le regole `use-provide-default-config(-factory)` e `use-provide-default-feature-toggles(-factory)` che altrove le impongono (projects/storefrontapp/eslint.config.mjs:L10-L15).

3.4 Le tre "fette" di SpartacusModule

SpartacusConfigurationModule. A livello di modulo ES chiama `registerLocaleData` per `de`, `ja`, `zh` (projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L29-L31). I suoi provider, nell'ordine, sono `provideConfigFactory(layoutConfigFactory)`, `provideConfig(mediaConfig)`, `...defaultCmsContentProviders`, `pwa: { enabled: false, addToHomeScreen: true }`, l'i18n statico (risorse en/ja/de/zh, `translationChunksConfig`, `fallbackLang: 'en'`) e infine i provider di canale (projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L44-L72).

- **B2C**: `context.urlParameters: ['baseSite','language','currency']` e `baseSite` con 8 siti electronics/apparel, con `electronics-epdvisualization-spa` anteposto se `environment.epdVisualization` (projects/storefrontapp/src/app/spartacus/spartacus-b2c-configuration.providers.ts:L11-L31); abi-

lita anche `cart.validation.enabled` e `cart.selectiveCart.enabled` (projects/storefrontapp/src/app/spartacus/spartacus-b2c-configuration.providers.ts:L32-L39).

- **B2B**: `provideConfig(defaultB2bOccConfig)`, `provideConfig(defaultB2BCheckoutConfig)` e `context.baseSite = ['powertools-spa','powertools-standalone']`, con `powertools-epdvisualization-spa` aggiunto con `unshift` se EPD (projects/storefrontapp/src/app/spartacus/spartacus-b2b-configuration.providers.ts:L13-L28). `defaultB2bOccConfig`, unica "recipe" di `@spartacus/setup`, contribuisce solo `backend.occ.endpoints` B2B (core-libs/setup/recipes/b2b/config/default-b2b-occ-config.ts:L38-L49).

Il site context che consuma `context.*` è descritto in 13 — Site context e theme; l'i18n in 37 — i18n; la PWA in 40 — SEO e PWA.

SpartacusFeaturesModule. Importa eager auth (`AuthModule.forRoot()`, `LogoutModule`, `LoginRouteModule`), 16 moduli CMS di base, User/AnonymousConsents/Product core+UI, `CostCenterOccModule` e i moduli di page event (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L176-L242). Una sezione "Opt-in features" aggiunge `ExternalRoutesModule.forRoot()` e `JsonLdBuilderModule` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L244-L247). La sezione "Feature libraries" elenca 24 `*FeatureModule` sempre presenti più `...featureModules` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L249-L285). Nei provider:

- `USE_MY_ACCOUNT_V2_CONSENT` e `USE_MY_ACCOUNT_V2_NOTIFICATION_PREFERENCE` valgono `environment.myAccountV2`, "because consents feature is not code-splitted ... and not lazy-loaded" (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L287-L296);
- `provideFeatureTogglesFactory` restituisce un oggetto tipizzato `Required<FeatureToggles>` con 107 chiavi, tutte `true` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L297-L408).

BaseStorefrontModule è la base delle librerie (layout, CMS, routing, ecc.) e viene trattato nei capitoli della Parte II dedicati a quei sottosistemi.

3.5 Il pattern feature module + wrapper

Ogni libreria opzionale entra con un `*FeatureModule` sotto `features/`. Il pattern canonico (es. ASM) è (projects/storefrontapp/src/app/spartacus/features/asm/asm-feature.module.ts:L18-L41):

1. importare **eager** il `*RootModule` della libreria;
2. fornire `provideConfig({ featureModules: { [KEY]: { module: () => import(...) } } });`
3. fornire un `provideConfig` i18n con risorse en/ja/de/zh, `chunks` e spesso `fallbackLang: 'en'`.

La lista dei componenti CMS gestiti da una feature **non** sta nella demo: è il `*RootModule` di libreria a fornirla come default. Per esempio `CartBaseRootModule` mappa 6 componenti su `CART_BASE_FEATURE`, `MiniCartComponent` su `MINI_CART_FEATURE`, `ProductAddToCartComponent` su `ADD_TO_CART_FEATURE` e dichiara l'alias `CART_BASE_CORE_FEATURE → CART_BASE_FEATURE` (feature-libs/cart/base/root/cart-base-root.module.ts:L26-L57, feature-libs/cart/base/root/cart-base-root.module.ts:L77-L83). Il `deepMerge` per chiave unisce `cmsComponents` (default di libreria) e `module` (root config dell'app). `CmsFeaturesService` mappa un componente sulla sua feature **solo** se la feature ha sia `module` sia `cmsComponents` non vuoto (core-libs/storefront/cms-structure/services/cms-features.service.ts:L56-L76). `FeatureModulesService.resolveFeature` risolve gli alias stringa, rifiuta le feature senza `module` ("No module defined for Feature Module ..."), risolve le `dependencies` e carica il modulo una sola volta con `shareReplay` (core-libs/core/src/lazy-loading/feature-modules.service.ts:L42-L73). `FeatureModuleConfig` ha tre campi: `module`, `dependencies`, `cmsComponents` (core-libs/core/src/cms/config/cms-config.ts:L109-L129). Il resto del meccanismo è nel capitolo 12.

Quando una libreria ha **estensioni** da altre librerie, la demo non punta `module` direttamente alla libreria ma a un **wrapper module locale**, che importa il modulo della libreria più le estensioni abilitate dai flag. Esempi:

WRAPPER	BASE	ESTENSIONI CONDIZIONALI	RIFERIMENTO
CartBaseWrapperModule	CartBaseModule	EstimatedDeliveryDateModule (estimatedDeliveryDate), CpqQuoteModule (cpq)	projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L14-L25
CheckoutWrapperModule	CheckoutModule	CheckoutB2BModule + CheckoutScheduledReplenishmentModule (b2b), DigitalPaymentsModule (digitalPayments), S4ServiceCheckoutModule (s4Service)	projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts:L16-L33
OrderWrapperModule	OrderModule	S4ServiceOrderModule, OmfOrderModule, OpfOrderModule	projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts:L14-L27
UserAccountWrapperModule, UserProfileWrapperModule, AdministrationWrapperModule, OrganizationUserRegistrationWrapperModule	modulo lib	modulo CDC corrispondente (cdc)	projects/storefrontapp/src/app/spartacus/features/user/user-account-wrapper.module.ts:L13-L22 e analoghi
CustomerTicketingWrapperModule	modulo lib	CdpCustomerTicketingModule (cdp)	projects/storefrontapp/src/app/spartacus/features/customer-ticketing/customer-ticketing-wrapper.module.ts:L13-L22
RulebasedConfiguratorWrapperModule	modulo lib	RulebasedCpqConfiguratorModule (cpq)	projects/storefrontapp/src/app/spartacus/features/product-configurator/rulebased-configurator-wrapper.module.ts:L12-L21

I wrapper sono 9 e sono raggiunti solo con `import()` dinamico da `featureModules` (projects/storefrontapp/src/app/spartacus/features/cart/cart-base-feature.module.ts:L29-L32, projects/storefrontapp/src/app/spartacus/features/checkout/checkout-feature.module.ts:L81-L84). Il flag `cdp` viene usato **solo** nel wrapper del customer ticketing: non esiste alcun feature module CDP dedicato (projects/storefrontapp/src/app/spartacus/features/customer-ticketing/customer-ticketing-wrapper.module.ts:L13-L22).

Varianti degne di nota:

- `CartBaseFeatureModule` registra tre feature in tre `provideConfig` separati: `CART_BASE_FEATURE` verso il wrapper, `MINI_CART_FEATURE` e `ADD_TO_CART_FEATURE` verso entry point secondari di `@spartacus/cart/base/components` (projects/storefrontapp/src/app/spartacus/features/cart/cart-base-feature.module.ts:L23-L55).
- `CheckoutFeatureModule` importa eager anche `CheckoutB2BRootModule` e `CheckoutScheduledReplenishmentRootModule` se `b2b` e imposta `checkout.guest: true` (projects/storefrontapp/src/app/spartacus/features/checkout/checkout-feature.module.ts:L38-L107).
- `WishListV2FeatureModule` importa `WishListFeatureModule` (V1) e ri-registra solo `CART_WISH_LIST_FEATURE` con `WishListWithV2Module`. Poiché i suoi provider vengono dopo quelli del modulo importato, l'override su `module` vince, mentre `ADD_TO_WISHLIST_FEATURE` e le traduzioni di V1 restano (projects/storefrontapp/src/app/spartacus/features/cart/wish-list-v2-feature.module.ts:L12-L27, projects/storefrontapp/src/app/spartacus/features/cart/wish-list-feature.module.ts:L32-L63).
- `CdsFeatureModule` **non** è lazy: importa `CdsModule.forRoot()` e fornisce `provideConfigFactory(cdsConfigFactory, [WindowRef])` (projects/storefrontapp/src/app/spartacus/features/cds/cds-feature.module.ts:L84-L102). `cdsConfigFactory` restituisce `cds1` sul server; nel browser sceglie la prima config il cui `baseSite` compare in `windowRef.location.href`, con fallback `cds1` (projects/storefrontapp/src/app/spartacus/features/cds/cds-feature.module.ts:L30-L82).
- `OpfFeatureModule` importa 9 root module OPF e registra 9 feature lazy in un solo `provideConfig` (projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L92-L152); la config di checkout dipende dal canale (projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L73-L91).
- `PersonalizationFeatureModule` importa eager `BaseTmsModule.forRoot()`, `GtmModule`, `AepModule` e configura gli eventi inoltrati ai tag manager (projects/storefrontapp/src/app/spartacus/features/tracking/personalization-feature.module.ts:L22-L52).
- Alcuni feature module sono "solo root": `OmfFeatureModule`, `OppsFeatureModule`, `SegmentRefsFeatureModule`, `ProductMultiDimensionalListFeatureModule`; altri importano il root module e aggiungono solo le traduzioni, senza `featureModules` (`CpqQuoteFeatureModule`, `EstimatedDeliveryDateFeatureModule`, `S4OMFeatureModule`) (projects/storefrontapp/src/app/spartacus/features/omf/omf-feature.module.ts:L10-L13, projects/storefrontapp/src/app/spartacus/features/cpq-quote/cpq-quote-feature.module.ts:L18-L35). `OmfRootModule` è addirittura un NgModule vuoto: il codice OMF utile arriva solo con `OmfOrderModule` nel wrapper degli ordini (integration-libs/omf/root/omf-root.module.ts:L9-L10).
- `DigitalPaymentsFeatureModule` non importa alcun root module e fornisce solo traduzioni; `DigitalPaymentsModule` entra soltanto nel wrapper lazy del checkout (projects/storefrontapp/src/app/spartacus/features/digital-payments/digital-payments-feature.module.ts:L17-L33, projects/storefrontapp/src/app/spartacus/features/checkout/checkout-wrapper.module.ts:L22-L24).

3.6 privateProviders e config e2e guidata da cookie

`privateProviders` è un `makeEnvironmentProviders([...])` (projects/storefrontapp/src/app/private/private.providers.ts:L14-L19) che:

- imposta `backend.occ.baseUrl/prefix` da `environment.occBaseUrl/occApiPrefix` e `backend.media.baseUrl/prefix` da `environment.mediaBaseUrl/mediaApiPrefix` (projects/storefrontapp/src/app/private/private.providers.ts:L20-L31). Nessuno dei due file environment valorizza i campi media, e non esiste una variabile `CX_*` per essi (projects/storefrontapp/src/environments/environment.ts:L22-L44, projects/storefrontapp/src/environments/models/build.process.env.d.ts:L13-L33);
- ridefinisce la rotta `product` con due path e `paramsMapping: { name: 'slug' }` "for e2e testing" (projects/storefrontapp/src/app/private/private.providers.ts:L33-L41);
- imposta `features: { level: '*' }`, ma `features.level` è `@deprecated` (projects/storefrontapp/src/app/private/private.providers.ts:L43-L44, core-libs/core/src/features-config/config/features-config.ts:L48-L70);
- imposta `googleMaps.apiKey` a `GOOGLE_MAPS_DEVELOPMENT_KEY_CONFIG`, cioè `'cx-development'` (projects/storefrontapp/src/app/private/private.providers.ts:L46-L49, feature-libs/storefinder/root/config/constants.ts:L7-L7);
- importa `TestOutletModule`, `TestConfigModule.forRoot({ cookie: 'cxConfigE2E' })` e, solo se `!environment.production`, `StoreDevtoolsModule.instrument()` (projects/storefrontapp/src/app/private/private.providers.ts:L52-L56).

`TestConfigModule.forRoot` contribuisce il contenuto di `TEST_CONFIG` due volte: come `FeatureTogglesChunk` (campo `features`) e come `ConfigChunk`, con eslint-disable espliciti ("deliberately providing a high priority FeatureConfig") (core-libs/core/src/config/test-config.module.ts:L83-L106). Nel browser `TEST_CONFIG` legge da `document.cookie` il cookie nominato da `TEST_CONFIG_COOKIE_NAME` e fa `JSON.parse(decodeURIComponent(...))`, restituendo `{}` in caso di errore (core-libs/core/src/config/test-config.module.ts:L42-L63). Sul server lo stesso token viene ridefinito da `TestConfigServerModule.forRoot()`, che legge l'header `Cookie` dalla `REQUEST` express (core-libs/setup/ssr/testing/test-config-server.module.ts:L26-L58). Il JSDoc ricorda il limite di 4096 byte dei cookie (core-libs/core/src/config/test-config.module.ts:L76-L82).

I `FeatureTogglesChunk` sono fusi con `Object.assign` superficiale, quindi vince l'ultimo: prima i 107 toggle dell'app, poi quelli dal cookie (core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L15-L24, core-libs/core/src/features-config/feature-toggles/feature-toggles-tokens.ts:L48-L58).

3.7 Entry point server

`app.config.server.ts` esporta `config = mergeApplicationConfig(appConfig, serverConfig)`, dove `serverConfig` aggiunge `provideServerRendering()`, `importProvidersFrom(AppServerModule)` e `TestConfigServerModule.forRoot()` ("DO NOT USE IN CUSTOMERS APPS") (projects/storefrontapp/src/app/app.config.server.ts:L17-L30). `mergeApplicationConfig` concatena i `providers` nell'ordine degli argomenti: i provider server vengono dopo quelli browser e vincono negli override "last wins" (angular:packages/core/src/application/application_config.ts:L31-L38).

`AppServerModule` fornisce `...provideServer({ serverRequestOrigin: process.env['SERVER_REQUEST_ORIGIN'] })` (projects/storefrontapp/src/app/app.module.server.ts:L10-L17). `provideServer` registra `SERVER_REQUEST_ORIGIN`, `SERVER_REQUEST_URL`, un `LoggerService` server e un `MULTI_ERROR_HANDLER` (core-libs/setup/ssr/providers/ssr-providers.ts:L27-L47). La factory dell'origin dà precedenza all'opzione esplicita, poi al valore dell'express engine, altrimenti lancia un errore che suggerisce `SERVER_REQUEST_ORIGIN=... yarn prerender` (core-libs/setup/ssr/providers/server-request-origin.ts:L14-L40). Il JSDoc spiega che in SSR l'origin è risolta automaticamente da express, mentre per il prerendering è *mandatory* (core-libs/setup/ssr/providers/model.ts:L10-L22).

`main.server.ts` esporta di default `bootstrap(context: BootstrapContext)`, che inoltra il `context` a `bootstrapApplication(AppComponent, config, context)` (projects/storefrontapp/src/main.server.ts:L19-L26).

3.8 server.ts: Express e engine decorato

A livello di modulo, `server.ts` costruisce `ssrOptions` con `timeout = Number(process.env['SSR_TIMEOUT'] ?? defaultSsrOptimizationOptions.timeout)` e `cache = process.env['SSR_CACHE'] === 'true'` (projects/storefrontapp/src/server.ts:L22-L27). Poi crea l'engine decorato, cioè una factory: `NgExpressEngineDecorator.get(engine, ssrOptions)`, dove `engine` è `ngExpressEngine` di `@spartacus/setup/ssr` (projects/storefrontapp/src/server.ts:L8-L15, projects/storefrontapp/src/server.ts:L29-L29). L'istanza di `CxCommonEngine`/`OptimizedSsrEngine` nasce a ogni chiamata di `app()`, quando la factory viene invocata con `{ bootstrap }` in `server.engine('html', ...)`; nella demo `app()` è chiamata una sola volta da `run()` (core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L57-L73, projects/storefrontapp/src/server.ts:L51-L56).

- I default sono `timeout: 3_000`, `cache: false`, `concurrency: 10`, `forcedSsrTimeout: 60_000`, `maxRenderTime: 300_000`, `reuseCurrentRendering: true` e altri (core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L220-L237). Il costruttore di `OptimizedSsrEngine` li fonde con le opzioni parziali (core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L59-L74), quindi passare solo `timeout` e `cache` è sufficiente.
- `decorateExpressEngine` antepone `getServerRequestProviders()` ai provider dell'utente e, se ci sono opzioni di ottimizzazione, avvolge l'istanza in `OptimizedSsrEngine` (core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L51-L74).
- `ngExpressEngine` crea un `CxCommonEngine` (sottoclasse di `CommonEngine`) con `bootstrap`, `providers`, `enablePerformanceProfiler`, `allowedHosts` e calcola l'URL da protocollo, host, `baseUrl` e `url` (core-libs/setup/ssr/engine/ng-express-engine.ts:L82-L106, core-libs/setup/ssr/engine/cx-common-engine.ts:L20-L22).

La funzione `app()`, "exported so that it can be used by serverless Functions" (projects/storefrontapp/src/server.ts:L31-L32):

1. risolve `browserDistFolder = ../browser` da `import.meta.url` e legge **sincronamente** `index.server.html` (projects/storefrontapp/src/server.ts:L32-L37);
2. imposta `trust proxy = 'loopback'` (projects/storefrontapp/src/server.ts:L39-L39);
3. installa `getOriginValidationMiddleware({ allowedOrigins: process.env['SSR_ALLOWED_ORIGINS'] })` (projects/storefrontapp/src/server.ts:L45-L49). Il middleware accetta array o CSV; se la lista è vuota è un no-op, altrimenti risponde `400 Bad Request` con `Cache-Control: no-store` alle origin non ammesse (core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L51-L67). Il confronto è case-insensitive e `*` corrisponde a esattamente un'etichetta host (core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L84-L99). L'origin usa `X-Forwarded-Host` solo se `trust proxy fn` considera fidato il remoteAddress (core-libs/setup/ssr/express-utils/express-request-origin.ts:L9-L26);
4. registra l'engine `html` con `ngExpressEngine({ bootstrap })` e imposta `views` su `browserDistFolder` (projects/storefrontapp/src/server.ts:L51-L59);
5. serve come statico ogni path che contiene un punto (`/.*\..*/`), con `maxAge: '1y'` (projects/storefrontapp/src/server.ts:L61-L67);
6. per tutte le altre rotte chiama `res.render(indexHtml, { req, providers: [{ provide: APP_BASE_HREF, useValue: req.baseUrl }] })` (projects/storefrontapp/src/server.ts:L69-L75);
7. chiude con `defaultExpressErrorHandlers(indexHtmlContent)` (projects/storefrontapp/src/server.ts:L77-L77), che, se gli header non sono già partiti, risponde con il documento CSR, `Cache-Control: no-store` e status 404 per `CmsPageNotFoundOutboundHttpError` oppure 500 per il resto (core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32).

`run()` legge `PORT` (default 4000), chiama `listen` ed è invocata incondizionatamente in fondo al file (projects/storefrontapp/src/server.ts:L82-L97).

`server.ts` **non** passa `allowedHosts` all'engine (projects/storefrontapp/src/server.ts:L51-L56): gli script npm impostano `NG_ALLOWED_HOSTS=localhost` (package.json:L152-L155), che `CommonEngine` legge dall'ambiente con precedenza sull'opzione (deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L108-L111). Se l'host non è ammesso e non c'è alcun allowed host configurato, `CommonEngine.render` logga un errore e restituisce il documento non renderizzato ("Falling back to client side rendering") (deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L113-L130).

Cosa succede *dentro* `OptimizedSsrEngine` (code di rendering, timeout, fallback CSR, cache) è nel capitolo 39.

3.9 Target di build, script SSR e tsconfig

Opzioni di `build`: `outputPath: dist/storefrontapp`, `browser: src/main.ts`, `server: src/main.server.ts`, `ssr.entry: src/server.ts`, `prerender: false`, `polyfills: ["zone.js"]`, `aot: true` (projects/storefrontapp/project.json:L14-L24, projects/storefrontapp/project.json:L142-L147). La configurazione `production` attiva `optimization`, `outputHashing: all`, niente source map, `serviceWorker: false` e `tsConfig: tsconfig.app.prod.json` (projects/storefrontapp/project.json:L150-L171). Esistono anche `development`, `noSsr` e `withPrerender` (con `routesFile: prerender.txt`); il default è `production` (projects/storefrontapp/project.json:L172-L188). `prerender.txt` elenca 11 URL esplicite con baseSite, lingua e valuta nel path (projects/storefrontapp/prerender.txt:L1-L11).

I target `build-csr` e `prerender` sono `concat` che rimandano a `build` con `noSsr` o `withPrerender`; `serve` usa **sempre** `noSsr` (projects/storefrontapp/project.json:L190-L229).

In sviluppo `tsconfig.app.json` estende il `tsconfig.json` di root, dove `@spartacus/*` punta ai sorgenti; in produzione `tsconfig.app.prod.json` rimappa 314 path `@spartacus/*` su `dist/*` (projects/storefrontapp/tsconfig.app.json:L1-L5, tsconfig.json:L795-L796, projects/storefrontapp/tsconfig.app.prod.json:L508-L509). `tsconfig.app.json` disattiva `strict` (con un TODO) e `strictTemplates`, e abilita `skipLibCheck` per la dipendenza `@sapui5/ts-types-esm` di EPD (projects/storefrontapp/tsconfig.app.json:L4-L20).

Script SSR (package.json:L150-L155):

- `serve:ssr` → `NG_ALLOWED_HOSTS=localhost node dist/storefrontapp/server/server.mjs`;
- `serve:ssr:watch`/`serve:ssr:dev` → `SSR_TIMEOUT=30000` e `NODE_TLS_REJECT_UNAUTHORIZED=0`; `serve:ssr:ci` → `SSR_TIMEOUT=0`;
- `dev:ssr` → cancella `dist/storefrontapp/server` e lancia in parallelo `watch` e `serve:ssr:watch`.

3.10 Stili e test outlet

`styles.scss` importa, nell'ordine, `styles-config`, il core Spartacus, i parziali Bootstrap, `@spartacus/styles` e infine `cms-themes`, che deve venire dopo per sovrascrivere le custom property di `:root` (projects/storefrontapp/src/styles.scss:L1-L29). `styles-config.scss` imposta `$useLatestStyles: true` (projects/storefrontapp/src/styles-config.scss:L1-L2), sovrascrivendo il default `false !default` (core-libs/styles/scss/_versioning.scss:L46-L46). `cms-themes.scss` definisce le classi `.santorini`, `.lambda`, `.sparta` che ridefiniscono 24 custom property `--cx-color-*` (projects/storefrontapp/src/cms-themes.scss:L1-L80). Gli stili delle librerie sono 23 entry con `bundleName` distinto (`styles` + 22 `lib-*`) (projects/storefrontapp/project.json:L43-L141). Il resto è nel capitolo 38.

`TestOutletModule` importa tre moduli di pagina di test e `ConfigModule.withConfigFactory(testOutletPagesCmsContentConfig)` (projects/storefrontapp/src/test-outlets/test-

outlet.module.ts:L14-L22). La config definisce in `cmsStructure` tre pagine statiche con `ignoreBackend: true` (projects/storefrontapp/src/test-outlets/test-outlet-cms-page.config.ts:L33-L76); ogni modulo registra una rotta `test/outlet/*` con `canActivate: [CmsPageGuard]` (projects/storefrontapp/src/test-outlets/test-outlet-component/test-outlet-component.module.ts:L17-L32). I template dichiarano `ng-template [cxOutletRef]` in posizione `before`, `after` e replace (projects/storefrontapp/src/test-outlets/test-outlet-component/test-outlet-component.component.html:L1-L13). Sono un buon esempio minimo d'uso degli outlet (vedi 17 — Outlet).

---

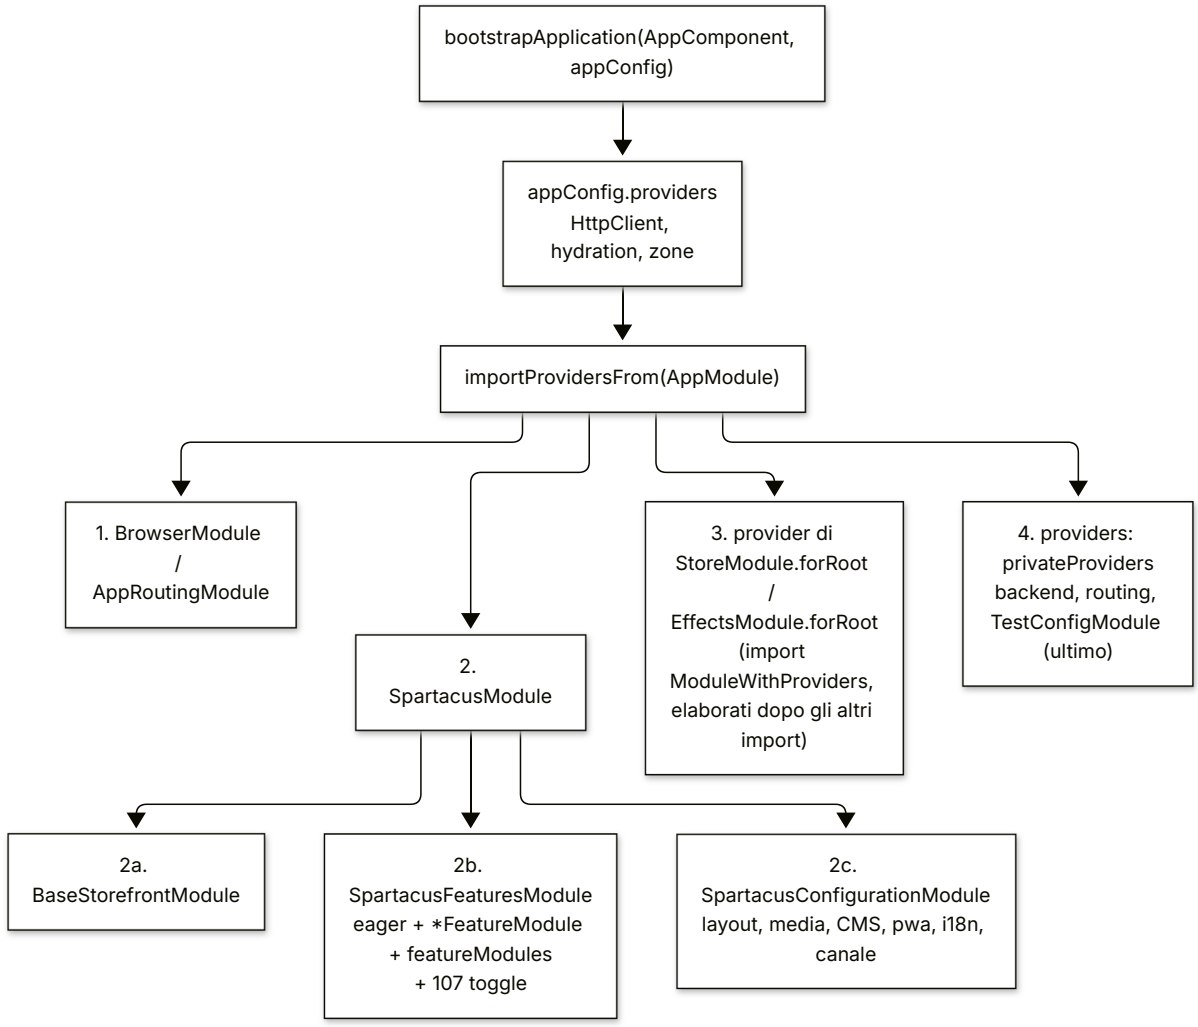
4. Diagrammi

4.1 Dai flag di build alla struttura dell'app

■ **TAVOLA 47.1** diagramma a tutta pagina, in fondo al capitolo

Riferimenti: package.json:L16-L16, .env-cmdrc:L2-L4, projects/storefrontapp/project.json:L9-L13, projects/storefrontapp/esbuild/plugins.ts:L10-L31, projects/storefrontapp/project.json:L157-L162, projects/storefrontapp/src/environments/environment.ts:L22-L44, projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L115-L175, projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L40-L42, projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L14-L25, projects/storefrontapp/src/app/private/private.providers.ts:L20-L31.

4.2 Albero dei moduli e ordine dei provider



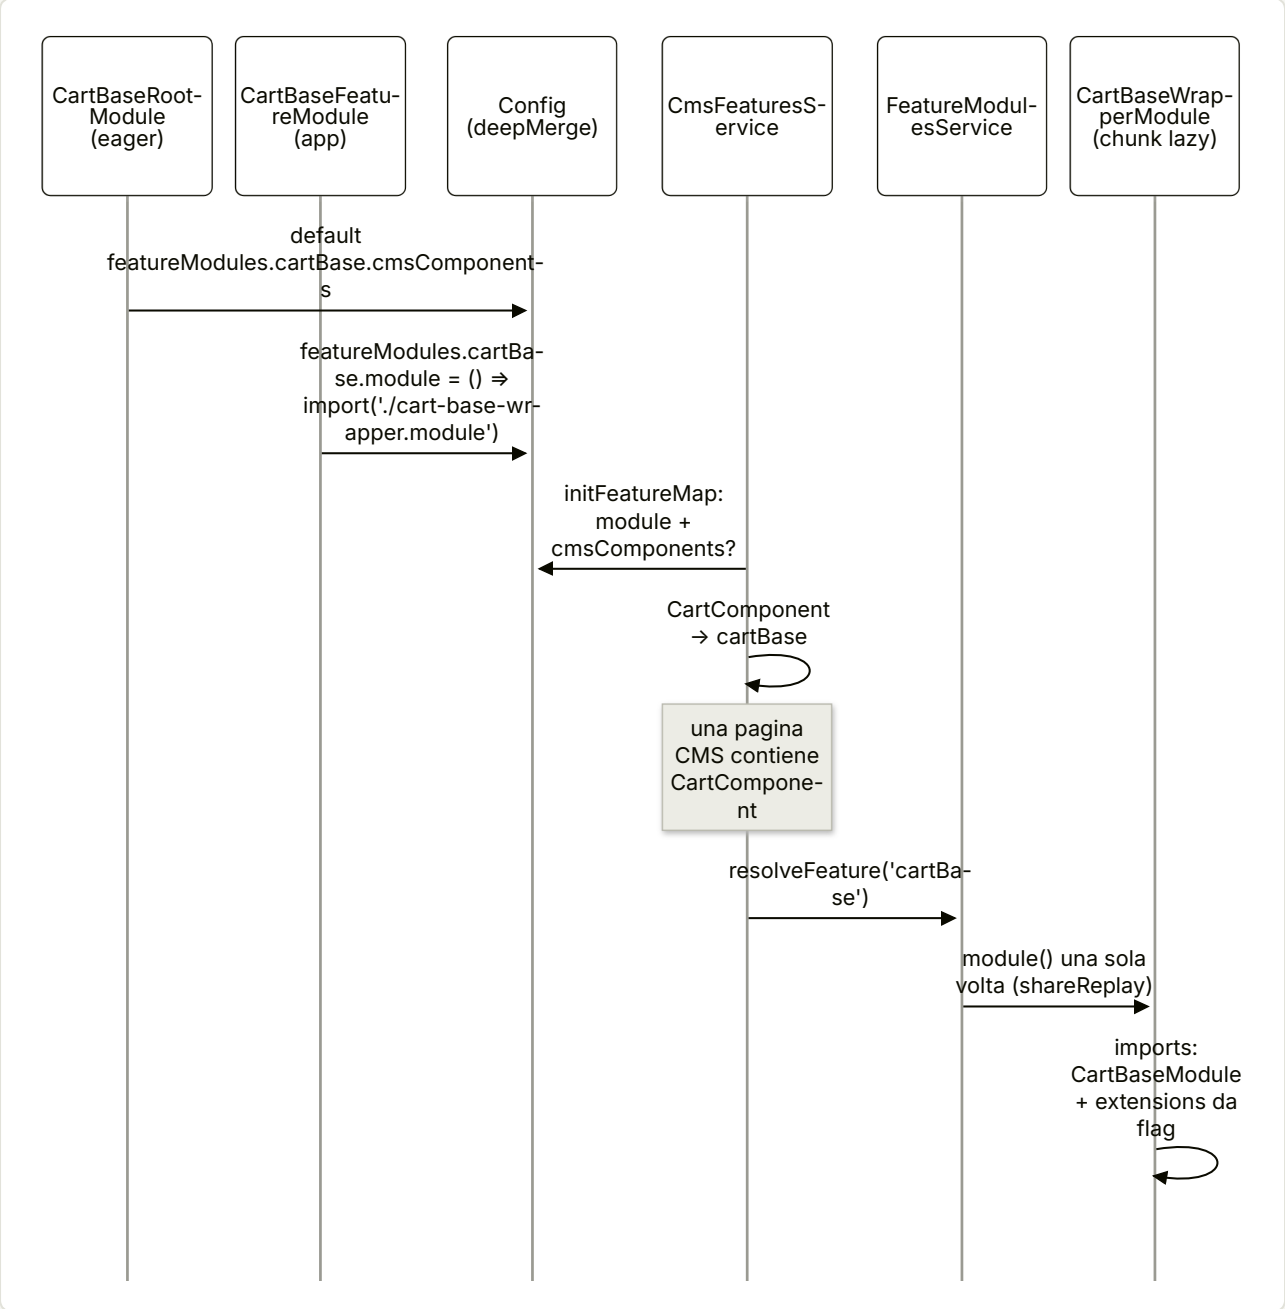
L'ordine numerico è l'ordine in cui i provider entrano nella lista (prima gli `imports` semplici, poi i provider degli import `forRoot()`, poi i `providers`): projects/storefrontapp/src/app/app.module.ts:L15-L25, projects/storefrontapp/src/app/spartacus/spartacus.module.ts:L12-L20, angular:packages/core/src/di/provider_collection.ts:L293-L354, angular:packages/core/src/di/provider_collection.ts:L316-L321.

4.3 Richiesta SSR

■ **TAVOLA 47.2** diagramma a tutta pagina, in fondo al capitolo

Riferimenti: projects/storefrontapp/src/server.ts:L45-L77, core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L51-L67, core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L51-L74, deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L108-L130, projects/storefrontapp/src/main.server.ts:L23-L24, core-libs/setup/ssr/error-handling/express-error-handlers/express-error-handlers.ts:L21-L32.

4.4 Lazy loading di una feature con wrapper (cart)



Riferimenti: `feature-libs/cart/base/root/cart-base-root.module.ts:L26-L57`, `projects/storefrontapp/src/app/spartacus/features/cart/cart-base-feature.module.ts:L23-L35`, `core-libs/storefront/cms-structure/services/cms-features.service.ts:L56-L76`, `core-libs/core/src/lazy-loading/feature-modules.service.ts:L42-L73`, `projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L14-L25`.

5. Estratti di codice reale

5.1 Il plugin che porta i flag nel bundle

projects/storefrontapp/esbuild/plugins.ts:L10-L31

```ts
const resolveEnvPlugin: Plugin = {
  name: 'resolve-env-plugin',
  setup(build) {
    const env: Record<string, string | boolean | undefined> = {};
    Object.keys(process.env).forEach((key) => {
      if (key.startsWith('CX_')) {
        if (process.env[key] === 'true') {
          env[key] = true;
        } else if (process.env[key] === 'false') {
          env[key] = false;
        } else {
          env[key] = process.env[key];
        }
      }
    });
    build.initialOptions.define = {
      ...build.initialOptions.define,
      'buildProcess.env': JSON.stringify(env),
    };
    console.log('env=', env); // eslint-disable-line no-console
  },
};
```

5.2 L'oggetto environment di sviluppo

projects/storefrontapp/src/environments/environment.ts:L22-L30

```ts
export const environment: Environment = {
  production: false,
  occBaseUrl: buildProcess.env.CX_BASE_URL,
  occApiPrefix: '/occ/v2/',
  cds: buildProcess.env.CX_CDS ?? false,
  b2b: buildProcess.env.CX_B2B ?? false,
  cdc: buildProcess.env.CX_CDC ?? false,
  cdp: buildProcess.env.CX_CDP ?? false,
  cpq: buildProcess.env.CX_CPQ ?? false,
  // ...
};
```

5.3 La configurazione applicativa browser e server

projects/storefrontapp/src/app/app.config.ts:L26-L35

```ts
export const appConfig: ApplicationConfig = {
  providers: [
    provideHttpClient(withFetch(), withInterceptorsFromDi()),
    provideClientHydration(withEventReplay(), withNoHttpTransferCache()),
    provideZoneChangeDetection({ eventCoalescing: true }),
    provideBrowserGlobalErrorListeners(),

    importProvidersFrom(AppModule),
  ],
};
```

projects/storefrontapp/src/app/app.config.server.ts:L17-L30

```ts
const serverConfig: ApplicationConfig = {
  providers: [
    provideServerRendering(),

    importProvidersFrom(AppServerModule),

    importProvidersFrom(
      // DO NOT USE IN CUSTOMERS APPS:
      TestConfigServerModule.forRoot() // Injects config dynamically from e2e tests for SSR.
    ),
  ],
};

export const config = mergeApplicationConfig(appConfig, serverConfig);
```

projects/storefrontapp/src/main.server.ts:L23-L26

```ts
const bootstrap = (context: BootstrapContext) =>
  bootstrapApplication(AppComponent, config, context);

export default bootstrap;
```

5.4 AppModule: imports prima, privateProviders dopo

projects/storefrontapp/src/app/app.module.ts:L15-L25

```ts
@NgModule({
  imports: [
    BrowserModule,
    StoreModule.forRoot({}),
    AppRoutingModule,
```

```
    EffectsModule.forRoot([]),
    SpartacusModule,
  ],
  providers: [privateProviders],
})
export class AppModule {}
```

projects/storefrontapp/src/app/private/private.providers.ts:L52-L56

```ts
  importProvidersFrom(
    TestOutletModule, // Custom usages of cxOutletRef only for e2e testing
    TestConfigModule.forRoot({ cookie: 'cxConfigE2E' }), // Injects config dynamically from e2e tests. Should be imported after other config modules.
    ...(environment.production ? [] : [StoreDevtoolsModule.instrument()]) // Enable Redux devtools only in non-production build
  ),
```

5.5 Feature module scelti a import-time

projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L115-L133

```ts
const featureModules = [];

if (environment.b2b) {
  featureModules.push(
    AdministrationFeatureModule,
    AccountSummaryFeatureModule,
    BulkPricingFeatureModule,
    OrderApprovalFeatureModule,
    OrganizationUserRegistrationFeatureModule,
    UnitOrderFeatureModule,
    FutureStockFeatureModule
  );
} else {
  featureModules.push(PickupInStoreFeatureModule);
}

if (environment.cdc) {
  featureModules.push(CdcFeatureModule);
}
```

projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L297-L300

```ts
    provideFeatureTogglesFactory(() => {
      const appFeatureToggles: Required<FeatureToggles> = {
        useAdvancedGoogleMarkers: true,
        useGoogleMapsAsyncLoading: true,
```

5.6 Scelta del canale

projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L40-L42

```ts
const spartacusChannelSpecificConfigurationProviders = environment.b2b
  ? spartacusB2bConfigurationProviders
  : spartacusB2cConfigurationProviders;
```

5.7 Feature module e wrapper

projects/storefrontapp/src/app/spartacus/features/cart/cart-base-feature.module.ts:L23-L35

```ts
@NgModule({
  imports: [CartBaseRootModule],
  providers: [
    provideConfig({
      featureModules: {
        [CART_BASE_FEATURE]: {
          module: () =>
            import('./cart-base-wrapper.module').then(
              (m) => m.CartBaseWrapperModule
            ),
        },
      },
    }),
```

projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L14-L25

```ts
const extensions: Type<any>[] = [];

if (environment.estimatedDeliveryDate) {
  extensions.push(EstimatedDeliveryDateModule);
}
if (environment.cpq) {
  extensions.push(CpqQuoteModule);
}
@NgModule({
  imports: [CartBaseModule, ...extensions],
})
export class CartBaseWrapperModule {}
```

5.8 server.ts

projects/storefrontapp/src/server.ts:L22-L37

```ts
const ssrOptions: SsrOptimizationOptions = {
  timeout: Number(
    process.env['SSR_TIMEOUT'] ?? defaultSsrOptimizationOptions.timeout
```

```
  ),
  cache: process.env['SSR_CACHE'] === 'true',
};

const ngExpressEngine = NgExpressEngineDecorator.get(engine, ssrOptions);

// The Express app is exported so that it can be used by serverless Functions.
export function app(): express.Express {
  const server = express();
  const serverDistFolder = dirname(fileURLToPath(import.meta.url));
  const browserDistFolder = resolve(serverDistFolder, '../browser');
  const indexHtml = join(serverDistFolder, 'index.server.html');
  const indexHtmlContent = readFileSync(indexHtml, 'utf-8');
```

projects/storefrontapp/src/server.ts:L61-L77

```ts
  // Serve static files from /browser
  server.get(
    /.*\..*/,
    express.static(browserDistFolder, {
      maxAge: '1y',
    })
  );

  // All regular routes use the Universal engine
  server.get(/.*/, (req, res) => {
    res.render(indexHtml, {
      req,
      providers: [{ provide: APP_BASE_HREF, useValue: req.baseUrl }],
    });
  });

  server.use(defaultExpressErrorHandlers(indexHtmlContent));
```

5.9 Engine decorato (libreria)

core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L59-L72

```ts
    const engineInstance = ngExpressEngine({
      ...setupOptions,
      providers: [
        // add spartacus related providers
        ...getServerRequestProviders(),
        ...(setupOptions.providers ?? []),
      ],
    });

    // apply optimization wrapper if optimization options were defined
```

```
    return optimizationOptions
      ? new OptimizedSsrEngine(engineInstance, optimizationOptions)
          .engineInstance
      : engineInstance;
```

6. Configurazione

CHIAVE	TIPO	DEFAULT	DEFINITA IN	LETTA IN

7. Commenti e note notevoli dal sorgente

- "It's just an example application file. This message is not crucial to be logged using any special logger." — `projects/storefrontapp/src/main.ts:L18-L22`, ripetuto in `projects/storefrontapp/src/server.ts:L88-L92`.
- "Load `$localize` onto the global scope - used if i18n tags appear in Angular templates." — `projects/storefrontapp/src/main.server.ts:L7-L9`. È un **residuo**: il file non importa `@angular/localize` (`projects/storefrontapp/src/main.server.ts:L7-L17`).
- "// All regular routes use the Universal engine" — `projects/storefrontapp/src/server.ts:L69-L69`: riferimento storico ad Angular Universal; oggi l'engine è `CxCommonEngine` su `@angular/ssr`.
- "Validates the resolved request origin against an allowlist … when unset or empty the middleware is a no-op." — `projects/storefrontapp/src/server.ts:L41-L44`.
- "DO NOT USE IN CUSTOMERS APPS" — `projects/storefrontapp/src/app/app.config.server.ts:L24-L25`; "CAUTION: IT IS NOT MEANT FOR CUSTOMERS' APPLICATIONS!" — `projects/storefrontapp/src/app/private/private.providers.ts:L17-L17`; "CAUTION: DON'T USE IT IN PRODUCTION! IT HASN'T BEEN REVIEWED FOR SECURITY ISSUES." — `core-libs/core/src/config/test-config.module.ts:L81-L81`, `core-libs/setup/ssr/testing/test-config-server.module.ts:L34-L34`.

- "Should be imported after other config modules." — projects/storefrontapp/src/app/private/private.providers.ts:L54-L54: è vero per costruzione, grazie all'ordine imports→providers (§3.3).
- "LogoutModule, // will be come part of auth package" — projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L180-L181.
- "ExternalRoutesModule.forRoot(), // to opt-in explicitly, is added by default schematics" — projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L246-L246.
- "Adding the provider here because consents feature is not code-splitted to separate library and not lazy-loaded" — projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L288-L288.
- "we bring in static translations to be up and running soon right away" — projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts:L56-L56.
- JSDoc di `WishListFeatureModule`: API legacy V1 basata su SavedCart; per nuove installazioni V2 (endpoint `/wishlists`, da SAP Commerce Cloud 2211-jdk21.9) — projects/storefrontapp/src/app/spartacus/features/cart/wish-list-feature.module.ts:L22-L31.
- "Only differences to the default cds config, they are merged together." — projects/storefrontapp/src/app/spartacus/features/cds/cds-feature.module.ts:L23-L28.
- Il commento in testa a `environment.ts` cita `ng build --env=prod` e `angular.json`: è **obsoleto**, oggi la sostituzione avviene con `fileReplacements` in `project.json` — projects/storefrontapp/src/environments/environment.ts:L7-L10, projects/storefrontapp/project.json:L157-L162.
- "This import should be commented out in production mode..." su `zone.js/plugins/zone-error` — projects/storefrontapp/src/environments/environment.ts:L12-L19.
- "TODO: Fix strict errors and remove this option" — projects/storefrontapp/tsconfig.app.json:L5-L5.
- "Angular 21 introduced a change that causes NG0100 errors in Karma tests ... we must manually provide zone change detection." — projects/storefrontapp/src/test.ts:L30-L46.
- "CMS-driven base-site theme rules (must come after Spartacus styles so the CSS custom properties override the defaults in `:root`)." — projects/storefrontapp/src/styles.scss:L27-L29.
- La regola ESLint `no-storefrontapp-false-feature-toggles` spiega che tutti i toggle devono essere `true` "so that developers exercise new code paths daily" — tools/eslint-rules/rules/no-storefrontapp-false-feature-toggles.ts:L33-L45.

---

8. Extension point

La demo è soprattutto un **catalogo di esempi** degli extension point pubblici. Ecco quelli che vale la pena copiare in un'app cliente, e quelli da non copiare.

Da imitare (API pubbliche):

SIMBOLO	USO NELLA DEMO	DEFINIZIONE	RICETTA
`provideConfig`, `provideConfigFactory`	tutti i chunk di config dell'app	core-libs/core/src/config/config-providers.ts:L18-L48	50 — Ricette: configurazione, DI, interceptor, eventi
`provideFeatureTogglesFactory`, `FeatureToggles`	107 toggle	core-libs/core/src/features-config/feature-toggles/feature-toggles-providers.ts:L44-L52	50, 54 — Upgrade-safe
`CmsConfig.featureModules` / `FeatureModuleConfig` + `*RootModule`	ogni `*FeatureModule`	core-libs/core/src/cms/config/cms-config.ts:L109-L129	53 — Feature lib lazy, carrello/checkout, stili, traduzioni

SIMBOLO	USO NELLA DEMO	DEFINIZIONE	RICETTA
Wrapper module lazy (modulo lib + estensioni)	9 wrapper	projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L14-L25	53
`ConfigModule.withConfigFactory` + `cmsStructure` statica	test outlet	core-libs/core/src/config/config.module.ts:L44-L53, projects/storefrontapp/src/test-outlets/test-outlet-cms-page.config.ts:L33-L76	51 — Componenti CMS, outlet, route e layout
`cxOutletRef` before/after/replace	test outlet	projects/storefrontapp/src/test-outlets/test-outlet-component/test-outlet-component.component.html:L1-L13	51
`routing.routes.<page>.paths/paramsMapping`	rotta product	projects/storefrontapp/src/app/private/private.providers.ts:L33-L41	51
`defaultB2bOccConfig` (recipe)	canale B2B	core-libs/setup/recipes/b2b/config/default-b2b-occ-config.ts:L38-L49	52 — OCC, adapter, converter, endpoint
`NgExpressEngineDecorator`, `SsrOptimizationOptions`, `getOriginValidationMiddleware`, `defaultExpressErrorHandlers`, `provideServer`	`server.ts`, `AppServerModule`	core-libs/setup/ssr/engine-decorator/ng-express-engine-decorator.ts:L51-L74, core-libs/setup/ssr/express-utils/express-origin-validation-middleware.ts:L51-L67, core-libs/setup/ssr/providers/ssr-providers.ts:L27-L47	39 — SSR ottimizzato
i18n per feature (`resources`, `chunks`, `fallbackLang`)	ogni feature module	projects/storefrontapp/src/app/spartacus/features/asm/asm-feature.module.ts:L18-L41	53
Override SCSS via ordine degli import + custom property di tema	`styles.scss`, `cms-themes.scss`	projects/storefrontapp/src/styles.scss:L1-L29	53
Meta tag `occ-backend-base-url` / `media-backend-base-url`	presenti ma inerti (placeholder)	core-libs/core/src/occ/config/config-from-meta-tag-factory.ts:L18-L41	52

Da non imitare (solo repo): `TestConfigModule` e `TestConfigServerModule` (config da cookie, mai revisionata per la sicurezza), `features.level: '*'` (deprecato), il plugin esbuild `buildProcess.env` e l'`if` sui flag per scegliere moduli (un'app cliente sceglie le librerie a `ng add`), `Required<FeatureToggles>` con tutti i toggle `true` (in un'app cliente accendere un toggle è una decisione consapevole, vedi 42). La checklist completa è in 54 — API pubblica vs interna, upgrade, anti-pattern.

9. Trappole, casi limite, comportamenti controintuitivi

1. **L'ordine dei moduli è l'ordine degli override.** `TestConfigModule` vince solo perché sta nei `providers` di `AppModule`, processati dopo gli `imports`. Spostarlo in un modulo importato prima di `SpartacusModule` lo renderebbe inefficace (projects/storefrontapp/src/app/app.module.ts:L16-L23, angular:packages/core/src/di/provider_collection.ts:L293-L354). Lo stesso vale per `WishListV2FeatureModule`, che vince su V1 perché ne importa il modulo e poi aggiunge i propri provider (projects/storefrontapp/src/app/spartacus/features/cart/wish-list-v2-feature.module.ts:L12-L27).

2. **Gli array vengono sostituiti, non uniti.** `context.baseSite`, `cdc[]`, `tagManager.*.events` sono array: un `provideConfig` successivo li rimpiazza interamente (core-libs/core/src/config/utils/deep-merge.ts:L7-L9).
3. `backend.media.baseUrl: undefined` **sovrascrive.** `privateProviders` scrive esplicitamente `undefined` per i campi media, e in `deepMerge` un `undefined` sostituisce i valori precedenti, compreso un eventuale meta tag `media-backend-base-url`. Il normalizer delle immagini ripiega su `occ.baseUrl` (projects/storefrontapp/src/app/private/private.providers.ts:L27-L30, core-libs/core/src/config/utils/deep-merge.ts:L36-L48, core-libs/core/src/occ/adapters/product/converters/product-image-normalizer.ts:L95-L99). Lo stesso vale per `occ.baseUrl` rispetto a un meta tag `occ-backend-base-url` reale (core-libs/core/src/base-core.module.ts:L39-L39).
4. `environment.prod.ts` **senza** `?? false`. Con flag non impostati i valori sono `undefined`: falsy, ma non del tipo `boolean` dichiarato (projects/storefrontapp/src/environments/environment.prod.ts:L13-L30).
5. **Solo le variabili** `CX_*` **arrivano al bundle.** `SSR_*`, `PORT`, `SERVER_REQUEST_ORIGIN`, `NG_ALLOWED_HOSTS` sono lette a runtime da Node, non a build (projects/storefrontapp/esbuild/plugins.ts:L15-L15, projects/storefrontapp/src/server.ts:L22-L27).
6. **I flag sono decisi a build time.** Cambiare `CX_B2B` richiede un nuovo build: `featureModules` ed `extensions` sono calcolati a import-time e congelati dal decoratore `@NgModule` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L115-L129, projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L285-L285).
7. **Import statici nei wrapper.** I moduli di estensione (`CpqQuoteModule`, `DigitalPaymentsModule`, ...) sono importati staticamente anche quando il flag è falso (projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L10-L12). DA VERIFICARE se finiscano o meno nel chunk: dipende dal tree-shaking di esbuild, e il build non è eseguibile qui.
8. `Required<FeatureToggles>` **rompe la compilazione** a ogni nuovo toggle in core finché non viene aggiunto alla demo, e la regola lint impone che sia `true` (projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L298-L298, projects/storefrontapp/eslint.config.mjs:L24-L30).
9. **Feature senza** `module` **non vengono mappate ai componenti CMS.** `PRODUCT_MULTI_DIMENSIONAL_LIST_FEATURE` dichiara `cmsComponents` ma l'app non fornisce `module`; resta attivo solo l'outlet `ProductListOutlets.ITEM_DETAILS` in `REPLACE` (feature-libs/product-multi-dimensional/list/root/product-multi-dimensional-list-root.module.ts:L19-L44, core-libs/storefront/cms-structure/services/cms-features.service.ts:L56-L76).
10. **CDS sceglie la config per sottostringa dell'URL.** `location.href.includes(baseSite)` e, sul server, sempre `cds1`: SSR e browser possono divergere (projects/storefrontapp/src/app/spartacus/features/cds/cds-feature.module.ts:L30-L82).
11. **Placeholder non funzionanti** nella config demo: `JS_SDK_URL_PLACEHOLDER` (CDC), `A_CDS_*` (CDS 2), `ADD_COMMERCE_CLOUD_PUBLIC_KEY_HERE` (OPF) (projects/storefrontapp/src/app/spartacus/features/cdc/cdc-feature.module.ts:L20-L33, projects/storefrontapp/src/app/spartacus/features/opf/opf-feature.module.ts:L186-L193).
12. **Statici per qualunque path con un punto** (`/.*\..*/`): anche URL applicative con un punto passano prima da `express.static` (projects/storefrontapp/src/server.ts:L61-L67). DA VERIFICARE il fallthrough di `express.static` verso il catch-all di rendering quando il file non esiste: il pacchetto `express` non è disponibile in `/tmp/deps`.
13. `index.server.html` **è letto con** `readFileSync` **all'avvio.** Se manca (dist incompleto o non coerente, per esempio un `server/` vecchio), `app()` lancia prima di `listen` (projects/storefrontapp/src/server.ts:L36-L37). Con un build `noSsr` (`ssr: false`) non c'è proprio un server da avviare (projects/storefrontapp/project.json:L177-L180).
14. **Nessun** `allowedHosts` **in codice.** Senza `NG_ALLOWED_HOSTS` (e senza `allowedHosts`), `CommonEngine` logga un errore e degrada a CSR. Se invece `NG_ALLOWED_HOSTS` è impostata (come in tutti gli script `serve:ssr*`) e

l'host della richiesta non vi compare, `render` lancia l'errore `URL with hostname "..." is not allowed.`, senza fallback (projects/storefrontapp/src/server.ts:L51-L56, deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L119-L133, deps:angular-ssr-21.2.23/package/fesm2022/_validation-chunk.mjs:L15-L22).

15. `trust proxy = 'loopback'`. Dietro un reverse proxy non loopback `X-Forwarded-Host` viene ignorato e l'origin (usata dall'allowlist e da `SERVER_REQUEST_ORIGIN`) è l'header `Host` (projects/storefrontapp/src/server.ts:L39-L39, core-libs/setup/ssr/express-utils/express-request-origin.ts:L9-L26).
16. **Il prerender richiede** `SERVER_REQUEST_ORIGIN`, altrimenti `serverRequestOriginFactory` lancia (core-libs/setup/ssr/providers/server-request-origin.ts:L14-L40).
17. **Il build production compila contro** `dist/`. `tsconfig.app.prod.json` mappa `@spartacus/*` su `dist/*`, quindi `build`/`build:ssr` (default `production`) richiedono le librerie già buildate, mentre `start` usa i sorgenti (projects/storefrontapp/tsconfig.app.prod.json:L508-L509, projects/storefrontapp/project.json:L172-L188).
18. `serve` **non fa mai SSR.** Entrambe le configurazioni usano `noSsr`; per SSR in sviluppo serve `dev:ssr` (projects/storefrontapp/project.json:L190-L229, package.json:L151-L151).
19. **Stili non bundlati.** `lib-customer-360.scss` e `lib-estimated-delivery-date.scss` esistono ma non sono elencati in `project.json` (projects/storefrontapp/src/styles/lib-customer-360.scss:L1-L2, projects/storefrontapp/project.json:L43-L141). DA VERIFICARE se gli stili ASM 360 ed EDD arrivino per altra via.
20. `lib-customer-ticketing`, `lib-s4om`, `lib-subscription-billing` **non importano** `styles-config`, quindi per quelle librerie `$useLatestStyles` resta al default `false` (projects/storefrontapp/src/styles/lib-customer-ticketing.scss:L1-L1, core-libs/styles/scss/_versioning.scss:L46-L46).
21. `"types": ["node"]` **fuori da** `compilerOptions` in `tsconfig.app.json`, dove TypeScript non lo considera un'opzione di compilazione (projects/storefrontapp/tsconfig.app.json:L3-L11).
22. **Script non uniformi.** `build:ssr:ci` e `test:ssr` non usano `--no-override` (package.json:L54-L57, package.json:L156-L157); `start:opf`/`start:punchout` non includono né `dev` né `b2c` (package.json:L137-L141), e l'ambiente `punchout` non definisce `CX_BASE_URL` (.env-cmdrc:L101-L104).
23. `.env-cmdrc` **contiene IP e host di ambienti interni** (.env-cmdrc:L3-L3). Gli script `serve:ssr:watch`, `serve:ssr:ci`, `serve:ssr:dev` e `prerender` disabilitano la verifica TLS con `NODE_TLS_REJECT_UNAUTHORIZED=0` (DA VERIFICARE il motivo: nessun file del repo lo spiega; presumibilmente i certificati degli ambienti in `.env-cmdrc`, ad es. un host raggiunto per IP). `serve:ssr` non la imposta (package.json:L152-L155, package.json:L158-L158). Non va riprodotto in produzione.

---

10. Come fare debug

- **Quali flag sono finiti nel bundle?** Il plugin stampa `env=` con l'oggetto `CX_*` all'inizio del build (projects/storefrontapp/esbuild/plugins.ts:L29-L29). Se un flag non compare, controllare quali ambienti `env-cmd` sono stati passati e se la shell ha già la variabile (con `--no-override`).
- **Quale config ha vinto?** Iniettare `Config` (o `FeatureToggles`) in un componente o dalla console e confrontare con l'ordine del §3.3. Per un override veloce senza rebuild, sfruttare il cookie `cxConfigE2E` con JSON URI-encoded (core-libs/core/src/config/test-config.module.ts:L42-L63): funziona anche in SSR grazie a `TestConfigServerModule` (core-libs/setup/ssr/testing/test-config-server.module.ts:L26-L58). Attenzione al limite di 4096 byte.
- **NgRx DevTools** sono attivi solo nei build non production (projects/storefrontapp/src/app/private/private.providers.ts:L55-L55).

- **Stack trace leggibili**: in sviluppo `environment.ts` importa `zone.js/plugins/zone-error` (projects/storefrontapp/src/environments/environment.ts:L12-L19).
- **Una feature non si carica?** Verificare che la chiave in `featureModules` abbia sia `cmsComponents` (dal root module) sia `module` (dall'app); altrimenti `CmsFeaturesService` non mappa il componente (core-libs/storefront/cms-structure/services/cms-features.service.ts:L56-L76) e `FeatureModulesService` lancia "No module defined for Feature Module" (core-libs/core/src/lazy-loading/feature-modules.service.ts:L42-L73). Nel pannello Network del browser si vede il chunk lazy richiesto al primo componente.
- **SSR che restituisce sempre CSR?** Guardare la console di Node: senza alcun allowed host configurato (né `NG_ALLOWED_HOSTS` né `allowedHosts`) compare l'errore "Falling back to client side rendering"; se invece `NG_ALLOWED_HOSTS` è impostata ma non contiene l'host richiesto, la richiesta fallisce con `URL with hostname "..." is not allowed.` senza fallback (deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L113-L133). Altrimenti aumentare `SSR_TIMEOUT` (gli script di sviluppo usano 30000, package.json:L153-L155) e consultare i log dell'engine ottimizzato (cap. 39).
- **400 Bad Request su tutte le richieste SSR**: `SSR_ALLOWED_ORIGINS` è impostata e l'origin calcolata non corrisponde; ricordare `trust proxy = 'loopback'` (projects/storefrontapp/src/server.ts:L39-L49).
- **Ciclo di sviluppo SSR**: `npm run dev:ssr` ricompila in watch e riavvia Node quando cambia `dist/storefrontapp/server/` (package.json:L151-L153).
- **Test Karma della demo con NG0100**: vedere il workaround `ZoneChangeDetectionModule` in projects/storefrontapp/src/test.ts:L30-L46.

---

11. Domande di autoverifica

1. **Perché `TestConfigModule` riesce a sovrascrivere qualsiasi config dell'app?** Perché sta nei `providers` di `AppModule` (tramite `privateProviders`), che Angular include dopo i provider di tutti gli `imports`; il `deepMerge` dei `ConfigChunk` fa vincere l'ultimo. — projects/storefrontapp/src/app/app.module.ts:L15-L25, angular:packages/core/src/di/provider_collection.ts:L293-L354, core-libs/core/src/config/config-tokens.ts:L37-L39
2. **Come arriva `CX_B2B=true` dalla shell a `environment.b2b`?** `env-cmd` carica l'ambiente da `.env-cmdrc`; il plugin esbuild `resolve-env-plugin` raccoglie le `CX_*`, converte `'true'` in `true` e le definisce come `buildProcess.env`; `environment.ts` legge `buildProcess.env.CX_B2B ?? false`. — .env-cmdrc:L51-L57, projects/storefrontapp/esbuild/plugins.ts:L10-L31, projects/storefrontapp/src/environments/environment.ts:L27-L27
3. **Si può passare da B2C a B2B impostando una variabile d'ambiente sul server Node già buildato?** No: i flag sono iniettati a build time e usati a import-time per costruire `featureModules` e i provider di canale. Solo `SSR_*`, `PORT`, `SERVER_REQUEST_ORIGIN`, `SSR_ALLOWED_ORIGINS`, `NG_ALLOWED_HOSTS` sono runtime. — projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L115-L129, projects/storefrontapp/src/server.ts:L22-L27
4. **Perché la demo punta `featureModules[CART_BASE_FEATURE].module` a un wrapper locale e non a `@spartacus/cart/base`?** Perché il wrapper importa `CartBaseModule` più le estensioni (EDD, CPQ) abilitate dai flag, nello stesso chunk lazy. — projects/storefrontapp/src/app/spartacus/features/cart/cart-base-feature.module.ts:L23-L35, projects/storefrontapp/src/app/spartacus/features/cart/cart-base-wrapper.module.ts:L14-L25
5. **Dove è definita la lista dei componenti CMS che fanno scattare il caricamento lazy del carrello?** Nel `CartBaseRootModule` della libreria, come default; l'app aggiunge solo `module`, e `CmsFeaturesService` mappa i componenti solo se esistono entrambi. — feature-libs/cart/base/root/cart-base-root.module.ts:L26-L57, core-libs/storefront/cms-structure/services/cms-features.service.ts:L56-L76

6. **Cosa succede se avvio** `serve:ssr` **senza** `NG_ALLOWED_HOSTS`**?** `server.ts` non passa `allowedHosts`, quindi `CommonEngine` non ha host ammessi: logga un errore e restituisce il documento non renderizzato (fallback CSR). — projects/storefrontapp/src/server.ts:L51-L56, deps:angular-ssr-21.2.23/package/fesm2022/node.mjs:L108-L130
7. **Quali opzioni di ottimizzazione SSR configura la demo, e da dove prende le altre?** Solo `timeout` (da `SSR_TIMEOUT`, default 3000) e `cache` (da `SSR_CACHE === 'true'`). Le altre vengono da `defaultSsrOptimizationOptions`, fuse nel costruttore di `OptimizedSsrEngine`. — projects/storefrontapp/src/server.ts:L22-L27, core-libs/setup/ssr/optimized-engine/ssr-optimization-options.ts:L220-L237, core-libs/setup/ssr/optimized-engine/optimized-ssr-engine.ts:L59-L74
8. **Perché aggiungere un nuovo feature toggle in** `@spartacus/core` **rompe la compilazione della demo?** Perché i toggle dell'app sono tipizzati `Required<FeatureToggles>`, quindi ogni chiave dell'interfaccia deve comparire; inoltre una regola ESLint impone il valore `true`. — projects/storefrontapp/src/app/spartacus/spartacus-features.module.ts:L298-L298, projects/storefrontapp/eslint.config.mjs:L24-L30
9. **Perché i meta tag** `occ-backend-base-url` **di** `index.html` **non hanno effetto nella demo?** Contengono il placeholder, che le factory ignorano; e comunque `privateProviders`, registrati dopo `BaseCoreModule`, sovrascriverebbero `backend.occ.baseUrl` (e, con `undefined`, anche `media.baseUrl`). — projects/storefrontapp/src/index.html:L71-L82, core-libs/core/src/occ/config/config-from-meta-tag-factory.ts:L18-L41, projects/storefrontapp/src/app/private/private.providers.ts:L20-L31
10. **Che differenza c'è tra** `npm start` **e** `npm run dev:ssr` **rispetto all'SSR?** `start` usa il target `serve`, che applica sempre `noSsr`; `dev:ssr` lancia il build in watch e Node su `dist/storefrontapp/server/server.mjs`. — projects/storefrontapp/project.json:L214-L229, package.json:L150-L153

TAVOLA 47.1 **4.1 Dai flag di build alla struttura dell'app**

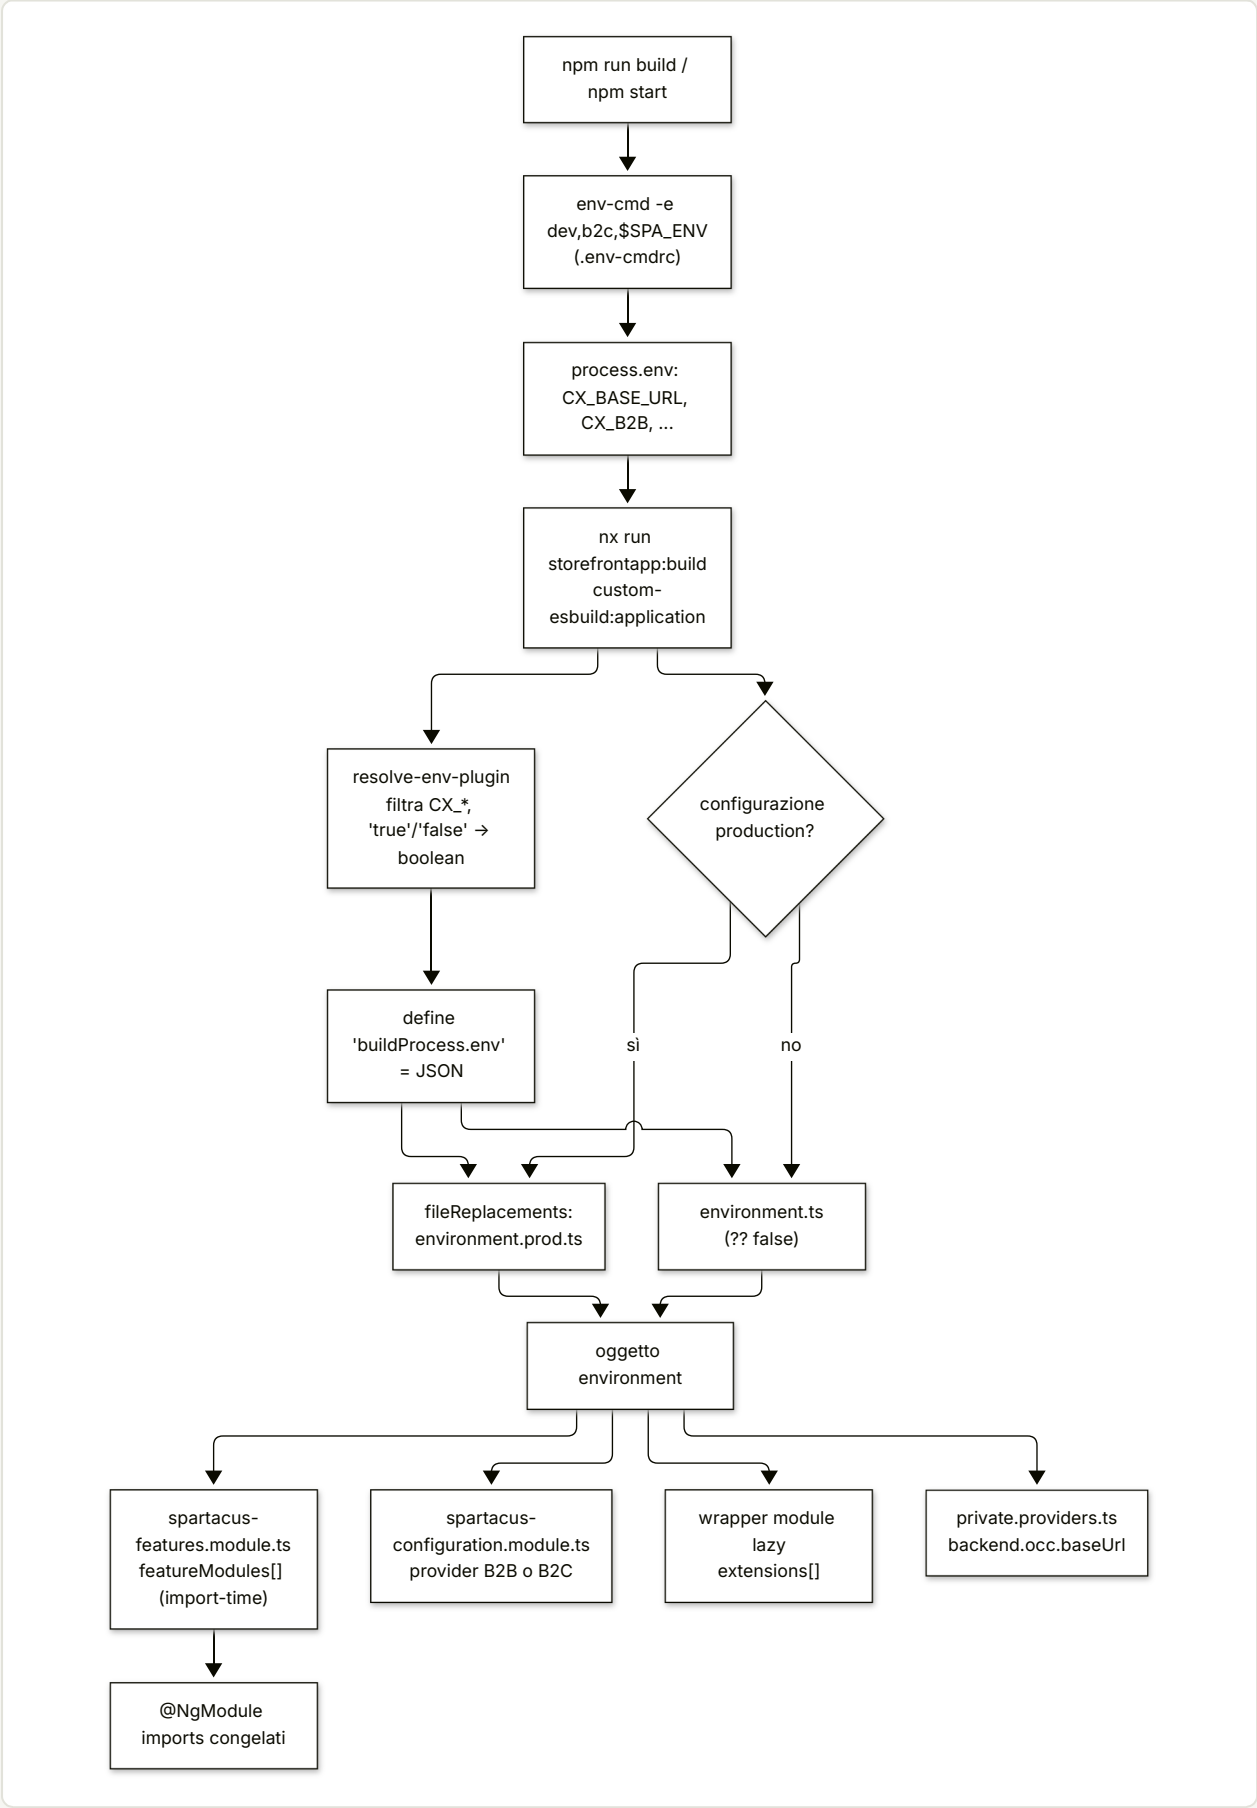

TAVOLA 47.2 **4.3 Richiesta SSR**

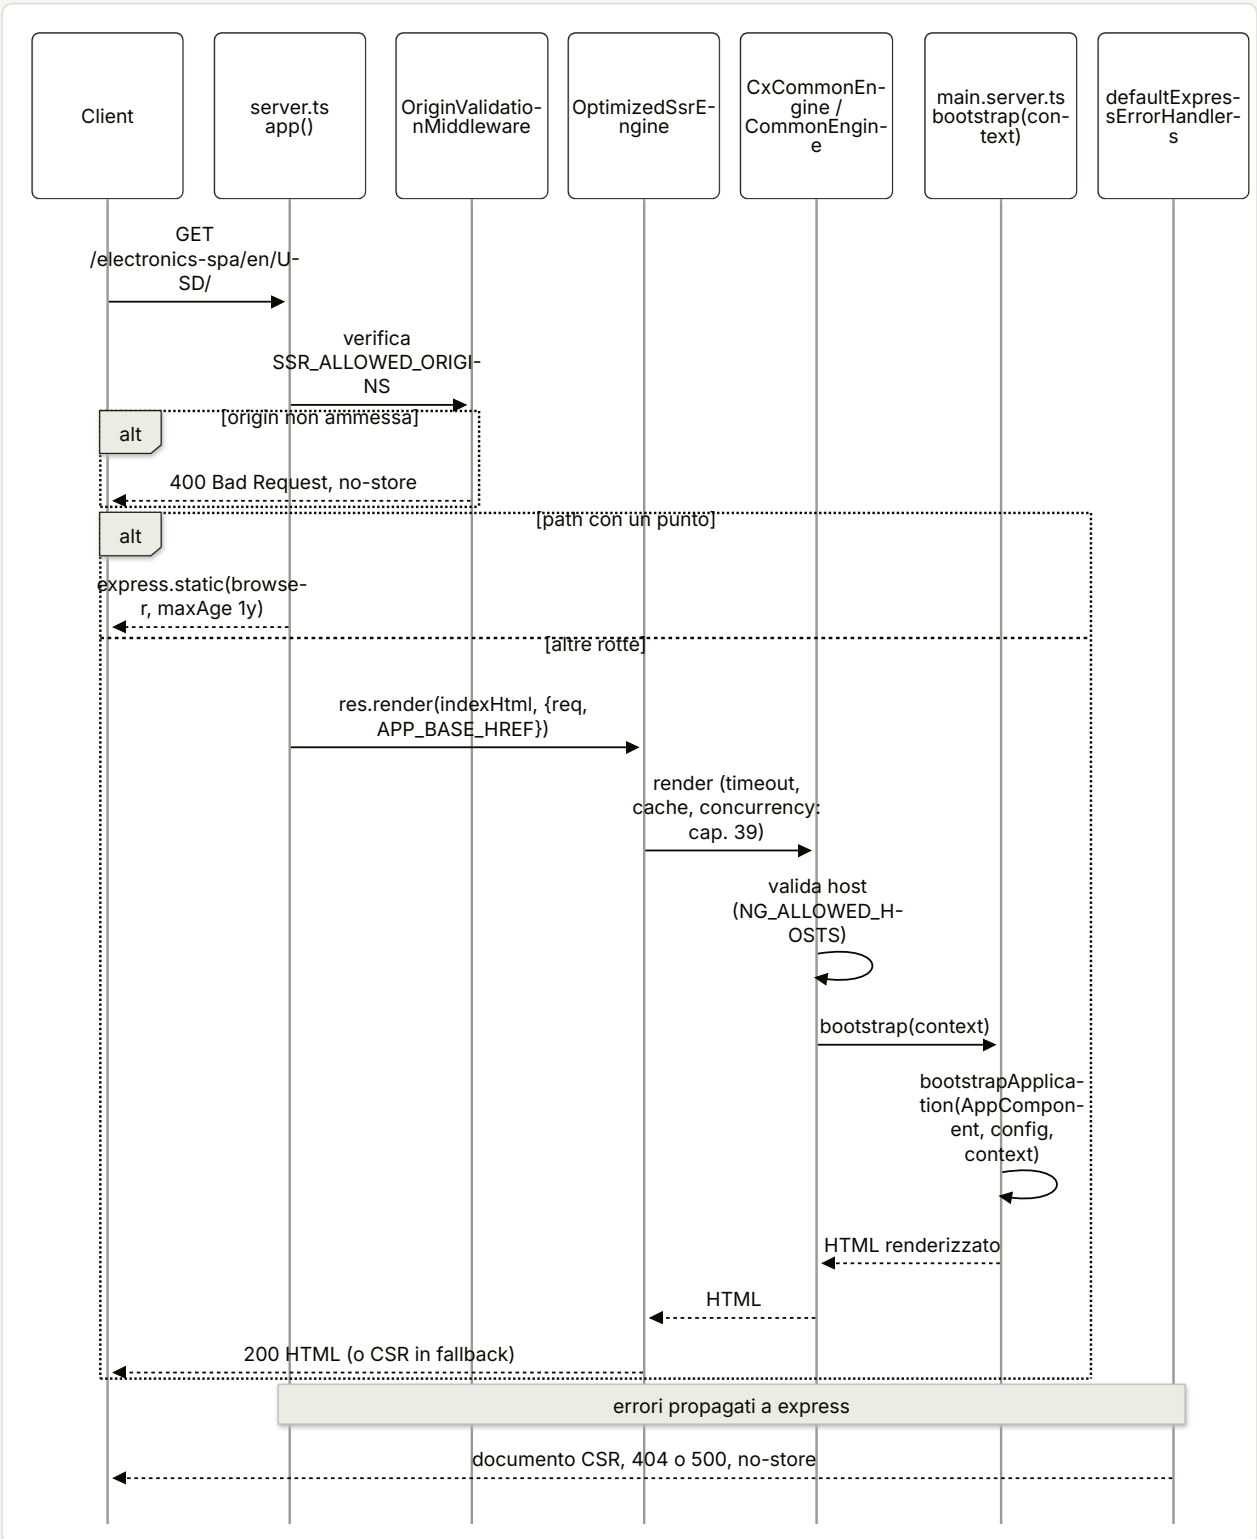

PARTE III

Ricette

50 Ricette: configurazione, DI, interceptor, eventi

51 Ricette: componenti CMS, outlet, route e layout

52 Ricette: OCC, adapter, converter, endpoint, meta resolver

53 Ricette: feature lib lazy, carrello/checkout, stili, traduzioni

54 API pubblica vs interna, upgrade, anti-pattern, checklist upgrade-safe

50

Ricette: configurazione, DI, interceptor, eventi

Override di config, sostituzione di servizi e facade, interceptor ed error handler, eventi custom.

10. Come fare debug
11. Domande di autoverifica

Riferimenti allo SHA `5b7a1c2bf2808d7380bc20596d10f4fa710c3da1` (vedi 00-meta).

1. A cosa serve e perché esiste

Questo capitolo raccoglie le personalizzazioni "trasversali" di uno storefront Spartacus, quelle che non riguardano un componente o una feature specifica ma il modo in cui l'applicazione viene assemblata:

- **configurazione**: sovrascrivere i default delle librerie, calcolare config con una factory, definire una config tipizzata per il proprio codice, leggerla nel momento giusto;
- **dependency injection**: sostituire un servizio root caricato subito (eager) o l'implementazione di una facade caricata in lazy loading;
- **HTTP**: aggiungere un interceptor e personalizzare la gestione degli errori HTTP;
- **eventi**: definire, emettere e ascoltare eventi custom, anche derivati da altri eventi o da action NgRx.

Ogni ricetta (sezione 3) segue lo stesso schema: quando usarla, un esempio di codice che importa **solo** simboli esportati dai `public_api.ts` dei pacchetti `@spartacus/*` (oltre ad `@angular/*` e `rxjs`), i file sorgente che rendono possibile il meccanismo, i limiti. La regola "solo API pubblica" non è estetica: la superficie pubblica di `@spartacus/core` è esattamente quella che `core-libs/core/public_api.ts` riesporta dai barrel delle singole aree (config, event, lazy-loading, state, util, http, occ, auth, global-message, window, logger) — `core-libs/core/public_api.ts:L10-L36`. Un simbolo che non compare in quella catena (per esempio `configFactory`, `MergingSubject` o `CONFIG_INITIALIZER_FORROOT_GUARD`) è interno e può cambiare senza preavviso — `core-libs/core/src/config/index.ts:L7-L19`, `core-libs/core/src/event/index.ts:L7-L8`, `core-libs/core/src/config/config-initializer/index.ts:L7-L14`. Il tema è approfondito in 54 — API pubblica vs interna.

Le ricette presuppongono i meccanismi spiegati nella Parte I e II:

- DI Angular (multi provider, `providedIn`, `useExisting`/`useClass`, ordine di elaborazione dei provider): 01 — Dependency Injection;
- `HttpClient` e interceptor Angular: 06 — HttpClient e interceptor;
- config di Spartacus (chunk, `deepMerge`, initializer, validator, config unificata): 11 — Configurazione;
- feature module lazy, `featureModules`, `UnifiedInjector`: 12 — Feature module e lazy loading;
- facade, `facadeFactory`, `EventService`, `StateEventService`, query/command: 20 — Facade, command/query, eventi;
- endpoint OCC e `OccEndpointsService`: 21 — OCC;
- `AuthInterceptor` e `AuthHttpHeaderService`: 22 — Autenticazione;
- `HttpErrorHandler` e global message: 41 — Errori e global message.

2. Mappa dei file

File sorgente che abilitano le ricette (non file da modificare: le ricette si applicano nel codice dell'applicazione).

PATH	RUOLO
`core-libs/core/public_api.ts`	Superficie pubblica di `@spartacus/core`; blocco AUGMENTABLE_TYPES con `Config` (L38-L40)

PATH	RUOLO
core-libs/core/src/config/index.ts	Barrel config: provider helper, token, `ConfigModule`, `ConfigurationService`, initializer, validator
core-libs/core/src/config/config-tokens.ts	`Config`, `DefaultConfig`, `RootConfig`, `ConfigChunk`, `DefaultConfigChunk` e factory di merge
core-libs/core/src/config/config-providers.ts	`provideConfig`, `provideConfigFactory`, `provideDefaultConfig`, `provideDefaultConfigFactory`
core-libs/core/src/config/utils/deep-merge.ts	Algoritmo di merge (oggetti ricorsivi, array sostituiti)
core-libs/core/src/config/services/configuration.service.ts	Config unificata con i chunk dei moduli lazy (`unifiedConfig$`)
core-libs/core/src/config/config-initializer/config-initializer.service.ts	`getStable(...scopes)`
core-libs/core/src/config/config-validator/config-validator.ts	`provideConfigValidator`, `ConfigValidator`
core-libs/core/src/features-config/config/features-config.ts	Flag deprecato `disableConfigUpdates`
core-libs/core/src/lazy-loading/facade-factory/facade-factory.service.ts	Proxy delle facade lazy: risoluzione dell'implementazione dall'injector del modulo lazy
core-libs/core/src/lazy-loading/feature-modules.service.ts	`isConfigured`, risoluzione degli alias di feature
core-libs/core/src/lazy-loading/lazy-modules.service.ts	Creazione dell'injector del modulo lazy (parent = root o dipendenze)
core-libs/core/src/lazy-loading/unified-injector.ts	`getMulti`: multi provider di root + moduli lazy
core-libs/core/src/auth/user-auth/services/auth-http-header.service.ts	Servizio root delegato da `AuthInterceptor` (esempio di override eager)
core-libs/core/src/auth/user-auth/http-interceptors/auth.interceptor.ts	Interceptor auth che delega a `AuthHttpHeaderService`
core-libs/core/src/global-message/http-interceptors/http-error.interceptor.ts	Sceglie l'`HttpErrorHandler` applicabile tra root + lazy
core-libs/core/src/global-message/http-interceptors/handlers/http-error.handler.ts	Classe base astratta degli handler di errore
core-libs/core/src/util/applicable.ts	`Priority`, `resolveApplicable`
core-libs/core/src/occ/services/occ-endpoints.service.ts	`getBaseUrl()` per riconoscere le chiamate OCC
core-libs/core/src/event/event.service.ts	`register`, `get`, `dispatch`
core-libs/core/src/event/cx-event.ts	Classe base `CxEvent`
core-libs/core/src/event/utils/merging-subject.ts	Sottoscrizione lazy alle sorgenti
core-libs/core/src/state/event/state-event.service.ts	Action NgRx → eventi
core-libs/core/src/util/create-from.ts	`createFrom(type, data)`
core-libs/storefront/events/navigation/navigation.event.ts	`NavigationEvent` (base per eventi di pagina derivati)

PATH	RUOLO
angular:packages/core/src/di/r3_injector.ts	Multi provider (push) vs single provider (sostituzione); record esplicito vs `providedIn`
angular:packages/core/src/di/provider_collection.ts	Ordine: provider degli `imports` prima dei `providers` del modulo
angular:packages/core/src/render3/di.ts	~~e~~`getInheritedFactory`: sottoclassi senza costruttore
angular:packages/common/http/src/interceptor.ts	Catena degli interceptor DI, ordine, cache
angular:packages/common/http/src/backend.ts	`HttpInterceptorHandler`: catena costruita dall'injector root
projects/storefrontapp/src/app/app.config.ts	`provideHttpClient(withFetch(), withInterceptorsFromDi())`
projects/storefrontapp/src/app/spartacus/spartacus-configuration.module.ts	Esempi di `provideConfig`/`provideConfigFactory` nell'app demo
projects/storefrontapp/src/app/spartacus/features/order/order-wrapper.module.ts	Wrapper module lazy con estensioni (modello per override di facade)

3. Come funziona passo per passo

Le ricette sono undici. Per ogni simbolo `@spartacus/*` usato negli esempi è indicata la catena di export dal `public_api.ts` del pacchetto fino alla definizione. Tutti gli esempi sono **illustrativi e non presenti nel repo**: sono modellati sugli usi reali citati nella sezione 5. Nomi di classi/file inventati per gli esempi sono scritti in corsivo nel testo.

3.1 Ricetta 1 — Sovrascrivere la configurazione di Spartacus con `provideConfig`

Quando usarlo

Quando si vuole cambiare un valore di default di una libreria (URL del backend, route, `featureModules`, flag `pwa`, ecc.) dal codice dell'applicazione. È lo strumento standard: le librerie forniscono i propri valori come *default config*, l'applicazione come *root config*, e la root vince sempre — core-libs/core/src/config/config-tokens.ts:L10-L12, core-libs/core/src/config/config-tokens.ts:L49-L62.

Esempio

Esempio illustrativo, non presente nel repo.

```ts
// app/spartacus/custom-config.module.ts (esempio illustrativo, non presente nel repo)
import { NgModule } from '@angular/core';
import { CmsConfig, provideConfig } from '@spartacus/core';
import { ORDER_FEATURE } from '@spartacus/order/root';

@NgModule({
  providers: [
    // 1. override puntuale: deepMerge ricorsivo sugli oggetti
    provideConfig({
      backend: {
        occ: {
          baseUrl: 'https://api.example.com',
```

```
        },
      },
    }),
    // 2. override di una chiave di featureModules (cast tipizzato, come nell'app demo)
    provideConfig(<CmsConfig>{
      featureModules: {
        [ORDER_FEATURE]: {
          module: () =>
            import('./order/custom-order-wrapper.module').then(
              (m) => m.CustomOrderWrapperModule
            ),
        },
      },
    }),
  ],
})
export class CustomConfigModule {}
```

Il modulo va importato **dopo** i moduli feature che configurano le stesse chiavi (o i provider vanno messi nei `providers` dell'`AppModule`, elaborati dopo tutti gli import).

Catena di export:

- `provideConfig`: core-libs/core/public_api.ts:L15-L15 → core-libs/core/src/config/index.ts:L9-L9 → definizione core-libs/core/src/config/config-providers.ts:L18-L27.
- `CmsConfig`: core-libs/core/public_api.ts:L14-L14 → core-libs/core/src/cms/index.ts:L8-L8 → core-libs/core/src/cms/config/index.ts:L7-L7 → definizione core-libs/core/src/cms/config/cms-config.ts:L128-L129.
- `ORDER_FEATURE`: feature-libs/order/root/public_api.ts:L9-L9 → definizione feature-libs/order/root/feature-name.ts:L7-L7.

Perché funziona (file sorgente)

- `provideConfig(config)` restituisce un provider `multi: true` su `ConfigChunk` — core-libs/core/src/config/config-providers.ts:L18-L27.
